LLANELLY.—At the meeting of the Estate Committee of the Town Council on Wednesday last it was decided to accept the offer of Mr. J. C. Howell for the purchase of the Council's Provisional Electric Lighting Order.

MANCHESTER.—It is stated that, undeterred by the abortive example of Glasgow, a number of leading business men in Manchester are signing a requisition calling upon the Corporation to inaugurate an independent telephonic system for the city. It is stated that a committee has been formed, and that the requisition has already received over 1,000 signatures. The requisitionists complain that the National Company's system is much too expensive, and that there is reason to apprehend a further increase in its charges.

MIDSOMER NORTON.—The Surveyor reported at the last meeting of the District Council that he had received two applications from electric lighting companies to light the town electrically. The Council, however, decided to advertise for lighting tenders.

PEMBROKE.—At the last meeting of the Town Council a deputation, consisting of Messrs. Ford and Baker, had an interview with the Council on the question of lighting the town by electricity. It was decided that Mr. H. A. Jones-Lloyd, Chairman of the Gas Committee, should confer with Mr. Baker upon the details of the scheme, and the result of their conference is to be reported at the next meeting. A meeting of ratepayers is to be convened for the purpose of protesting against the Corporation entering into any agreement with a syndicate about to be formed for lighting the streets electrically. The *South Wales Daily News* states that it understands the syndicate will consist of local men, "some of whom are members of the Corporation, and they expect to realise a profit of not less than 25 per cent." The ground of opposition is that the Corporation should retain the lighting of the streets in their own hands.

SHEFFIELD.—A special meeting of the City Council was held on Tuesday to discuss the tramway question. The lease of the existing Tramways Company expires in July next, and there is a strong feeling against renewing it, as it is considered the lines should be under the management of the Council. The Sheffield District and Rotherham Tramways Company is promoting a Bill in Parliament for power to construct an improved system of tramways on the overhead system. The Parliamentary Committee recommended the Council to oppose the Bill, and, after a long discussion, it has been decided to adopt this course.

SOUTHPORT.—The Town Council have sanctioned an expenditure of £4,000 for putting down additional plant at the electricity station.

STOURPORT.—A meeting of ratepayers was held at the Town Hall last week for the purpose of considering the resolution which had been passed by the District Council with regard to the construction of an electric tramway between Kidderminster and Stourport. The matter was discussed at considerable length, and a resolution in favour of the scheme was adopted.

WREXHAM.—At the meeting of the Town Council on Tuesday it was resolved that it was not desirable to grant any further extension to the Wrexham Electric Light Company under the provisions of its Electric Lighting Order.

SMOKING CONCERT.—To-night (Friday) at eight o'clock, at the St. James's Hall Restaurant, Regent-street, London, W., a smoking concert of the Electro-Harmonic Society takes place ; an excellent programme is provided under the musical direction of Mr. T. E. Gatehouse and Mr. A. E. Izard. The artistes include Mr. Malweyn Humphreys, Mr. Albert James, Mr. David Hughes, and Mr. Edward Kent, in addition to the popular directors of the concert.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

COMPANIES' MEETINGS AND REPORTS.

Eastern Telegraph Company (Limited).

The forty-seventh half-yearly ordinary general meeting of this Company was held on Thursday, January 23, 1896, under the presidency of the Most Hon. the Marquis of Tweeddale (the Vice-chairman).

The SECRETARY (Mr. George Draper) having read the notice convening the meeting and the minutes of the last general meeting, which were confirmed by the present meeting and signed by the Chairman as correct,

The CHAIRMAN: Gentlemen, I regret very much to say that our respected Chairman, Sir John Pender, is confined to his house to-day. I hope the indisposition from which he is suffering will pass away speedily, and I believe that a little rest from his arduous labours, and, perhaps, a visit to a more genial climate, will restore him to his usual good health. Fortunately for me I shall have, I believe, very little difficulty in recommending the approval of the report and accounts. The half-year which is under review to-day is the most satisfactory one that this Company has ever experienced. It is distinguished by two very satisfactory features. One is the large increase in the receipts, and the other is the decrease in the expenses. In the figures which I shall now refer to this will be fully borne out.

The gross revenue for the half-year under review amounted to £409,780, as against in the corresponding period of 1894 £362,557, or an increase of £47,223. An analysis of the message receipts from the various sources shows a satisfactory increase in nearly all classes of traffic, but the principal increase is in the traffic with West Australia and South Africa, which is due to the activity which has taken place in the gold-mining markets. With regard to the traffic with South Africa it is satisfactory to note that, notwithstanding the large reductions made in the tariff, an increase has taken place on the value of the traffic at the former rates, but as this is entirely due to special circumstances we can hardly count upon its being maintained.

The total ordinary expenses for the half-year ended September 30, 1895, amounted to £96,704, as against, in the corresponding period of 1894, £97,533, or a decrease of £829. The details of increases and decreases in the various headings of the accounts are as follows: The general expenses in London were £8,888, as against, in the corresponding period of 1894, £8,493, or an increase of £395. The principal increase will be found in salaries, rent, and fuel and light, and repairs and renewals of furniture, due to the additional number of staff and increased office accommodation required to cope with the greater volume of business. The working expenses at stations were £80,400, as against in the corresponding period of 1894 £79,316, or an increase of £1,084. Many satisfactory decreases are shown in several of the items under this head. Increases are mainly due to the salaries, lodging allowances, and other accounts more directly affected by the additional traffic which had to be carried. We have given the usual annual promotions to the permanent members of our staff, in accordance with the principle laid down by the Board, and this is an increase which I am sure that no one here will begrudge to those gentlemen. The number of staff at the stations in September, 1895, was 746, as against in September, 1894, 726, or an increase of 20. So long as we can show an increase in the revenue of the Company, and at the same time keep the total ordinary expenses within reasonable limits, I think you will agree with me that it is a very satisfactory position to be in.

Notwithstanding, as I have already pointed out, a considerable increase in the revenue this half-year, the total ordinary expenses actually show a decrease, as I have said, of £829. Although every care is exercised in controlling the working expenses, you must not be surprised if at some future date the figures are increased. Our business, in fact, is growing rapidly, and the increase is so large that an augmentation in the expenses must be contemplated by you.

Digitized by Google

Turning now to the expenses attending repair and renewals of cables, they amounted to £47,165, as against in the corresponding period of 1894, £43,709, or an increase of £3,456. This, as you all know, is a very uncertain item in the accounts of a submarine telegraph company. It is a very fluctuatitem. Some half-years the cost of repairs is larger than at other times. This half-year these expenses have been slightly larger, but perhaps in the coming half-year they may be less. As regards our ships, we believe that the greatest economy is achieved by keeping them in a state of the highest efficiency, but you cannot keep ships in a high state of efficiency without spending a good deal of money. We are enabled by this means to restore communication in the shortest possible time, thus saving the Company in many cases loss of traffic, and at the same time maintaining a good and efficient service to the Government, the Press, and the telegraphing public generally. I think the repair to the Eastern and South African Company's Cable between Aden and Zanzibar, which was so promptly effected by one of our ships during the late crisis in the Transvaal, affords a satisfactory proof of the efficiency of our service, if any proof were required. As another example of the energy with which the Company deals with the restoration of communication in the event of interruptions of traffic, I may mention a case which has lately occurred near Delagoa Bay. The cable steamer "Great Northern," which is usually stationed at Cape Town, was ordered to Zanzibar with instructions to call at the various ports *en route* in case of any break occurring during these troublous times. The ship arrived at Delagoa Bay on the 18th inst., and the cable became interrupted the following day. The ship, however, being within 29 miles of the break, the line was promptly repaired, and communication by the cable restored. The traffic in the meantime passed over the land lines to and from Delagoa Bay.

Full details of the work done by our ships during the half-year will be found on page 6, Abstract C, and I think a perusal of those details will justify the immense importance we attach to maintaining our ships in a high state of efficiency and ready for any emergency. With respect to that expenditure on the ship "Amber," I may mention that notwithstanding the extensive repairs and general overhaul which that vessel required, the expenses of which are included in this half-year's accounts, the total expenses of the ship are little more than they were in the corresponding period of 1894.

The next item with which I have to deal is the depreciation of spare cable, which amounted to £3,423, as against in the corresponding period of 1894, £4,815, or a decrease of £1,392. As previously explained, this item must vary according to the stock of cable in our tanks from time to time. After providing the usual amount for interest on debentures and debenture stock, and the usual two quarterly dividends, we are enabled to carry £10,000 to the maintenance ships' reserve fund, £50,000 ot the general reserve fund, and the balance of £49,352 is carried forward to the next half-year—a result which I think justifies what I have said with reference to the prosperous condition of your Company. We have applied a further sum of £50,000 from reserve fund in reduction of the cost of the Aden-Bombay No. 3 cable, leaving a balance of £70,000 still to write off; but I am glad to say that the cost of this cable will have been wholly applied to reserve fund when we put before you the accounts to the end of our financial year up to March 31st next.

The value of our investments on account of reserve fund at September 30th last amounted to £423,000 but they showed an appreciation of nearly £60,000, so that altogether the accounts presented to-day may fairly be considered as very satisfactory. With respect to the condition of our cables, I am glad to be able to say that, generally speaking, they are in good working order; but they are, as you know, of all ages and all lengths, and in seas differing very much in their condition with respect to cable-laying. You are also aware of the numerous breaks and interruptions that occur in them. All this, taken together, should warn us that we should add—we are, in fact, bound to add—to our reserve fund, which is still, in the opinion of all whose opinion is worth having, in a very inadequate condition. The general reserve fund amounts to £472,786, but it ought to be something like double that before we can consider it in a satisfactory state.

And now, gentlemen, I think it will interest you to know the actual facts with reference to our recent interruption on the east and west coasts of Africa. On December 24th the Aden-Zanzibar cable became interrupted. We had two ships available for its repair—one belonging to the Eastern Company, which had just left Suez and was on its way to Aden; the other one, belonging to the Eastern and South African Company, was stationed at Cape Town. The Eastern and South African Company found that by hiring the Eastern Company's ship a saving of about a week in restoring the cable would be effected, and orders were immediately given for the Eastern Company's vessel to proceed to the spot. The Aden end was hooked at the second sweep, and communication was restored via the East Coast on the evening of Saturday, January 4th. Meanwhile events had happened in the Transvaal of which you are all well aware, and our West Coast route had been called upon to perform, not only the whole of the ordinary traffic, but also of an enormous amount of additional traffic. Until the morning of December 30th the West Coast line was able to keep up to the work, but on the news of Dr. Jameson having crossed the Transvaal frontier, the line was occupied almost entirely by telegrams sent by and to European Governments. It may not be generally known that Governments have the right under the International Telegraph Convention, of priority of transmission for all their messages, and this particular traffic was transmitted without exceptional delay. Immediately the East Coast route was restored the delay began to diminish, and on January 10th we had completely recovered our normal working, which was owing not only to our having two lines available, but also to the cessation of the special Government traffic. It was a time of great anxiety for us, as you may easily suppose. We desired, above everything, to be absolutely fair, and to treat the whole of our traffic in accordance with telegraph law, and I cannot help saying that I think we succeeded (hear, hear). At any rate not a single complaint, as far as I am aware, has come from our own Government. On the contrary, I have reason to think our own Government is highly satisfied at the way in which their business was done. We have also not received any complaint from any other Government, foreign or otherwise, who, of course, have very large and important interests in connection with South Africa. I think I have said all that is necessary to recommend to you the adoption of our report and accounts. I think we may look forward to the coming half-year with confidence. The war clouds are lifting in every direction, and traffics continue good, reflecting, I believe, the greatly improved condition of business and commerce. With these observations I beg to move the adoption of the report and accounts.

Lord SACKVILLE A. CECIL: I second that.

The CHAIRMAN: It has been moved and seconded—

"*That the report and accounts be received and adopted.*"

Before putting the motion I will invite any observations which gentlemen opposite may wish to offer to the shareholders.

Mr. BAINES: Brother shareholders, before making any remarks on the report I must express my regret at hearing that Sir John Pender is unwell. I trust that this will be of a very temporary character, and that he will soon be among us once more. I daresay the entire meeting will only be too ready to ask some gentleman on the Board to convey to Sir John Pender our expression of sincere regret at his indisposition. We have again to congratulate ourselves on having had a very good half-year—better than ever. In fact, that has been the tenour of our reports for some little time, but I regret to say that notwithstanding that our dividend never increases. I have been connected with this Company for a quarter of a century or more, and I notice that the dividend is very stationary. You are doing very considerable business, and are rendering great services to the public, and after such a length of time, and after doubling, triplicating, and quadrupling our cables, it stands to reason that we shareholders, who have borne the brunt of the battle, ought to look to getting some benefit ourselves. The Preference shareholders are well secured, and so are the Debenture holders, and we have to bear considerably more burden than appears on the surface. There are certain benevolent funds to which we contribute which come entirely from the Ordinary shareholders. I do not think that the Debenture holders or Preference shareholders have ever been called upon to subscribe to that fund, which is thought to be a very necessary one. The large sum of £50,000 is carried to the reserve fund, and a very large sum is carried forward, but I think that the Directors ought to have taken the interests of the Ordinary shareholders into consideration. I regret that his Lordship has not said anything touching on their interests either in the present or the future. I think that that is a matter of regret. There are several items of satisfaction brought to our notice on this occasion. The reduction in the expenditure is a good feature, and I wish to impress on the Board, as I have done before, the necessity of taking into consideration the interests of the Ordinary shareholders. I think that the Company has such an amount of money at its disposal that it might do something for them. We see our stock standing in the market at 17, or a trifle over. Perhaps the Directors find themselves in some difficulty as regards increasing the dividend on account of clamour from the Press or from those who do business with us, but I should think that they might devise some scheme by which the increase of dividend would not be apparent (laughter). I think that in a commercial enterprise such as ours 6½ per cent. is not such a very brilliant return. There is, however, that point which I have just mentioned to be guarded against. I would therefore suggest to the Board a scheme something of this character. We see our Ordinary stock standing at something like 17. Would it not be possible for them to give an additional share for each of the Ordinary shares, and thus let us have some benefit from the position which the Company has attained to? If the Board find that they cannot do that, there is a sum of about £3, the difference between £7 and £10, which each shareholder might be called upon to pay. That might be carried to the reserve fund, which would in that way be strengthened very materially. What would it matter if we got 4 per cent., as, it being on two shares instead of one, we should be getting 8 per cent., which I think is only a fair return doing the work which the Company does not only in serving commerce, but other interests. This is really the crux of the whole question. I as a shareholder am not altogether satisfied with the present state of things. I do not say that what is paid is a small or despicable dividend, but I say that a company like this, doing the work it does, having the capital it has at its command, and serving the public as it does, the shareholders certainly are deserving of a better return than 6½ per cent. Why, some ordinary banks of very recent formation pay dividends of 8 per cent. and 10 per cent., and a commercial company, considering the risks we run, ought to have more than 6½ per cent, which is not enough. I trust it will not be necessary for me to propose a resolution, which, however, I think I shall do, unless some notice is taken at a future meeting of the observations I have now made. I hope that it may not be necessary for me to do so, but that the Board will themselves take this matter into consideration, and deal liberally with the Ordinary shareholders.

After a few observations from Mr. W. GOODSALL on the subject of the reserve fund and of increasing the dividend,

Mr. JOHN NEWTON said: I am afraid I shall be contrary to the general sense of the meeting, judging from the remarks which have been made, as regards the question of the dividend. I do not consider it a small one, but a very good one (Oh!). I want, however, in the first place, to give expression to the universal sentiment of regret felt by us at not having our own chairman with us. He has been with us so long that we miss him very greatly. It is, however, to be hoped that he will soon be among us again restored to health. Reverting to the question of dividend, I think the Company presents to the investor such a remarkable career of success that we can well afford to leave the management of the business and of its

Digitized by Google

finances to the Board. Certainly I trust that there will be no manipulation of the stock in the direction of "watering" it and trying to obfuscate and deceive foreign Governments. As if such a thing were possible! If you were to give me an extra share for every share I hold, do you think that the Government or the public would not know what you were doing and that you were really paying me 8 per cent. or 10 per cent. if you gave me 4 per cent. or 5 per cent.? It would be well known to the experienced men who attend the Telegraph Conference, who are certainly impelled in their action by the large dividends which are talked about and paid. It is very remarkable that the gentleman who has occupied our time, and done so for much longer than I, should try to put me down by calling out "Time." He ought to know that I should not think of sitting down for any such cry (laughter). I think the position of the Debentures and Preference shares in the market is an indication to the shareholders that they are very well served, and they see their Ordinary shares standing at 17, or 70 per cent. premium. Bear in mind that you have to deal with competitors if you show a very large dividend. What is the use of doing anything that would induce others to establish other cables which would compete with us? What has been the case with the Anglo-American Telegraph Company through showing such large earnings in the past? What has been the result except that of bringing about a competition which is as severe as it is possible to find in any business, keen as competition is in everything? I therefore say leave well alone, especially when that well is being attended to by such successful Directors as we have. Surely when the Chairman tells you that it is necessary to increase your reserve fund you will take advantage of exceedingly good years to make the increase which is necessary in order to ensure your dividend being maintained. As solid quarterly dividend-paying companies there are none to equal the Eastern and Eastern Extension, I trust that there will be no attempt to split or "water" the stock, as it would be thoroughly well known what that would mean.

Mr. WOOD: I think that our friend hardly understood what Mr. Baines said; but I understood that his idea in doubling the shares was to carry a larger amount, if necessary, to the reserve fund, which would place us in a better position even than we are now in. Shareholders in the Aerated Bread Company often have shares issued to them in proportion to their holdings. I think that if £3 a share were transferred to our reserve fund it would be a considerable help to us. All these shares would be taken up and the shareholders would derive a benefit, whereas at present they cannot get any benefit unless they sell out, and they do not want to do that. I think that the idea of Mr. Baines is a very good one; but it is merely a suggestion. We have a right on this side to suggest what we like, and what Mr. Baines has suggested would improve the position of the shareholders and strengthen the Company in the direction of the reserve fund.

The CHAIRMAN: Gentlemen, let me assure you that I shall take an opportunity of conveying to our Chairman the kind expressions which have fallen from the speakers who have addressed the chair to-day, and whose remarks have been so cordially received by the whole body of shareholders (hear, hear). Mr. Baines has repeated the remarks which he made on a former occasion, and complained that the dividend is not sufficiently large; but I would remind him, in the first place, that this is the half-yearly meeting, and that at the half-yearly meetings the dividend is always very much less, or it is always expected that the dividend at the close of the financial year will be larger than that for the first half of the year. His remarks and suggestions, however, will, of course, receive, as they have always received, the careful consideration of the Board, and if we can see our way to meet his wishes on the subject of dividend without interfering with the policy which has been pursued over since this Company has been formed, we shall be very glad to do it. That policy may be stated in very few words—namely, in the first place, to keep our capital account as low as possible; in the second place to pay a fair dividend, and in the third place to build up an adequate reserve fund. I think we have fulfilled the first two conditions—that is to say, we have kept our capital practically stationary for a great many years, and we have paid, I think it must be admitted even by Mr. Baines, a fair dividend ever since this Company was started. It might be described as a liberal dividend. The third condition, however, has not been fulfilled; our reserve fund is not adequate, and it will take some time before it is. You must not suppose that this large gross revenue will always remain as large as it is at present. Suppose, for instance, a cable or cables are laid across the Pacific, that would affect our traffic very considerably. It is not impossible that that may happen in a shorter time even than we should like. When it does come off, which it is bound to do some day or another our traffics will be certainly affected, and it would take us all our time to compete successfully and profitably with our rivals in the Pacific. With respect to the suggestion to issue copies of the proceedings at the general meetings, we did at one time issue copies to the shareholders, but it was given up on account of the cost. It is not a very large sum, I quite admit, and probably it was given up at a time when we were not in so flourishing a state as we are in now. If we find that the shareholders generally would like a copy sent to each of them, we shall be very glad to meet their wishes in that respect, and with reference to the frequent breaking down of the Tangiers-Gibraltar cable, it is not due to want of care or trouble that the breaks take place. We do not like breaks because they cost us money. I do not think I have anything to answer with respect to the remarks made by Mr. Newton; in fact Mr. Newton has really done what I have attempted to do, and I believe he did it much better. He answered the criticisms in a very satisfactory manner, a manner very agreeable to the Board, because we take the same view as he does with respect to the matters commented on. Mr. Wood, I think, endorsed Mr. Baines's opinions, but, as I said before, Mr. Baines's opinions and suggestions will be considered by the Board, and shareholders must suspend their judgment until the close of the financial year. I think it is a peculiarity in this Board that the re-election of the Directors takes place in the middle of the year, or in the first half-year, instead of at the close of the year. Perhaps that led gentlemen to suppose that this was the closing half-year, but it is not so. The end of our financial year will be six months hence. I think I have answered all the questions which have been addressed to me, and I will now, with your permission, put the motion for the adoption of the report and accounts. That has been seconded by Lord Sackville Cecil. Those in favour of it will signify the same in the usual manner by holding up their hands. On the contrary. Carried unanimously. I have now to propose—

"*That Lord Sackville A. Cecil, who now retires, be and he is hereby re-elected a Director of the Company.*"

Sir ALBERT J. LEPPOC CAPPEL, K.C.I.E.: I beg leave to second that.

The CHAIRMAN put the motion in the usual way, and declared it carried unanimously.

Lord SACKVILLE CECIL: I am much obliged to you, gentlemen, for this renewal of your confidence.

The CHAIRMAN: I have now to move—

"*That George Garden Nicol, Esq., who now retires, be and he is hereby re-elected a Director of the Company.*"

I regret to say that Mr. Nicol is also indisposed, and not able to be present among us to-day. He has been attending our meetings regularly up to a very recent period. I only hope that his indisposition is merely temporary. As you know, Mr. Nicol, Sir John Pender, and myself are the three original Directors of this Company. I beg to move the resolution.

Lord SACKVILLE CECIL: I second that.

The CHAIRMAN put the motion in the usual way, and, having declared it carried, said: The only other business now is the election of auditors. That will be done by gentlemen in the body of the hall.

Mr. BAINES: It is my duty to move the re-election of the auditors. Generally speaking, I have had some remarks to make with respect to the audit of the accounts, because this is a matter of importance to shareholders to look after. Occasionally we see the false impression which auditors' certificates convey. The certificate of our auditors is certainly characterised by its brevity, for it simply says "Audited and found correct." Now that is very concise, and I hope it is satisfactory. I now beg leave to move the re-election of the auditors, Messrs. Deloitte, Dever, Griffiths and Co., and Messrs. Welton, Jones and Co.

Mr. WOOD: I have much pleasure in seconding that.

The CHAIRMAN put the motion, and having declared it carried, said: Gentlemen, that constitutes the business of the meeting.

Mr. NEWTON: It is not usual for these meetings to separate without passing a vote of thanks to the Chairman and his colleagues. I think they are entitled to a vote of thanks in this Company far more than they are in the case of some other companies. I therefore have much pleasure in proposing a vote of thanks to the Chairman and Directors for the successful way in which they have managed this Company throughout its long career.

Mr. GRIFFITH: I have much pleasure in seconding the resolution.

The motion was carried unanimously.

The CHAIRMAN: On the part of my colleagues and myself I beg to thank you, gentlemen, and I hope that we shall continue to deserve the confidence which you have been good enough to express towards us.

The proceedings then terminated.

City and South London Railway Company.

The twenty-third ordinary general meeting of the proprietors of this Company was held at Winchester House, Old Broad-street, on Tuesday under the presidency of Mr. Charles Grey Mott.

The SECRETARY (Mr. W. F. Knight) read the notice calling the meeting, and the seal was affixed to the register of shareholders.

The CHAIRMAN said: I now have to move the adoption of the report and statement of accounts. We have again, I am glad to say, to report that we have carried over three millions of people with perfect safety, and with almost absolute punctuality, during the past half-year. You will notice that there has been a decrease in the number of passengers, as compared with the corresponding period of 1894, of 103,000, but there is an increase in the numbers as compared with those carried in the June half-year of about 60,000. The decrease, as compared with those carried in the December half of 1894, is explained by two or three reasons. More than a year ago we increased the fares in order to diminish the overcrowding on the railway, and that had a very decided effect in decreasing the number of passengers. Then we had during the first three months of this half-year very fine weather, and it was exceptionally hot. As you are aware, this always has a prejudicial effect on the traffic of this line. The decrease at that time induced us to consider the question of revising the fares we had raised before, and we lowered them at one of the stations down to their old level. The result was that we immediately got an increase in the number of our passengers, and this compensated us for the loss we had had in the previous quarter, and resulted in our having a decrease only in the receipts for the half-year on passengers other than season-ticket holders of £350. On the other hand, the number of season tickets increased by 62, compared with the corresponding period of 1894, and the receipts from that source were £290 more. This gives us a net increase in our passenger receipts of £240 in the half-year. You remember that our object in raising the fares was to lessen the overcrowding which took place in the early morning trains especially. It had that effect, and the overcrowding decreased, but, unfortunately, as you know, it reduced our revenue in consequence. We have now partially recovered that decrease, and I hope that in the present half-year we shall show a decided increase both in number of passengers and receipts, but it has increased again the overcrowding of the trains. In order to meet that we have made an alteration at King William-street. It has proved a very difficult piece of work

Digitized by Google

but by the devotion and ability of our engineer, the difficulties have been got over, and those alterations, I am glad to say, are completed and are brought into use. The advantage there is that we can have two trains at once in the station, as we have at Stockwell, and therefore there is no waiting for the train. The passenger at once proceeds into the train without any delay of that kind, and we are already enabled to run several additional trains in the hour; and when all the appliances are in good working order, we hope to increase the number still further. This will enable us again to diminish the overcrowding, I hope, and give some better accommodation for passengers in the morning. Unfortunately at the present moment we have often to turn away a large number of passengers, and frequently delay those who travel, and that injures our traffic very considerably, because, as you know, people coming to the City want to be absolutely certain of the time at which they will arrive, and delays of that kind lead them to make fresh arrangements, so that they do not travel by us at all. It also affects the increase of the residential population on our line, because without these facilities they seek some other neighbourhood where they will obtain them. We have now, I think, done everything we can, with our present line, to meet the traffic and to provide accommodation for it. We hope that these new arrangements will enable us to keep pace, as far as we can, and to prevent any very great overcrowding for perhaps another twelve months; but it is only a temporary provision, and we feel that the time has now arrived when we can no longer delay proceeding with the additional accommodation we propose to provide to enable us to deal with the traffic. We have been very careful and cautious in not going on with this work while we could avoid doing so, and our experience at the present moment, I fear, is that we have been over cautious, and have delayed the matter too long, It is evident that no time should be lost in proceeding with our extension and in providing sufficient accommodation to deal with the traffic; and in our report we ask for your authority to proceed at once with that portion of the Islington extension which lies between its connection with the existing line and Finsbury Pavement, adjoining the Moorgate-street station of the Metropolitan Railway. To meet the additional trains we are now beginning to run, we have ordered new carriages, which have all been delivered, and they appear to be giving general satisfaction so far as they have been used. We have turned our attention especially to see if we could not possibly reduce the cost of working the line still further, and we have introduced a small new engine and dynamo into the engine house for that purpose, so as not to use so much current during the less busy hours in the day. By using this small engine we are able to save the expenditure of electric current and the consequent expenditure of fuel required to produce it. We are also about to erect a large condensing apparatus at Stockwell, which we are assured will save us considerably in the fuel consumed, and I trust that before we meet again we may be able to say that that has been the case. The condenser is now being made, and I hope will be fitted up before the summer. The new sidings at Stockwell are completed, and are just being brought into use. They will economise to a certain extent in not requiring the trains to be taken up and down the incline for their ordinary repairs. These are all the points, in connection with which we have been doing our best to decrease the cost of working the line as far as we can, and I hope that these new trains, on the other hand, will enable us to earn a little more revenue than we could otherwise get. We cannot, however, make this line a success until we get the extension carried out so as to enable us to convey the traffic, which is there ready for us when we are prepared to carry it. If you will turn to the accounts you will see in the case of the capital account that we have paid off the old terminable Debenture bonds to the amount of £9,400 in the half-year, and we have spent on capital account, on the new carriages, new engines and other matters £6,683, making a total on that account of £16,083. To enable us to do that we have issued Preference shares to the amount of £4,690, and have received in premiums on those shares £2,237, or a total of £6,927. In addition to that, as we were getting very poor interest on the balances at our bank, we reduced them as low as we could, and they are less by £6,740 than they were a year ago. We have other balances which have been increased, which give us a credit of £2,416, this making a total of £16,083, which is exactly the amount of the bonds and the expenditure. In turning to the revenue account you will see that the receipts from passengers are increased by £240, from parcels by £29, and from rent by £105. There are decreases, on the other hand, in transfer fees of £4, and in sundry receipts of £68, making a net increase of £302. With regard to the expenditure, the maintenance shows a decrease of £65, locomotive expenses £85, traffic expenses £50, general expenses £42, law charges £17, and rates and taxes £9. On the other hand, there is an increase of £97 in carriage repairs, and of £47 in passenger duty, making a net decrease in expenses of £124. The final result is that we have a net increased receipt of £302, a decreased expenditure of £124, and a decreased debenture interest of £337, or a total credit of £763. We have, however, a decreased bank interest of £20, and there is an increase in the preferential dividend—owing to the issue of these Preference shares to replace debentures—of £70. We are, therefore, better off by £673 in the half-year, which is very nearly equal to the increased dividend of ¼ per cent. You will naturally ask why we do not pay an increased dividend of ¼ per cent. The answer is that last year at this time we brought forward from the previous half-year a much larger balance than usual, and we took £417 to pay a dividend of 1¼ per cent. at that time. We have not that balance this half-year, and we have to find out of the receipts the £417 in order to give the same dividend as we paid last time. But we have done more than that. Instead of taking out of this fund £417 we have added to it £256, so that those two items together make the £673 which we have of increased receipts, and, therefore, although we appear as if we had made very little progress this half-year, we have really had a satisfactory increase in the relative earnings of the two half-years, which is nearly equal to ¼ per cent. Our working expenses this half-year have been 59·62 per cent., as compared with 60·9 per cent. in the corresponding period of the previous year, so that that is a definite decrease of more than 1 per cent. If you take off the cost of working the lifts, the railway expenses are 51½ per cent., against 52 per cent. in the December half of 1894. The receipts per train mile were 2s. 2d., or an increase of ¾d. per train mile, and the receipts per passenger were 1·80d., against 1·77d. a year ago. The locomotive expenses per train mile were 6·02d., against 6·03d. last half-year; and if you take off the cost of the carriage of coal, which other companies do not charge, it brings this item down to 4¾d. per train mile. I think I have already explained the reason why it is absolutely essential that we should go on and construct the extension of the railway. I am glad to say that we have made, so far as we can at the present moment, such satisfactory arrangements as regards the sites of the stations, which was the most important question at issue; and these arrangements make us pretty certain that we can carry that line through and complete it for the amount we stated this time last year as the estimated cost—namely, £280,000. Of course, it is absolutely impossible to say within a few thousands either one way or the other, but we hope we may carry out this work for less than that. We have taken the best estimates we can from engineers and others, and we believe that that extension can be carried out for this amount, and remembering that the length of the line is considerably over a mile, it will be done very cheaply if we do it for that figure. Seeing that we shall pass through and have to deal with the very busiest traffic in the world, perhaps, almost along its route, we cannot doubt for a moment that that extension will not only enable us to pay the interest on the Preferential shares we propose to issue to carry it out with, but will also leave us a large surplus to increase the dividend on the ordinary stock. I am sorry to say that we have lost the services of the engineer of this Company. Mr. Basil Mott has been with us ever since the line was making and ever since it has been opened as our engineer, and we are very sorry indeed to lose his services. At the same time we are also glad that he leaves us to take up a most important work in connection with the great Central London Railway which is now starting, and although we cannot but feel that we owe very much to his ability and devotion in the past, we feel that we must give him every good wish in the work he has undertaken. During the whole of the time he has been with us as engineer he has had under him a very able assistant in Mr. P. V. McMahon, and we felt that we could not do better in the interests of the Company than to appoint Mr. McMahon to succeed him. I trust that in the future I may be able to speak of Mr. McMahon in the same terms in which I am able to speak of his predecessor. As regards the Bill which we have introduced into Parliament, the powers under the Bill of 1893 for the extension to Islington will expire next August, making it necessary for us to introduce a Bill to extend the time, as we do not propose to proceed with the extension beyond Finsbury-pavement to the Angel, and it is for the purpose of obtaining an extension of time for the land required for that part of the line which we are not proceeding with at present that this Bill is introduced. It will not affect the proceedings we propose to carry on now, because we shall exercise the powers which now exist with respect to the sites we require for the proposed extension. We find also that in order to avoid interfering with the traffic of the streets in the High-street, Borough, and at the same time to enable us to get at and deal with the somewhat difficult junctions between the proposed new line and the existing line, which must be carried out without interfering with the traffic, it is desirable to sink a special shaft at that point of junction, and we have taken powers in this Bill to acquire a site for the sinking of that shaft in order to prevent our having to sink it in the street. We shall be able to get a site which will enable us to sink this shaft on property of our own. We also take power to sink a shaft a little further on in a corner of the street where there is no traffic passing. We have also certain other requirements in the Bill. We want to alter slightly at one of our City stations the mode of construction of the shafts for the lift. The Bill will come on afterwards at the special meeting. He concluded by moving the adoption of the report and accounts.

Mr. SAMPSON HANBURY seconded the motion, which was carried unanimously, and resolutions were afterwards passed declaring the full dividend of 5 per cent. on the Preference shares and a dividend at the rate of 1¼ per cent. per annum on the Ordinary stock, and re-electing the retiring Directors, Mr. Charles Seymour Grenfell and Mr. Edwin Tate—and the retiring auditor, Mr. James L. Oliver.

An extraordinary general meeting was then held.

The CHAIRMAN proposed—

"*That the additional capital sanctioned by the City and South London Railway Act, 1893, be, and the same is hereby created in 55,000 new Ordinary shares of £10 each, and 20,000 Preference shares of £10 each, bearing interest at the rate of 5 per centum per annum, and that the Directors be and they are hereby authorised to issue such shares in such amounts at such times, and on such terms and conditions as they may think fit. The holders of the Preference shares hereby created shall be entitled to vote on the same scale of voting as the holders of Ordinary shares.*"

This, he said, would create the 20,000 Preference shares which they proposed to use as set out in the Directors' report, which they had approved. They had very carefully considered the best mode of raising the money, and after discussing various reasons for and against, they thought it would not be desirable to create the capital at the present price of the Ordinary shares. The Preference shares of the Company were now selling at 50 per cent. premium, so that the Company would really only be paying about 3¼ per cent. on the money obtained by this issue, and they thought that they could not raise the capital they required at a lower rate than that. They would not think, while all this work was going on, of interfering in any way with the dividend on the Ordinary share capital until the line was opened and paying its own way. They therefore intended to issue the Preference

Digitized by Google

shares, payable by instalments, or such portions as they wanted, for they would only require the money gradually over a period of two or two and a-half years. They therefore proposed to issue these Preference shares in such a way that the dividend would not come before the time estimated for the opening of the line and its being worked for some time. That was their general idea. He then moved the resolution.

Mr. BARCLAY HEWARD seconded the motion.

Mr. THOMAS HANBURY, in the course of a lengthy speech, opposed the proposal. He went into a calculation, showing the time it would take to get by omnibus or on foot from the corner of Lombard-street to London Bridge in comparison with the time it would take to travel by the projected line, and maintained that one could walk the distance as quickly, or by going by omnibus could save three minutes by not using the line. Since the past year the Ordinary stock had fallen from about 50 to 41, and he held that this was attributable to the confidence of the public having been shaken by the expenditure which the Directors proposed. By the resolution now proposed £10,000 a year would be placed before the £7,500 a year, which was all that the Ordinary shareholders had to go upon for a dividend. He contended that the so-called extension was really a new undertaking, and that it should be so constructed, if it were constructed at all, the public being asked for the capital in the usual way. The Brighton Company would virtually have nothing to do with the proposed extension. Opposition would also be given to the Directors' proposal on account of its involving the removal of the ancient church at the corner of Lombard-street for the site of a station. He concluded by proposing the following amendment:—

"*That the placing of £10,000 per annum in front of £7,500 per annum, the only income at present available for the ordinary shareholders, is unjust to them, and therefore the proposed issue of £200,000 of 5 per cent. preference shares be not authorised.*"

Mr. J. T. MIDDLETON said that having consistently opposed the extension at previous meetings, and as his opinion remained unchanged, he would second the amendment. He thought the Directors should avail themselves of the powers they had under their Act, and make the proposed extension a separate undertaking, as he opposed the placing of such a large number of Preference shares in front of the Ordinary stock.

Mr. DRAKE pointed out that at the last meeting the Directors were authorised to proceed with the scheme, and he had no doubt that most of the points which had been raised by Mr. Thomas Hanbury had been considered by the Board.

Other shareholders having addressed the meeting,

The CHAIRMAN stated that as they had adopted the report, he could hardly deal with the question of the desirability of the construction of the line. The question before them now was as to the best mode of raising the money. Mr. Middleton thought that it ought to be raised by a separate undertaking, but this matter had been very carefully considered, and they believed that it would be very undesirable in the interests of the Company to do anything of the kind. It would lead to extremely complicated working, and might result in the separate undertaking running away with the whole of the profit and leaving this Company with the risk besides. The more they looked into the matter the more they were satisfied that the extension should be carried out by the Company themselves, and the Directors were quite satisfied that the proposal would result in a very satisfactory addition to the ordinary dividend. It must be remembered that this was not an ordinary steam railway, but an electric railway worked on totally different principles. There was one definite generating point, and the extension of an electric line did not mean the extension of the expenses of working in the same way as it did with an ordinary steam railway. That was a most important point. They could not stop safely as they were. Mr. Hanbury's calculations were quite wrong as to the time taken in going by the proposed railway as compared with doing the journey on foot or by omnibus. They were going to make a station for the Brighton and South-Eastern Companies' traffic at London Bridge, and they would have there an underground connection up to the platform of the Brighton Company. He had not the least doubt that they would get a very large traffic there. With reference to the church at the corner of Lombard-street, it was only within the last two or three days that any opposition had been expressed to their taking it. The opposition came from the City Church Preservation Society, which did not represent the Ecclesiastical authorities, who had no objection to the Company taking the church. So far as the spiritual wants of the metropolis were concerned, it would be an enormous advantage, because the money paid for the site would be used for constructing churches in poor and populous districts on the outskirts of London, where churches were required. With regard to the architectural aspect of the question, opinions differed, and his own view was that a great improvement would be effected by removing the church and placing on the site a much more handsome building. It was, however, too late to discuss this question now, for all their arrangements were completed. The Preference shares would be of the same kind as those already issued, and the shareholders must leave the Board to do their best to carry out the arrangements on the best financial conditions possible. He then put the amendment, which was lost, and the original resolution was afterwards carried by an overwhelming majority. Continuing, he proposed—

"*That the Directors be and are hereby authorised to exercise the borrowing powers of the Company authorised by Section 82 of the City and South London Railway Act, 1893, by the creation and issue of Debenture stock.*"

The motion was seconded and carried.

A special general meeting was afterwards held, and

The CHAIRMAN proposed a resolution approving a Bill to extend the time for the purchase of land for the purposes of the City and South London Railway Act, 1893, for completing the underground railway and works thereby authorised, empowering the Company to acquire additional lands, and for "other purposes."

The SOLICITOR (Mr. Donald McMillan) explained the salient features of the Bill.

Mr. D. YOUNG seconded the resolution, which was carried.

On the motion of Mr. DRAKE, seconded by Mr. MIDDLETON, a cordial vote of thanks was passed to the Chairman, Directors, and the General Manager, Secretary and staff.

St. James' and Pall Mall Electric Light Company (Limited).

The report of the Directors for the year ended December 31st last, which will be presented to the shareholders at the ordinary general meeting to be held at the offices, Carnaby-street Central Station, Golden-square, London, W., on Tuesday next, at 12.30 p.m., states that the Directors are pleased to state that the business shows a steady increase, and that the position of the Company has been considerably strengthened during the past year. The building extension in Carnaby-street has been completed and the station equipped with its full plant, and the working of this and of the supply generally has proved most satisfactory.

The actions instituted by the Attorney-General on behalf of the Parish and by the Windham Club, alleging nuisance from the plant at Mason's yard Station, have been arranged. The Directors have disposed of the greater portion of the engine plant at Mason's-yard Station and are replacing it by machinery of a similar description to that in use at the Carnaby-street Station, and it is believed that the alterations have had the effect of putting an end to the annoyance complained of. The exceptional expenses incurred in the actions, and by the consequent change of machinery have been charged to revenue.

Certain negotiations have been in progress between the Directors and holders of Founders' shares with a view to the consolidation of interests, but no definite arrangement has been arrived at. In November, in accordance with the intimation given in the report of last year, a further issue of £20,000 Debenture Stock was made to the shareholders at 2½ per cent. premium, making a total of £50,000 already issued.

The net earnings of the Company during the past year have amounted to £14,580. 7s. 9d. Of this sum £5,498 was distributed in July last in payment of the interim dividend for the half-year ended June 30th, on the Ordinary shares, and 7 per cent. on the Preference shares. The balance of £9,082. 7s. 9d., together with £95. 3s. 7d. brought forward, leaves £9,177. 11s. 4d. now to be dealt with. The Directors propose to divide as follows:—

Dividend at the rate of 7 per cent. on the Preference shares for second half-year	£3,500	0	0
Dividend at the rate of 10½ per cent. for the second half-year on the Ordinary shares, making with the interim dividend 7½ for the year	5,244	15	0
Dividend of £2 19s. 6d. per share on the Founders' shares	297	10	0
Carried forward to Ordinary shareholders' undivided profit account	134	13	3
Carried forward to Founders' undivided profit account	13	1	
	£9,177	11	4

Mr. Walter Leaf and Mr. Bennett Fitch offer themselves for re-election as Directors, and Messrs. Deloitte, Dever, Griffiths and Co. as Auditors.

Yorkshire House-to-House Electricity Company (Limited).

The following report of the Directors of this Company for the year ended December 31st last will be presented to the ordinary general meeting to be held at the Electric Lighting Station, Whitehall-road, Leeds, on Tuesday next, at 2.30:—

The profit (including £162. 1s. 9d. brought forward) amounts to £6,483. 3s. 11d., which the Directors propose shall be appropriated as follows:—To reserve, for general purposes, £2,000; for depreciation, £1,300; payment of interim dividend at the rate of 4 per cent. per annum on the Ordinary shares for the half-year to June, 1895, £1,000; payment of final dividend at 6 per cent. for the half-year to December 31st (making 5 per cent. for the year), £1,500; payment of dividend at the rate of 5 per cent. on 18,948 shares on the amount called and paid up thereon from the respective times of payment to December 31, 1895, £165. 7s. 7d.; balance to carry forward, £517. 16s. 4d.; total, £6,483. 3s. 11d.

The works and plant of the Company have been maintained in an efficient state, and the quality of the supply of electrical energy continues to gives satisfaction. The number of lamps connected to the mains increased during the year from the equivalent of 19,858 to the equivalent of 32,539 35-watt lamps. A reduced scale of charges for current, at a maximum price of 6d. per unit, was brought into operation on July 1st last. The Leeds Corporation, in the last session of Parliament, introduced a Bill authorising them to construct and work electric or other tramways, which affected the Company's interests, and the Directors obtained the insertion of a clause in the Bill, by which the rights of the Company are protected. The Company's mains have been extended to Chapeltown, which has resulted in an encouraging demand for current. It having become apparent that the plant in operation will not suffice to meet the requirements for the winter of 1896, the Directors have decided upon an important extension of the Company's works, and arrangements are being made to carry out that object. In order to obtain the necessary capital, the remainder of the authorised capital, consisting of 9,900 Ordinary shares, was offered to the existing Ordinary shareholders *pro rata* to their previous holdings, and 8,848 shares were taken up.

Mr. Grosvenor Talbot and Mr. Robert Hudson offer themselves for re-election as Directors, and Mr. J. Gordon, Jun., as auditor.

Digitized by Google

Anglo-American Telegraph Company (Limited).

The report of the Directors of this Company, to be presented at the ordinary general half-yearly meeting, to be held at Winchester House, Old Broad-street, London, on Friday next, at 2 o'clock, states that the total receipts from July 1st to December 31st last, including balance of £831. 2s. 7d. brought forward, amounted to £165,589. 11s., an increase of £15,764 compared with the corresponding period of last year. The total expenses of the half-year, including the repair of cables, &c., amounted to £54,795. 10s. 1d., a decrease of £1,056. 8s. 4d.

The Directors have, before declaring the net profits, set apart the sum of £12,000 to the Renewal Fund, leaving a balance to be dealt with of £93,794. 0s. 11d.

Interim quarterly dividends of 10s. per cent. on the Ordinary stock, and £1 per cent. on the Preferred stock, were paid on November 1st last, absorbing £35,000, leaving a balance of £63,794. 0s. 11d, out of which the Directors recommend the proprietors to declare final dividends of 18s. per cent. on the Ordinary stock and £1. 16s. per cent. on the Preferred stock, amounting to £63,000, making a total distribution for the year ended December 31st of £2. 9s. per cent. on the Ordinary stock, and £4. 18s. per cent. on the Preferred stock, and leaving £794. 0s. 11d. to be carried forward to the next account.

The Company's repairing steamship "Minia" has been employed during the past half-year in the repair of the 1873 cable, broken off the coast of Ireland, and of three cables between Newfoundland, Cape Breton and the United States. She has also been employed by the Direct United States Cable Company for the repair of cables belonging to that Company, the payment for which appears in the Revenue Account.

Proceedings in the French law suit are still pending.

Messrs. Francis A. Bevan and William S. Cunard offer themselves for re-election as Directors, and Messrs. Joshua Dean and John Gane as auditors.

Cambridge Electric Supply Company (Limited).

The Report of the Directors of this Company to December 31st last will be presented to the meeting of shareholders to be held to-day (Friday) at the Company's offices. It states that the prospects of the Company continue to be satisfactory. During the past year there has been added to the Company's mains the equivalent of 3,016 8 c.p. lamps, making the total 14,660. In addition to certain alterations, a new 75-unit dynamo and engine has just been added to the plant, bringing up the total capacity of the station to 525 units. A length of 903 yards of main conduit pipe has been added, making a total of 13,051 yards, whilst another sub-station, fully equipped, has been constructed to supply Trinity College, Trinity-street, Bridge-street, and Sidney-street. At the end of the year, one-third of the total supply was delivered from the sub-stations, resulting in a marked economy in fuel. The number of units supplied during the year has been 150,510, against 112,084, an increase of 38,426, or 35 per cent.

The Company has made a profit on the year's working of £1,489. 8s. 10d., which, added to £19. 12s. 2d. brought forward, leaves £1,509. 7s., and after paying £48. 11s. 11d. interest on debenture capital there remains a balance of £1,460. 15s. 1d., and the Directors recommend the payment of a dividend of 3½ per cent., absorbing £1,126. 17s. 11d., leaving £333. 17s. 2d. for depreciation and carrying forward.

NEW COMPANIES, STATUTORY RETURNS, &c.

ARMSTRONG POZZUOLI COMPANY (LIMITED).—This Company was registered on January 23rd, with a capital of £185,000, in £10 shares, to acquire the Italian branch of Sir W. G. Armstrong, Mitchell and Co. (Limited), to enter into an agreement for this purpose, and to carry on the business of hydraulic, electrical and general engineers, ordnance and torpedo manufacturers, &c.

ELECTRICAL APPLIANCES SYNDICATE (LIMITED).—This Company was registered on January 23rd with a nominal capital of £2,000, in £1 shares, to acquire any patents, patent rights, secret processes, inventions, trade marks, or other privileges in connection with electrical appliances, to sell, use, develop, or otherwise turn to account the same, and to erect and construct all necessary machinery and apparatus, workshops and other factories, telegraph, telephone and electric light and transmission wires and lines. The first subscribers are J. T. Hamilton, R. R. Morris and W. F. Hamilton (200 shares each), and James G. W. Aldridge, engineer, K. G. Metcalfe, H. Knight and D. Davies (one share each).

"KUMA" (LIMITED).—This Company was registered on January 22nd, with a capital of £10,000, in 5,000 Fifteen per Cent. Cumulative Preference and 5,000 Ordinary shares of £1 each, to acquire any patents or patent rights relating to the manufacture of a plastic material known as "Kuma," to enter into an agreement with P. W. Wierdsma and J. Kuipers, and to carry on the business of manufacturers of and dealers in plastic materials, chemicals, &c., engineers, electricians, electric supply contractors, metallurgists, &c.

PACIFIC AND EUROPEAN TELEGRAPH COMPANY (LIMITED).—The annual return to December 25th has just been filed. The whole nominal capital of £100,000, in £10 shares, has been subscribed, and a call of £4 per share has been made and paid.

PHŒBUS ELECTRIC BATTERY SYNDICATE (LIMITED).—The statutory return to December 12th has been filed. The nominal capital is £3,000, in £1 shares; 492 of these have been taken up, and the full amount per share has been paid.

PIONEER ELECTRIC CARRIAGE COMPANY (LIMITED).—The annual return to January 2nd has been filed; 64 shares have been subscribed for out of a capital of £20,000 in £50 shares, and the full amount has been called.

PORTABLE ELECTRIC LAMP COMPANY (LIMITED).—The statutory return to January 10th has been filed. The nominal capital is £50,000, in £1 shares. Only seven shares have been subscribed for, and the full amount has been paid thereon.

CITY NOTES.

MEMORANDA.—Bank rate, 2 per cent. (Feb. 22, 1894). Price of silver, 30⅜d. per oz. (Jan. 30th). Consols (2¾ per cent.) 107¼—108 for money, 107⅞—108 for account; 2½ per cent. 104½—104⅝ (Jan. 30th). Stock Exchange Settling Days: Consols, Feb. 3rd; Stocks and Shares Continuation Day, Feb. 11th; Ticket Day, Feb. 12th; Pay Day, Feb. 13th; Mining Share Carry-over Day, Feb. 10th.

BRIGHTON AND ROTTINGDEAN SEASHORE ELECTRIC TRAMROAD COMPANY (LIMITED).—At a recent meeting of this Company the Bill for extending the time for completing the line, and a resolution in favour of raising additional capital, were approved. The chairman said he believed the line would be open for traffic at Whitsuntide.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended January 26th amounted to £994, against £998 in the corresponding week of 1895, a decrease of £4. The total receipts for the half year are £4,035, against £3,999 for the corresponding period of 1895, an increase of £35.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The Directors of this Company recommend a dividend on the Ordinary shares at the rate of 8 per cent. per annum, free of income tax, for the half-year ended December 31st.

ELECTRIC TRACTION ON RAILWAYS.—Mr. John Bell, presiding at the meeting, on the 24th inst., of the Metropolitan Railway Company, stated, in submitting to the shareholders the various objects sought by the Bill which the Company has deposited in Parliament for next Session, that certain properties had been scheduled with the view of improving the ventilation of the line. It was a curious fact that on the subject of ventilation every one seemed to have a theory, but if the Company had tried on their railway one tithe of the experiments or theories for improving the ventilation, the shareholders would have received no dividend that day, and probably the atmosphere of the tunnel would not have been improved to any appreciable degree. They had always regarded electric traction with a longing eye. He had been twice to America—once at his own expense—with a view to seeing whether there was not some development of it which would be worthy of their trial, at all events, but he had found that there was nothing which could by any possibility be made capable of hauling trains of the capacity and weight of those run on the Metropolitan Railway. Up to the present they had found no one able to demonstrate satisfactorily that electric traction could be provided to meet the Company's requirements at the same cost as steam haulage. Still, it was their hope in the future. Daily developments of this wonderful power was being made, and at the present moment they were in communication with an electric supply company, who thought they saw their way to overcoming the difficulty which had hitherto prevailed. He need hardly say that the directors would welcome any success in that direction. While, however, they had been waiting for electricity as hauling power, they had not been unmindful of their duties to the public. Much had been done to secure a purer atmosphere, but they would like to do more, and it was with that object that they proposed to ask Parliament to sanction the purchase of the properties in question.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended 26th inst. amounted to £1,043. The amount for the corresponding week last year was £943; increase, £100.

SCHUCKERT AND CO., NUREMBURG.—This Company is calling in for February 7th an extraordinary meeting of shareholders for the purposes of resolving upon the proposed increase of the capital by £300,000. The Company explains that the continuous growth of the business necessitates the building of further workshops, for which the funds in hand are not sufficient. More facility is especially wanted in the departments for traction work, search-light apparatus, chemical testing, &c. It is proposed to issue 6,000 shares of £50 each.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee has appointed Wednesday, February 5th, as a special settling day in the Provisional Certificates of the further issue of £100,000 Five per Cent. Debenture stock of the City of London Electric Lighting Company (Limited). An application has also been made to the Committee to appoint a settling day in and to grant a quotation for £105,000 Four and a-Half per Cent. Second Debenture stock of the Brush Electrical Engineering Company (Limited).

ST. JAMES' AND PALL MALL ELECTRIC LIGHT COMPANY (LIMITED).—The share transfer book of this Company will be closed from January 27th to February 10th inclusive, preparatory to payment of half-yearly dividends to December 31st last.

SUBMARINE CABLES TRUST.—Notice is given that on and after the 1st February the sum of £1 5s., balance of the coupon due October 15, 1895, will be paid by Messrs. Glynn, Mills and Co., 59, Lombard-street, E.C. Coupons should be left four clear days for examination.

VENEZUELA TELEPHONE AND ELECTRICAL APPLIANCES COMPANY (LIMITED).—Coupon No. 11 of the 5 per cent. First Mortgage Debenture, due 31st inst., will be paid at the Consolidated Bank, Threadneedle-street, London, E.C., or at Messrs. Westendop and Co.'s Bank, Amsterdam. Coupons should be left four clear days for examination.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the week ended January 24th, 1896, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,804.

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861–1878.

No. 925. [No. 15. Vol. XXXVI.] FRIDAY, FEBRUARY 7, 1896. PRICE SIXPENCE.

NOTES.

We learn from copious advertisements appearing in various daily papers that the investing public has been called upon to subscribe some £77,000 on behalf of the Town and Village Electric Light and Power Company between 10 a.m. on Wednesday and 4 p.m. yesterday. If the required amount be not obtained, the failure will not be due to adverse criticism by technical journals; since these have had no opportunity of expressing an opinion on the Parfitt series-system of lighting since May last and the opinions then expressed do not figure amongst the many quoted, although room has been found for the valuable testimonial of *The South African Financial Record*. We may say at once that the Parfitt idea of bifurcating the outgoing lead and cross-connecting the bifurcations at intervals is a good one; the system has also been subjected to a lengthy trial under practical conditions, and the electromagnetic switch appears to have come out of it satisfactorily; finally, the granting of American and German patents may fairly be taken as a stronger evidence of novelty than the granting of an English patent, which is practically no evidence at all. On the other hand, now that the Board of Trade limit for low pressure has been raised to 500 volts a village supply on the three-wire system should prove quite as cheap as one on the Parfitt plan, and it would certainly be vastly more convenient. In other words, it is an open question whether, to put the matter in its lowest terms, the Parfitt system is the only one for the purpose in view. But what is the purpose in view? The lighting, apparently, of some of the "992 Urban District Councils, and more than 30,000 parishes, townships, hamlets and places" to be found in England and Wales. In no case where a house-to-house supply on any of the well-tried methods is feasible is it possible to imagine a supply on the Parfitt plan being rationally preferred; it only has advantages in the lighting of scattered districts by overhead wires. There is, it is true, an imposing number of villages to be electrically lighted. But a big field does not necessarily mean a big profit; the soil must be of a certain degree of fertility to be worth cultivating. A special company formed for the special purpose of running a special system in a special field—and as we hold in a specially poor field—does not commend itself to us as containing the elements of a commercial success in this year of grace. The device did not succeed particularly well in the early eighties, and there is no reason why it should succeed better in the late nineties.

In the prospectus of the Town and Village Electric Light and Power Company there is a mention of a gross profit of over 33 per cent. having been made on the operations of the Kingswood plant, this profit being exclusive of any charge for depreciation, repairs, renewals or establishment expenses. This is a peculiar though it may be technically correct way of foreshadowing probable future *nett* profits. But the serious *non sequitur* which follows, whilst it does credit to the ingenuity of the compilers of the advertisement, does not do equal credit to their ratiocinative powers:—"The foregoing practical test proves that the Company will be able to supply the Parfitt system for public and private lighting on advantageous terms to the consumers, and with very profitable results to the shareholders. The Syndicate having demonstrated the foregoing facts and established the commercial value of the invention this Company has now been formed. . . ." Facts, proofs, demonstrations—evidences of *commercial* value! The English dictionary had better be revised at once.

An article by Mr. H. P. Gaze, which will be found in another column, deals with a branch of research which may be of great importance. That paraffin and similar bodies insulate worse at high temperatures was, of course, well known, but the curious properties mentioned by Mr. Gaze have, we believe, been discovered by him. We do not exactly know what temperatures paraffin goes through during its manufacture or purification, but in making condensers the paraffin is generally kept continuously at a high temperature to drive the moisture out of the fibre when the paper is immersed, and in this connection Mr. Gaze's results are worthy of careful consideration. We do not think oil insulation is going to play a great part in the future. Dry paper is the best cheap insulator, and oil or wax merely reduces the insulation. It is only put there to keep out water.

As we recently remarked in a somewhat similar connection, it is a comparatively easy task to make objections and to foretell difficulties when any scheme of a more or less novel character is propounded. At the same time, when the air is full of military and naval novelties, it is as well that the public should not take all of them too seriously. A Mr. C. Scott Snell, for instance, has, in some recent issues of *Invention*, devoted his time and talents to working out a "Cable Defence Scheme." This scheme is as follows: Special 20-knot cruisers fitted with cable-laying apparatus, are to accompany each British squadron when on the warpath, and in this way

Digitized by Google

the commanders of the aforesaid squadrons will be kept in touch with Whitehall; whether to the benefit of our naval operations may be doubted. But the general outline of a scheme of this character is as nothing compared with the carrying out of its details. To fully deal with Mr. SNELL's proposal, and to follow the author through the imaginary naval conflicts he so graphically depicts, would occupy too much of our space. Suffice it to say that while the author is evidently well ahead of the time in his ideas, he is a long way astern of current cable-engineering practice. We hope, however, on behalf of the "eminent manufacturers" that the following specification is not complete. It runs thus:—"The cable to consist of seven No. 22 tinned copper wires, and having No. 20 sheathed steel wires. Diameter 0·45in. Weight per knot 11·4cwt. in air, and 8·75cwt. in salt water. Price £60 per knot, and may be laid and lifted more than once." Mr. SNELL will, we feel sure, unnecessarily add to the difficulties of his scheme if he adheres too strictly to the above specification. In time of war, no doubt, something of the kind proposed by Mr. C. SCOTT SNELL will be done. In fact, it is an open secret that some years ago, when there was a probability of naval operations having to be undertaken by the British Government, it was arranged that the operating squadrons should be attended by cable steamers with a view to connecting them with their base. If the idea is still considered worthy of attention, it would certainly be well for the main details to be worked out by experienced cable and mechanical engineers, and at any rate pigeon-holed by the Admiralty. The job would probably furnish occupation to many able men for some time to come.

STUDENTS of the gas engine who are still puzzling over the many inexplicable points in gas-engine theory will be not a little astonished to hear from Mr. DUGALD CLERK that he propounded a theory so long ago as 1882 which is "now generally accepted." We are naturally inclined to wonder why, if this is the case, there has been so much pother about what goes on in a gas engine between the moment when the charge is fired and the moment when exhaust is completed. Indeed, most of the heavy fighting, if we may so express it, has taken place since 1882; and he would be a rash man who should say that even now the war of words is ended, and an ultimate theory peacefully agreed upon. Without doubt, Mr. DUGALD CLERK's 1882 Paper on "The Theory of the Gas Engine" (*Proc.* Inst. C. E., Vol. LXIX.) was a valuable contribution; and both it and the discussion which ensued did much to clear away many of the erroneous notions which were prevalent at the time, as well as to set the conditions of good gas-engine practice upon a better footing. But the main value of the Paper lay, not so much in its contribution to theory as in its practical bearing. So far as theory went, Mr. CLERK advocated the dissociation hypothesis of retarded combustion, a hypothesis which has always met with stout resistance from some of the ablest authorities. Not even to-day can we say to what extent dissociation plays a part in shaping the indicator diagram and the $\theta\phi$ diagram of a gas engine. The practical importance of compression in a gas-engine cycle is, however, well brought out in the 1882 Paper, and was at the time a valuable lesson to gas-engine makers. Nowadays no one would dream of questioning the value of this operation in a gas engine; but it may not be generally known to what extent modern improvements in gas-engine economy are due to an increase in the compression. The Paper on "Recent Developments in Gas Engines," which Mr. CLERK recently read before the Institution of Civil Engineers, an abstract of which we reprint this week, gives some useful information on this head.

SOME countries pride themselves upon the lightning-like rapidity with which they recognise and adopt improvements. England, on the other hand, has, until quite lately, taken a certain amount of pride in its surly suspicion of novelties. And the two facts taken together would seem to show that when it comes to being proud about anything, one thing will do as well as another. However, without wishing for one moment to cast any serious doubt upon the general principle of super-lengthy consideration, it is impossible not to think that it has been just a little overdone in the matter of the reform of the standard of light. So long ago as 1888, as Mr. DIBDIN tells us in his recent Paper at the Society of Arts, the Board of Trade, the London gas companies, and the London gas authorities "had all joined in one condemnation of the existing candle," and we quite agree with Mr. DIBDIN that in view of this unanimous condemnation by authorities usually conflicting, "an impartial observer would probably have drawn the conclusion that the time was then ripe for a change, and that legislation would follow without delay." Nevertheless, here we are at the beginning of 1896 in much the same position, scientifically speaking, that we were at the end of 1888; and it must be borne in mind that it is not a question of totally abolishing the Parliamentary candle, but merely of finding a more constant exponent of its many virtues than a spermaceti candle $\frac{7}{8}$in. in diameter burning 120 grains per hour (six candles to the pound). The pentane air-gas flame was in favour in 1888 and remains so to-day; the square-millimetre-of-positive-carbon standard being still in difficulties, experimental and natural. Small wonder, then, that the Expert Committee which was appointed in December, 1891, now recommends the adoption for use in gas testing of the Dibdin 10 c.p. pentane-Argand air-gas flame, and suggests that the gas referees should be given a little freedom in future in the matter of adopting and certifying improved standards. If it is to take something like a decade to obtain Parliamentary sanction for the adoption of an improved standard against which to test London gas, a century may very well be consumed in securing anything in the shape of a really radical reform, should such ever be required.

ONE speaker in the discussion on Mr. DIBDIN'S Paper seemed to think that the proposed standard was guaranteed to be constant everywhere, and under all conditions, and referred to its probable behaviour at 7,000ft. above and 3,000ft. below sea level. The 10-candle standard has been conclusively shown to be, as compared with the spermaceti candle, the mirror of constancy within

Digitized by Google

the limits of London atmospheric pressure, temperature, &c. That fact, almost alone, should, one would think, suffice to secure the prompt adoption of this by no means startling innovation.

THE great convenience of a ready quantitative means of detecting the presence of Röntgen rays is apparent to every one. The photographic plate, in addition to being merely qualitative or at any rate directly quantitative, does not possess the merit of being readily and expeditiously applied. A more useful method is described by Prof. J. J. THOMSON in our correspondence column this week, and consists in allowing the rays to fall on an electrified plate. The presence of Röntgen rays dissipates the charge whether it be positive or negative, even when the plate is embedded in a solid dielectric. The inference which Prof. THOMSON draws from this latter fact is startling enough to justify his use of italics, and interesting enough to bear repetition—viz., that "all substances through which the Röntgen rays are passing become for the time conductors of electricity."

A Novel Telephone Subscriber.—When the "St. Paul" went ashore at Long Branch, N.J., a telephone was fitted up inside her and connected to the New York and New Jersey exchange. This is stated to be the first instance on record of a stranded ship becoming a subscriber to a telephone exchange.

Queen's Counsel.—Amongst the last batch of new Q.C.'s we note the name of Mr. R. W. Wallace, for many years standing counsel to the National Telephone Company, a Director of the Kensington and Knightsbridge Electric Lighting Company, and a well-known figure in most electrical patent cases.

Cable Interruptions and Repairs:—

Absorption of Electrical Vibrations by Electrolytes.—No. 22 of the *Communications* from the physical laboratory of the University of Leyden, which recently reached us, contains two Papers by Dr. P. Zeeman. The first of these is on "Measurements Concerning the Absorption of Electrical Vibrations in Electrolytes," and the second treats of "Measurements of the Absorption of Electrical Vibrations in Different Electrolytes." Both of these Papers are reprinted from *Verslagen der Afdeeling Natuurkunde der Kon Akademie.*

The American Institute of Electrical Engineers.—According to the "catalogue of membership" of this Society it comprised on January 1, 1896, 2 honorary members, 305 members, and and 693 associate members, or a grand total of exactly 1,000. The two highly-honoured honorary members are Lord Kelvin and Mr. W. H. Preece. The alphabetical list is followed by one giving the geographical distribution of the members. New York City by itself contains one quarter of the total membership (257) and New York State contains in all 355 members and associates.

The Systems of the Molecules.—At the close of his address, delivered at the dedication of the physical and electrical engineering laboratory of the University of Kansas, Prof. A. A. Michelson drew a comparison between astronomy and the "infinitesimal systems of pigmy stars" of the molecular universe. He concluded with the following declamation:—

"When will the Kepler come to marshal the present ever-increasing array of facts and queries into one great and consistent whole? When will a second Newton appear to solve the riddle of that complex microcosm we call a molecule? This, their problem: to penetrate, as far as it is permitted to human r wonderful ymeason, that sterious whole we call matter, whose solar systules, whose cworems are molelds are atoms."

The Atom and its Charge.—The following letter has been sent by Prof. J. J. Thomson to the *Philosophical Magazine* and is published in the last issue of that journal:—

"I find that the view expressed by me in my Paper 'On the Relation between the Atom and its Charge' (*Philosophical Magazine*, December, 1895, p. 541), that a negatively electrified atom moved more rapidly than a positively electrified one in the same electric field, was arrived at from different reasons by Prof. Schuster, and given by him more than five years ago in the Bakerian Lecture for 1890. I am glad to find that this view is held by so eminent an authority, and regret that I had previously overlooked such strong evidence in its favour. There is another result given in the same Bakerian Lecture, which I ought to have quoted. I allude to Mr. Stanton's interesting experiments on the escape of electricity from a hot copper rod surrounded in one case by oxygen and in another by hydrogen."

The Magnetic Influence of the Planets.—In the meteorological records of the St. Petersburg Academy of Sciences, Vol. XVII., there is an exhaustive discussion of the magnetic observations made at St. Petersburg and Pawlowski from 1878 to 1889, and their bearing on the influence of the various planets on the magnetic declination. From this it would appear that all the planets exercise a marked influence not only on the absolute value of the declination, but also on its diurnal variation. All the planets except Mercury increase when they are near the earth both the absolute value of the declination and the periodic portion of the daily variation. The extreme values of the declination differ in a year by 0'·85. Taking this amplitude as unity, the following numbers express the amplitude of variation corresponding to an entire synodic revolution of the respective planet:—Mercury 0·58, Venus 0·61, Mars 0·59, Jupiter 0·40, Saturn 0·12, Uranus 0·15, Neptune 0·27. ——In the current number of *Nature* there is an interesting article by Prof. A. Schuster, criticising this alleged magnetic influence. Prof. Schuster thinks that "among the many improbabilities of magnetic influences which are hanging over us, that of a planetary effect may for the present be set aside."

The Elektrotechnischer Verein of Berlin.—At the last meeting of this Society, on January 28th, the annual election of officers took place. The elections were, as usual, very quickly got through. The Verein has at present a surplus of £1,350, and Dr. Strecker made the warmly-received proposal not to let the surplus accumulate, but to employ it in a more useful way. For instance, the provision of a free barrel of beer at every meeting of the Society would not be a bad plan. Other proposals were made as to the selection of a more comfortable place of meeting. The surroundings at present always created a feeling of being in a church or a picture gallery. A large number of members were hard at work during the day, and these required a little recreation before going on with more intellectual work. Again, one could not speak well on an empty stomach. The meetings should commence at 8 p.m., instead of 7 p.m. as hitherto. There was a visible tendency at present to shorten the meetings and get away to refresh the inner man.

Expiring Patents.—On Sunday next will expire Patent No. 626, of 1882, granted to A. A. Common for "Improvements in Electric Lamps." The specification describes a non-focussing arc lamp.——On Tuesday, the 11th inst., will expire Patent No. 661, granted to H. H. Eldred and T. B. Doolittle for "Improvements in Telephone Exchange Systems and Apparatus, part of which Improvements is also applicable to other similar purposes." The specification describes a system in which a central exchange is supplemented by a system of sub-exchanges connected by trunk wires.——On Tuesday next will also expire Patent No. 677, granted to W. E. Langdon for "Improvements in Interlocking Electric and other Signalling Apparatus for Railway and other traffic, particularly applicable to existing forms of Electric Railway Signalling Apparatus."——On Tuesday next will also expire Patents Nos. 686-689 granted to G. M. Hopkins for "Improvements in Telephone Call or Signalling Apparatus," &c. The batch of specifications describe a system and details of apparatus for telephonic intercommunication.

Coal Consumption on French Electric Tramways.—Comparative figures of the coal consumed per car-mile run on French tramways, employing different methods of propulsion, are contained in an article on electric lines by E. Cadiat in the *Portefeuille*

Digitized by Google

Economique des Machines. As regards storage battery traction, on the lines from St. Denis to the Madeleine and from the Opera to Neuilly the car-mileage aggregated, in 1893, 502,060, or 1,376 car-miles per day. The steam engines at St. Denis furnished for this service a total of 6,500 H.P. hours, or 4·72 H.P. hours per car-mile. M. Badois, who reported these figures, gives 2·75lb. of coal as the consumption per horse-power hour, and arrives at 12·98lb. of coal per car-mile. At Marseilles, during the first two weeks of operation of the trolley system, 150,348lb. of coal were consumed to run 19,970 car-miles, and during the second two weeks 150,975lb. for 18,983 car-miles. The average is 7·75lb., which, however, includes the coal used in connection with the lighting of the cars and the power station.

Extensive Water-Power Scheme in Canada.—According to the *Electrical Engineer* of New York, "Among the water-power enterprises lately developed in America one of the most noteworthy in many respects is the work of the Keewatin Power Company at the outlet of the Lake of the Woods, Canada. The Company's constructions are expected to supply a minimum of 40,000 H.P. in the driest seasons. The Lake of the Woods covers an area of 3,000 square miles, is fed by the Rainy River and many small streams draining an area of about 30,000 square miles. The ambitious design of converting this great lake into a mill pond, and its outlet into power flumes by an enormous dam across the Winnipeg River, has already been carried to a successful issue. This dam, with its long row of massive granite piers built on the solid rock of the river-bed, is a structure as permanent as the rocky shores of the river. It has been constructed with all the requisites for retaining and regulating the flow of water, and the head maintained for the flumes is about 21ft. The commercial and industrial possibilities of this 40,000 H.P. supplied by Nature in a district surrounded by abundant wooded land, and in the excellent farming country between Winnipeg and Lake Superior, can scarcely be over-estimated. The many inventions which have multiplied the uses of wood fibre will be advantageously turned to practical use in a district where cheap power and an abundance of the pulp woods are found together. The ever-increasing harvests of the North-West will also, in the natural course of events, call for increasing milling capacity, and cheap power will be a material factor in transferring to the Western Continent the work of grinding wheat for the European consumers."

Obituary.—We regret to announce the death of Mr. Augustus Calder, the Metropolitan Manager of the National Telephone Company, which took place at his residence at Wandsworth on Sunday last. Mr. Calder, who was only 42 years of age, entered the service of the National Company almost at the commencement of its existence, and by merit alone speedily improved his position in the Company, until at the time of his death he was the Metropolitan Manager and responsible for the working of the metropolitan exchanges. Mr. Calder took an active part in the recent metallic circuiting of the London telephone system, and contributed much to the success of the work. Deservedly popular with the large staff of the National Company, Mr. Calder will be sadly missed by a large circle of acquaintances. Mr. Calder was married, but leaves no family. Early in December he appears to have contracted a bad cold, and subsequently this developed into rheumatic fever. He was away from business until the beginning of January, and then again caught a severe cold, which developed into pleurisy and pneumonia, from which he died.——We regret to announce the death of Mr. D. K. Clark, which took place at the age of 74, on the 22nd ult. Mr. Clark was well known as the author of several treatises on engineering subjects, and his works on "Tramways: their Construction and Maintenance," "The Steam Engine," and his "Manual of Engineering Rules and Data," are highly valued by engineers. His associations were principally with locomotive practice, on some branches of which he was a distinguished authority; but his literary work showed close acquaintance with a very much wider field of engineering practice.

Electric Railway Supply by the Niagara Falls Power Company.—Our Niagara Falls correspondent sends us the following particulars with regard to the electric supply of the Buffalo and Niagara Falls Electric Railway, the Niagara Falls and Suspension Bridge Railway, and the Whirlpool and Northern Electric Railway, which are all now enjoying a power service from the central station of the Niagara Falls Power Company. In reducing the voltage and changing the current from alternating to direct, a rotary and a pair of static transformers are used. It is a well-known fact that if the armature of any direct-current dynamo be tapped at points which are electrically 180deg. apart, an alternating current can be drawn from this armature. If now the dynamo be run as a motor from the direct-current end, and an alternating current can be drawn from collector rings tapped on at the points above mentioned, and *vice versâ*, if the dynamo be run as a synchronous alternating-current motor a direct current can be taken from the commutators. This last is the principle on which is constructed the 500 H.P. rotary transformer supplying the electric railways around Niagara Falls. The cables from the Power House are connected to the middle points of two double-pole, double-throw switches. Throwing the switches up throws the current into two auxiliary static transformers, the secondaries of which are connected to a quarter-phase starting motor. The armature of this starting motor is on the same shaft as the rotary transformer armature. Then the field circuit of the main armature is closed and voltage allowed to build up. The switches are put down, the current passing through the two static transformers being reduced in voltage by them from 2,250 to about 440. In its passage through the revolving armature the voltage is increased in the ratio of 7 to 10, which makes the final direct-current voltage about 600.

The Alternate-Current Transformer.—In his third Cantor Lecture Dr. Fleming dealt with the testing of transformers. A clear idea of what was meant by magnetic induction was, he said, essential to the proper understanding of the subject. He then gave the following rule, by which, knowing the throw a given quantity of electricity will cause when sent through a ballistic galvanometer of known resistance, and knowing also the number of turns of the coil through which the whole induction (N) is threaded, we can determine N from the galvanometer throw due to the sudden withdrawal of the induction from the coil. The rule is as follows:—Webers × Linkages = Coulombs × Ohms or Microwebers × Linkages = Microcoulombs × Ohms. (1 Weber = 10^8 C.G.S. lines.) The Ewing hysteresimeter was then shown and described, and a table of hysteretic constants (η) for various irons and steels was thrown on the screen. Coming next to the methods of testing transformers, Dr. Fleming expressed his astonishment that so few central station engineers ever took the trouble to test the transformers they purchased, and stated that he should that evening confine his attention to methods which were really practicable in supply stations, workshops and similar places. After alluding to the three-ammeter method, the accuracy of which was, he said, limited by the limited accuracy of the average commercial ammeter, and to the ingenious and useful differential method due to Dr. Sumpner, the lecturer explained in detail a method of testing a transformer with the aid of an auxiliary transformer for keeping the main pressure constant, a transformer for supplying the current to the shunt coil of the wattmeter, a wattmeter, ammeter, voltmeter and non-inductive resistance. An ingenious simplification of this method, in which the wattmeter transformer is dispensed with, was next described. Experiments were then made to exhibit the necessity of constructing alternate-current wattmeters without metal parts, and the lecturer stated that he had found that the fixed thick wire coil, unless properly made, had eddy currents set up in it, which vitiated the results. Dr. Fleming then showed some of his resistance "cages" for dissipating energy, a detailed description of which appears elsewhere in our present issue. Curves were next thrown on the screen, showing the marked effect of temperature on iron core losses, which fall off as the temperature rises, and *vice versâ*; the core loss in the case of a 50-kilowatt transformer was about 10 per cent. less after 18 hours' running than when cold. Core loss was also, he said, greatly influenced by the shape of the wave of primary E.M.F., a peaky wave giving less loss than a flatter wave. The lecture concluded with an experiment showing how bad magnetic leakage in a transformer could be detected by the rotation of a pivoted iron disc held within the region of the stray field.

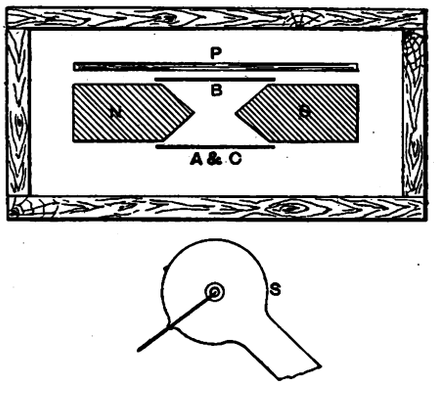
ON THE PRESENT HYPOTHESES CONCERNING THE NATURE OF RÖNTGEN'S RAYS.

BY DR. OLIVER LODGE, F.R.S.

When I wrote the article last week, which you printed on page 438, I was still uncertain whether Röntgen rays might not experience a trace of deflection in a strong magnetic field; and this, notwithstanding the assertion of the discoverer that he had found no deflection. No details of the experiment had been given, and although it might seem safe to trust the bare assertion of so known an experimenter as Prof. Röntgen, yet, on account of the portentous gravity of the issue, I felt bound to satisfy myself by a direct confirmatory experiment. If only there were a magnetic deflection of the rays, the very simplest of all possible hypotheses would be confirmed—the hypothesis, viz., of a kind of sound-pulse conveyed by electrified particles, streaming on the whole in one direction, with interchanges of energy, passing on the motion in a Grotthüs-chain kind of fashion, but passing it on by simple material impact; a kind of electrolytic radiation, as I then expressed it. The details of this hypothesis were given by Prof. Fitzgerald in your columns, Vol. XXXII., p. 573, and Vol. XXXIII., p. 151.

My first experiment on magnetic deflection, the shadow-graph of a magnet with a back-ground of wire-gauze, only showed that if there were any shift by reason of passage of rays between the poles it was very small; but I have now definitely to assert that a further experiment has been made which effectually removes the idea of deflectibility from my mind, and confirms the statement of Prof. Röntgen.



Experiment on Magnetic Deflectibility. S = Source of Radiation with Spherical Cathode. P = Sensitive Plate. N.S. Magnetic Poles; A, B, C, are wires of which A and C are one above the other, about half an inch apart so that the shadow of B lies between them. Wooden box ¼-inch thick.

A strong though small electromagnet, with concentrated field, had a photograph of its pole-pieces taken, with a couple of wires, A and C, stretched across them on the further side from the plate—nearer the source—and a third wire B also stretched across them, but on the side close to the plate (see Figure). These three wires left shadows on the plate, of which B was sharp and definite, while A and C were blurred.

A couple of radiographs were taken by Mr. Robinson, one with the magnet on, and one with the magnet reversed. On subsequently superposing the two plates, with the sharp shadows of B coincident, the very slightest displacement of shadows A and C could have been observed, although those shadows were not sharp. But there was absolutely no perceptible displacement, the fit was perfect. Consequently the hypothesis of a stream of electrified particles is definitely disproved; as no doubt had already been effectively done in reality by Prof. Röntgen himself.

But it must be noted that the hypothesis of a simple molecular stream—not an electrified one—remains a possibility. The only question is whether such an unelectrified bombardment would be able to produce the observed effects. In so far as it could affect photographic plates one would suppose it must be by means of phosphorescence, but it is doubtful whether it would even have the power of exciting phosphorescence.

It must be remembered that Dr. Lenard found among his rays two classes as regards deflectibility—some much deflected, others less deflected;—and it must be clearly understood that his deflections were observed, not in the originating vacuum tube, where the fact of deflection is a commonplace, but outside, after the rays had been as it were "filtered" through an aluminium window. He did not, indeed, observe the deflection in air of ordinary density, it was in moderately rarified air that he observed it, but he showed that the variation of air density did not affect the amount but only the clearness of the minimum magnetic deflection. The circumstance that affected the *amount* of the deflection was a variation in the contents of the originating or high-vacuum tube.

The hypothesis, therefore, that naturally suggests itself is that the highly-charged particles flying from the cathode deliver up the greater part of their charges when they reach the aluminium window, and that the outside particles which take up the running are less charged, some of them perhaps not charged at all. These last would not be so likely to excite phosphorescence, hence Lenard would not perceive them; he would only observe those that had managed to retain or acquire a modicum of charge, and these would be deflected.

The question has still to be asked, therefore, whether the rays discovered by Prof. Röntgen, which are not at all deflected, are those which possess no trace of charge.

Besides, it must be remembered that the absence of deflection has only been proved in ordinary air, while the presence of magnetic deflection has only been proved in somewhat rarefied air; the investigation into this matter is not finished until a further experiment is done—viz., to verify the non-deflectibility of the Röntgen rays even in a fairly good vacuum.

So much for what remains of the almost defunct radiant-matter hypothesis (defunct only, be it understood, for the particular kind of rays studied by Prof. Röntgen; and not really defunct for them, but in a state of suspended animation. The hypothesis of a bombardment of uncharged particles I have by no means yet abandoned).

The alternative hypothesis, as generally conceived, is some form of waves. True, no absolute necessity has been yet made out for a periodic disturbance travelling at a finite speed; but the circumstance that fluorescent materials are excited, and chemical action precipitated, suggests a periodic motion not altogether out of time with the vibration-frequency of molecules.

Let us grant, then, that this circumstance renders it likely that the cause of the Röntgen effects is to be sought in some kind of wave-disturbance in the ether. The next question that arises is, Is it of the nature of etherial *light* or of etherial *sound*? Is it such transverse or electrical vibrations as are obedient to the equations of Maxwell, or is it a mode of longitudinal disturbance requiring some generalisation or modification of those equations in order to express it?

On the principle that we are bound to apply the simplest hypothesis until it can be shown to be insufficient, it is necessary to consider how far the hypothesis of transverse or electrical vibrations can be made to serve. The chief difficulty here is the transparency of electrical *conductors*. To Maxwell's waves, *i.e.*, to *light* of every kind, they ought to be opaque. But already the translucency of gold leaf has been a slight known difficulty in the same direction, and it has been shown that by postulating interstices or lack of homogenity, *i.e.*, a structure not infinitely fine-grained with respect to the size of light waves, the difficulty can be more or less satisfactorily overcome. Why not, then, assume that these new waves are much smaller than any hitherto known? Why not assume that they compare closely in size with the atoms themselves? Indeed, if they compare in frequency, they *must* compare also in size if they are transverse waves, for the only pace at which such waves can travel through the ether is accurately known. That there is plenty to be said for this hypothesis is obvious from the fact that it appears to commend itself both to Prof. Schuster and to Prof. Fitzgerald. Among other things that can be said in favour of it are the following. Electrical oscillations in conductors are known to have the power of exciting light-waves, hence light-waves may be expected from electric oscillations or surgings in atoms; but visible waves are not so

Digitized by Google

excited. Visible light appears to be due to something more like the sound-vibration of atoms, as if they were bells or plates struck and made to vibrate. Bells and plates of atomic size would vibrate at about the required pace, viz., 400 to 800 million vibrations per second.

But electrical or Hertz-like oscillations of a charge on conductors of atomic size would vibrate immensely faster, being controlled not by the rate at which *sound* travels across an atom, but by the rate at which *light* travels, and this is just about 100,000 times as quick. Hence, as has often been pointed out, electrical oscillations in atoms are too quick for light; but yet they must occur, one would think, when atoms are being violently disturbed and charged and discharged; and if ever such oscillations occur, transverse waves must be emitted. Why should not these constitute the Röntgen rays?

This matter of the extra-rapid ultra-ultra-violet light may be safely left in the hands of its supporters. Its great advantage is that it utilises no new or unknown property of the ether—nay, more, it utilises a disturbance which, although not yet otherwise discovered, must naturally be assumed to exist, unless definite reason is shown against it. It is needless to emphasise further the high probabilities in favour of this hypothesis. Such statements as there are against it will follow incidentally.

Now we come to the last hypothesis, the one suggested by Prof. Röntgen—the one which, judging from page 447 of your last issue, commands the high support of Prof. Boltzmann,—the one which it is not too rash to assume is regarded not unfavourably by Lord Kelvin,*—viz., the hypothesis of etherial sound or longitudinal waves in the ether. The only facts hitherto assumed to utilise longitudinal or pull-and-push properties in the ether are the facts of gravitation and of cohesion. Newton himself showed that an etherial tension or pressure would account for gravitation. Nothing is known about these properties, and there are difficulties in supposing that the ultimate space-filling medium can be really compressible. It is not, indeed, necessarily compressible to account for cohesion and gravitation, but it must either be compressible, or else simulate the effects of compressibility, if it is to transmit a periodic or atom-shaking disturbance at any finite pace.

Assume for the moment a slight compressibility of some sort, and consider what occurrences there are in a well-exhausted vacuum tube which could start longitudinal waves in such a medium. We have in the vacuum tube a violent torrent of atoms striking on the glass. Suppose that the vacuum is about 10^{-6} of an atmosphere—which appears to be something like that needed to give good effects—then the distance apart of the residual atoms in the exhausted space is a hundred times as great as in ordinary air, and a thousand times as great as in liquids; hence the distance will be about 10^{-5}cm.; or each spot of glass will receive a hundred-thousand blows from every centimetre length of the stream to which it is subjected. But the speed of the cathode rays has been directly measured by J. J. Thomson as something comparable to 10^{7}cm. per second. Hence the glass will be struck on the average, at every point, 10^{12} or a billion times a second, by the mere procession of negatively-charged atoms. It is easy for this estimate to err by a factor 10, and it is also easy for places to be sometimes struck ten times more frequently, by reason of the above estimate being only an average. Hence it may be surmised that the frequency of luminous vibrations are occasionally reached, and the glass not only grows hot but also shines.

It is probably quite unnecessary to appeal to this rapidity of bombardment in order to account for visible fluorescence, but the rapidity of bombardment is of interest because in any compressible medium such rudely periodic disturbances could hardly help starting some kind of sound waves.

But, besides that, the atoms themselves are known to be elastic, and to have definite periods of vibration like plates or bells, as evidenced by their spectroscopic lines; hence the blows to which they are subjected must be thought of as likely to excite vibrations or crispations in them. The frequency of these are such as to emit luminous waves in an ether possessing electromagnetic properties, the atoms being charged; but if they occur in an ether which is anything like a compressible fluid, how can they avoid exciting mechanical or sound waves too?

Nothing can be known for certain about the wave-length or velocity of such waves in ether until an interference or diffraction experiment has been performed, but the order of magnitude of the frequency can be taken as that of light, say 10^{15} per second, or quicker. The only way at present to gather some idea of the wave length is to attend, (*a*) to the sharpness of the shadows, (*b*) to the thickness of medium which is effectively opaque.

The longer the wave the more transparent are things likely to be, because waves are always damped out logarithmically, and this needs a certain number of swings, or at least a certain fraction of a swing, for notable damping to occur. A wave a yard long is not likely to be effectively stopped by an obstacle an inch thick. Without a knowledge of the damping-ratio, however, no numerical estimate can so be made, but a better estimate can be got from the sharpness of shadows. Take a point source, and investigate the outline of the shadow of an object held at a moderate distance from the screen or sensitive plate. No clear shadow will be thrown when the size of the obstacle is comparable to a wave length, if its size is small, or when it is removed several wave lengths from the plate, if the size of the obstacle is large. For, in wave theory, shadows are thrown by interference; and diffraction effects become prominent even when a want of precision about the source hinders the recognition of any clear diffraction pattern. The latter would not only indicate the wave length, but measure it. Short of that an estimate can be hoped for. Mr. A. W. Porter, in Prof. Carey Foster's laboratory, has obtained the sharpest radiographs I have yet seen, and he has the best chance of getting the data for an estimate. Suppose for the moment we guess that a wave length of about 1cm. is not unlikely, then the speed of the hypothetical longitudinal waves would be of the order 10^{15}cm. per second, or more, *i.e.*, about as much quicker than light as light is quicker than sound.

Such waves if they existed might be reasonably styled gravitational waves; for although gravitation does not need any wave propagation, only a state of statical stress or tension, yet it would be the rate at which the tension travelled outwards if a fresh piece of matter started existence, or probably if an old piece of matter moved about with sufficient rapidity. Such motion would appear likely to entail aberrational effects, but aberrational questions are notoriously difficult, and the subject is only here mentioned because it is doubtful whether the Laplacian difficulty would be felt in astronomy if gravitation travelled a million times as quick as light. The pull of the sun would be felt in the time that light needs to travel 92 miles, and this is nearly instantaneous; or, otherwise, the terrestrial aberration-angle for gravity would be only the hundred-thousandth part of a second of arc.

But what about the Cavendish-Faraday-Maxwell experiment? that experiment which is held to establish the incompressibility of the ether, or the electrostatic law of inverse square, or the impossibility of a free or isolated electric charge (*see* "Modern Views of Electricity," Second Edition, pp. 9, 11, 29, 31-34, 257). We cannot tell what the volume-elasticity of the ether has to be, in order to transmit condensational waves of the above speed, unless we know its density. Dr. Larmor has shown some reason for supposing that ether may be as dense as platinum. If it be anything like that, and if the longitudinal wave velocity is 10^{15}, then the incompressibility is more than 10^{30} C.G.S. units; too great for any such experiment to show.

The object of mentioning these matters here is to help to realise that there is nothing in present knowledge obviously fatal to the idea of longitudinal waves in the ether; but the arguments in their favour, in connection with Röntgen rays, remain to be given. Assuming wave propagation of some kind, every argument against tranverse is in favour of longitudinal, and *vice versâ*.

* In this connection it is interesting to refer to Lord Kelvin's Presidential Address to the Royal Society, November 30, 1893 (Harrison & Son, London), on the subjects of Hertz-waves and Radiant Matter, in which he confidently anticipates further progress and gives an interesting *résumé* of the history of highly exhausted vacuum-tube effects in connection with that subject. He emphasizes the important part played by Cromwell Varley in 1871, before either Hittorf or Crookes, in the discovery of cathode rays, and strongly supports the material view, in opposition to many Continental workers.

Digitized by Google

Now the thing that suggested longitudinal waves to Röntgen was the fact that crystalline properties were of no importance: *e.g.* that Iceland spar and quartz were equally transparent or opaque whichever way you turn them. But it must be admitted that such a test as that is next door to none. If *tourmaline* is transparent to Röntgen rays going along its axis it would be a much better test; and this I have myself ascertained to be the fact. J. J. Thomson also has found that a pair of ordinary cut tourmalines are equally transparent whether their axes are "crossed" or parallel; which is an excellent test. Nothing suggestive of polarisation in any form has yet been observed; a fact which tends against transverse and in favour of longitudinal waves. But the strongest argument in favour of longitudinal waves is derivable from the fact that the rays discharge electrified bodies. Lenard found this, and J. J. Thomson and I have both obtained it easily under Röntgen-like conditions; but their peculiarity is that (unlike light) they discharge positive and negative about equally.

Now, Elster and Geitel showed that when polarised light discharges a really smooth surface it is most effective when the electric oscillation is partly normal, not tangential, to the surface; in other words, that it is what may be called the longitudinal or end-on component of ordinary light that is by far the most effective in discharging electricity.

Mr. Robinson thinks he has observed that the same thing is true as regards the power of exciting fluorescence: an important observation if true, but the examination is not complete yet. If it turns out so, then the two things that Röntgen rays are known to do are characteristic of end-on or normal vibrations.

As to the photographic or *radiographic* action, it is so slow and inadequate at present that it hardly looks like a direct primary effect but even there it seems as if thick films did better than thin.

Another fact that gives a gravitational look to Röntgen's rays is the fact that they appear to pay more attention to specific gravity or ordinary density than to any other property of matter. This can be said without stating that opacity and density are strictly proportional. Any way, electrical properties of matter seem to be quite unimportant; polish or roughness, a coherent block or a powdered mass, are all the same to these waves, as they are to gravity.

Direction of crystallisation matters nothing, nor does shape; an aluminium prism cannot bend them; they cannot be bent or even reflected to any considerable extent. If it be found that physical state is also unimportant, so that the same molecules obstruct equally however they be aggregated, whether into solid, liquid or gas, that will be a further contribution to the evidence in the same direction.

Thus there is plenty of scope for experiment. A few weeks may be sufficient to intensify our conviction in one or other of the already-mentioned directions, or we may find ourselves urged by new facts in some other direction not yet thought of.

In conclusion, let it be remembered that Lenard, Hertz, Goldstein and the Germans generally (except Helmholtz—a notable exception!) have consistently urged that cathode rays were something more than a stream of particles; in case it should so turn out, Lenard urged this for his rays outside, in air, Hertz, I believe, urged it for the rays inside the vacuum. It may be that the streaming particles are there, but an ethereal process may be also there. Outside in the Lenard rays both processes possibly coexist, one deflectible by a magnet, the other not. That both processes exist also inside the vacuum is not likely. J. J. Thomson has exposed a protected plate in the very rays themselves inside the vacuum and got no result. It looks as if the streaming particles alone could not achieve it.

If the sun emits any rays that can reach photographic plates through boxes or hand bags, even through black paper, every touring photographer should know; but if cathode rays alone have no direct action, without the intervention of a phosphorescent substance, then even the absence of direct solar action would constitute no valid and conclusive proof that the coronal rays are not electrical, though it would very much militate against a method of easily obtaining a photographic record of the corona which has been suggested.

Liverpool, February 2, 1896.

THE EFFECT OF TEMPERATURE ON THE RESISTANCE OF PARAFFIN AND RESIN OIL.

BY H. P. GAZE.

Although it is many years since the use of mineral and vegetable oils for insulating purposes was suggested by Prof. Hughes, it is remarkable how little research on this subject has been carried out, or at any rate published. With the exception of a few indefinite tests mentioned in the *Proceedings* of the Institution of Electrical Engineers for March, 1892, in the discussion on Prof. Hughes' Paper on "Oil as an Insulator," and a series of tests on vacuum and on pure oils

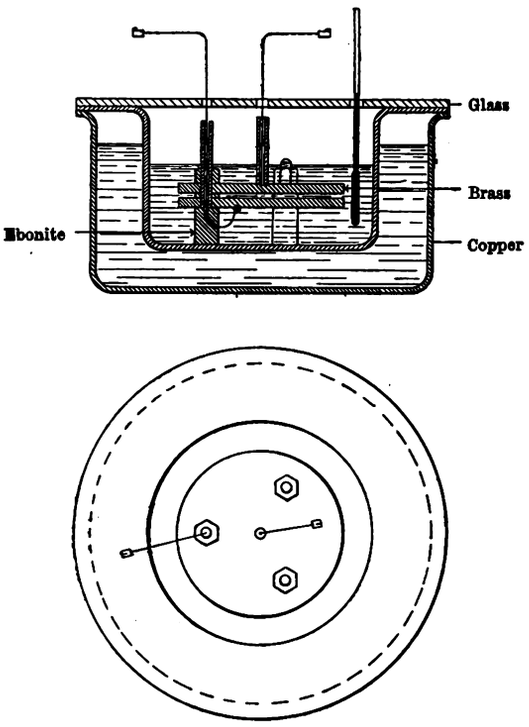


Fig. 1.

in Messrs. Bedell and Kinsleys' Paper on the "Residual Charges of Condensers," there appear to be no accessible results of experimental work on this subject; yet the growing use of oil insulation in electrical apparatus, such as transformers and condensers, renders a close knowledge of the behaviour of oils under varying temperatures of great interest and commercial importance.

The present investigation was confined to the behaviour of paraffin and resin oil, at various temperatures within the ranges met with in commercial apparatus. The apparatus

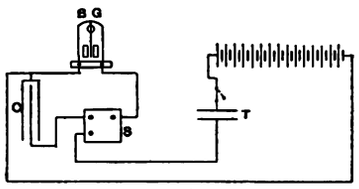

Fig. 2.—Diagram of Connections.
C=Muirhead Standard Condenser. S=Two-way Paraffin Block-key.
T=Sample under test. B G=Ballistic Galvanometer.

used consisted of a copper bath, containing the substance under test, the temperature of which could be varied and controlled by its immersion in a second bath filled with the same substance and heated externally, a steady and gradual rise of temperature of the internal bath being thus obtainable. In the inner bath were supported two circular brass plates of equal area, kept at a distance of 1mm. from each other by three small ebonite distance pieces, the whole being insulated from the bath by substantial ebonite feet (Fig. 1). To avoid any risk of impurities passing over from the outer to the inner bath, the same substance was used in each.

Digitized by Google

The method of test (Fig. 2) was to charge the condenser through the substance tested for 60sec. and discharge through the ballistic galvanometer. The E.M.F. used was from 110 to 120 volts.

The insulation of the apparatus was thoroughly tested over the whole range of temperature employed and found practically perfect. The paraffin used was the ordinary white commercial paraffin wax.

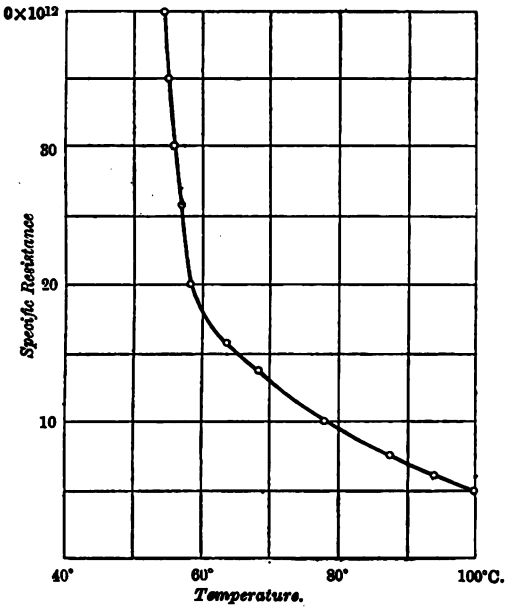

FIG. 3.

Though the apparatus used was not sufficiently sensitive to find the value of the specific resistance at normal temperature, it was found to be not less than 10^{18} ohms.

A series of tests was taken with rising temperature up to 55°C., the temperature of solidification of paraffin, and no

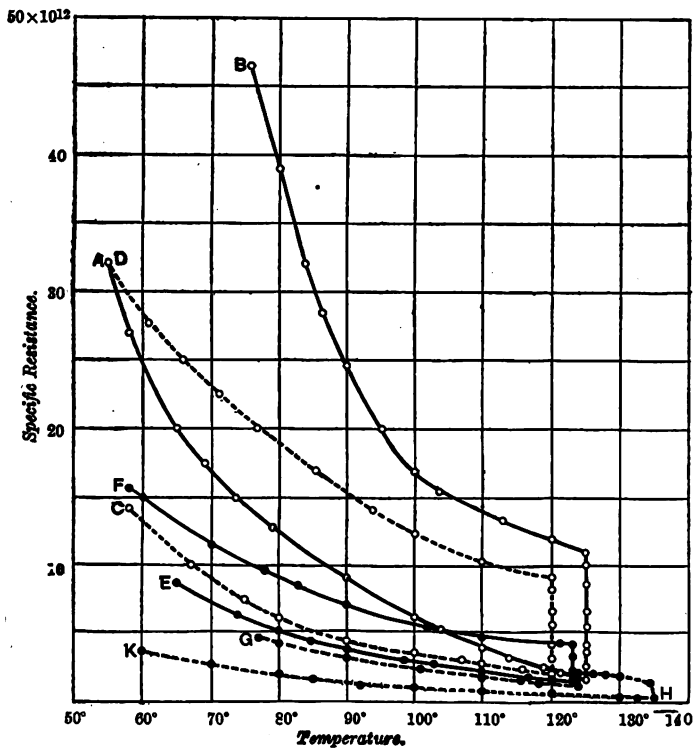

FIG. 4.—Test I., from A along —— line to B.
Test II., „ C „ ..... „ D.
Test III., „ E „ —— „ F.
Test IV., „ G „ .. ... „ H and back to K.
Paraffin cooled solid after each test.

appreciable change in the resistance was observed, but at this point the resistance fell suddenly to 4×10^{13} ohms; after this the fall of resistance up to 120deg. was steady and the resistance was constant at any one temperature, the curve Fig. 3 showing the fall of resistance from 55°C. to 100°C.

At 120deg. to 123deg. a curious *rise* of resistance with time took place, the insulation improving steadily for about an hour and then apparently attaining a steady value. On cooling the values of the resistance on the cooling curve were all much higher than on the curve of rising temperature. When cold the resistance of the paraffin was too high for measurement.

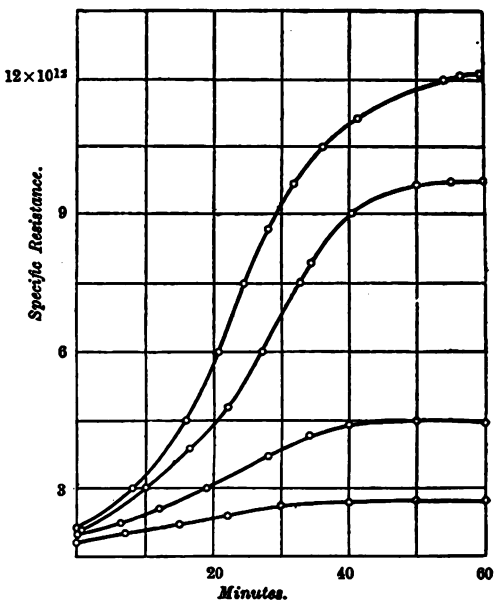

FIG. 5.

The test was repeated on four successive days, with the same sample, and, as will be seen, the phenomenon was repeated on each occasion, although the values were lower on each successive cycle, Fig. 4 showing the four series obtained.

The resistance at the commencement of the improvement on each cycle was fairly constant at about 2×10^{12} ohms. The curves in Fig. 5 give the extent of the improvement on each test, and show very clearly the gradual diminution in the improvement after repeated heatings, until on the fourth day the improvement is very small at the critical point and the values low all along the curve.

After the small improvement of the fourth test, the temperature was again raised, and the resistance was found to be fairly

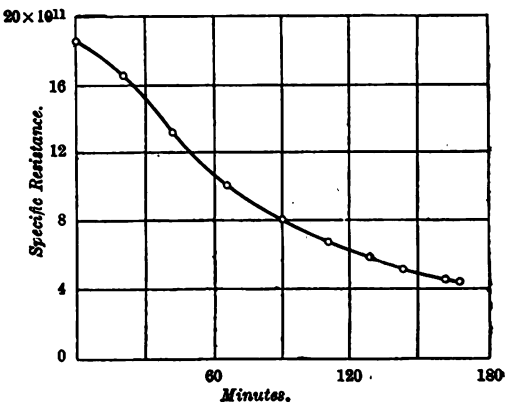

FIG. 6.

constant at each temperature up to about 135deg. Here the insulation deteriorated steadily with time and showed no signs of attaining a minimum value, the curve Fig. 6 showing the rate of deterioration with time. On cooling solid, the paraffin was now evidently permanently damaged, having a specific resistance of $6{\cdot}5 \times 10^{14}$, enormously less than that of the original substance; the wax was also slightly discoloured, being tinged with yellow.

A further test on a fresh sample of paraffin was also taken, the temperature being quickly raised to a high value, about 170°C. The deterioration with time was much more rapid, the

Digitized by Google

resistance being reduced in 25min. from 5×10^{12} to $1{\cdot}6 \times 10^{12}$ ohms. On cooling solid the paraffin was permanently damaged, being of a pale yellow colour, and having a specific resistance of $1{\cdot}6 \times 10^{15}$ ohms.

Finally, a test of six hours' duration was taken on a fresh sample, the temperature being kept constant at 123deg., the critical point to be investigated. The curve obtained (Fig. 7) shows that the improvement is only of a temporary character, being complete after about an hour's time; the resistance then gradually fell again, having only fallen to its initial value at the temperature even after six hours, showing the extremely slow rate at which the substance decomposes at this temperature.

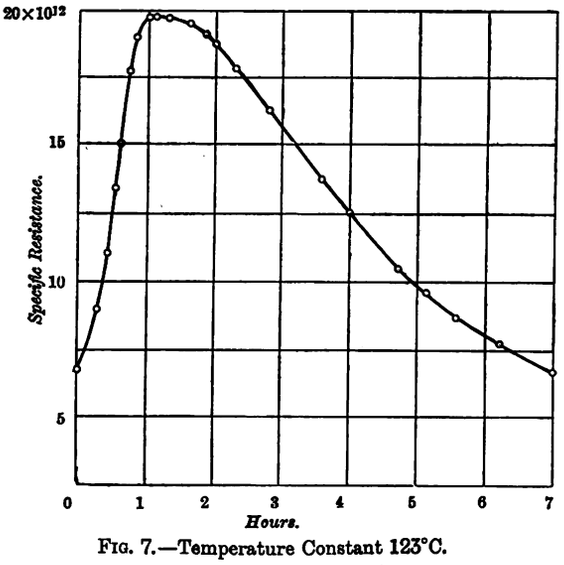

FIG. 7.—Temperature Constant 123°C.

It was at first thought that the improvement observed might be due to the distillation of volatile impurities. To test this theory a fresh sample was heated in a retort at a temperature of 123deg. for more than three hours, but there was no appearance of any distillate in the condenser.

The explanation of these phenomena seems to be that at about 125°C. a molecular change takes place in the paraffin, which is complete at the end of about 60min., the resulting substance then having a very considerably increased resistance;

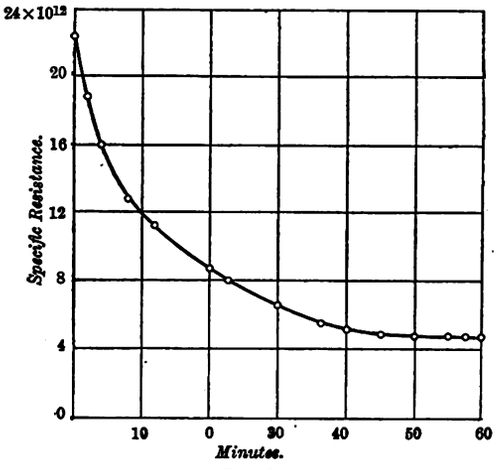

FIG. 8.

but, simultaneously with this action, there is also a slow decomposition or resinization, which shows no signs of ceasing after six hours' continuous heating, the resistance in this space of time having fallen to about 40 per cent. of the maximum value.

This explanation fully accords with repeated curves in Fig. 4. From these it seems that the molecular change is reversed on cooling after a lapse of several hours, but that the deterioration is permanent. Consequently the second curve begins at a lower value, and lies altogether below the first one. Apparently the deterioration caused by the repeated heating diminishes the amount of molecular change, there being finally practically no improvement.

Commercial paraffin is not a simple body, but a mixture of several members of the paraffin series. It is, however, probable that both the molecular change and the decomposition occur in the same one of the series, and that finally the continued heating decomposes this member, and the molecular change disappears altogether.

Although *each* of the curves in Fig. 4 might be explained by the removal of a volatile substance, yet this explanation cannot be valid, for the drop of resistance due to standing for a day happened in each case, and the removal of an impurity would have effected a *permanent* improvement. Therefore a change of molecular state which cannot exist at lower temperatures, and is only slowly reversed on cooling, is the only apparent explanation. The slowness of all these changes is clearly indicated by the fact that a long-continued heating at 135°C produces a greater permanent deterioration than a short period of heating at 170°C., though, in the latter case, the deterioration per unit of time is much more rapid.

The practical result of these tests is to show that up to 100°C. no permanent injury to paraffin results, although its insulation resistance is enormously diminished and possesses only a very moderate value; but long-continued heating, up to temperatures of 130deg. or more, causes a very marked and permanent deterioration, such paraffin being rendered quite useless for resistanee coils and hardly satisfactory for condenser dielectrics, though the apparent resinisation as indicated by change of colour may be so slight as to be hardly perceptible except in a large mass.

Resin Oil.

Tests with the same apparatus were also taken on samples of resin oil supplied by Callender's Bitumen Company, being the

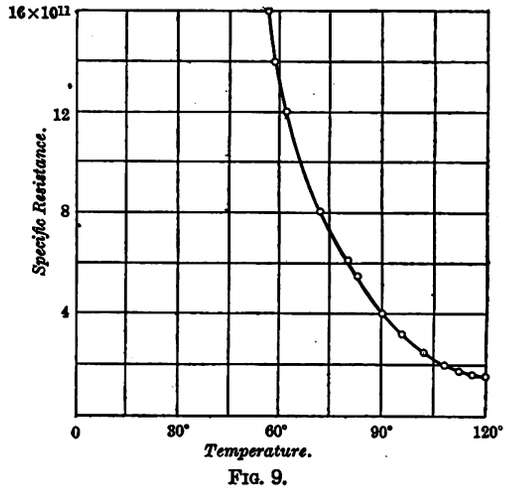

FIG. 9.

insulating oil used in the street junction boxes of the Liverpool Electric Supply Company's system. Tests were taken over the range of temperature likely to be attained in transformer coils or other oil-insulated apparatus.

The specific resistance at a temperature of 18°C. was found to be $3{\cdot}2 \times 10^{14}$ ohms.

From 18°C. the temperature was slowly raised, and a large fall of resistance was quickly apparent, as the oil became less viscid. At each temperature the resistance fell at first rapidly, then slowly, attaining a steady value after from 30 to 40 minutes. Fig. 8 shows the rate of deterioration at 45°C., this curve being typical of the variation at temperatures from about 20deg. to 50deg. As the temperature rose the resistance attained its constant value at each temperature more quickly, until at temperatures of about 80deg. and upwards the oil reached its minimum resistance almost simultaneously with the rise of temperature.

The fall of resistance was most rapid at quite moderate temperatures; at 25deg. the specific resistance had fallen to about one-fourth of its value at 18deg., and at 45deg. the value was about $\frac{1}{70}$th of the normal; at higher temperatures the deterioration was much less rapid, the resistance at

Digitized by Google

122deg. being only about $\frac{1}{40}$th of its value at 45deg. At from 110deg. to 120deg. the fall of resistance became very slow. Fig. 9 gives the curve of variation with temperature from 58deg. to 122deg., the latter being the final temperature attained.

The various values of the specific resistance at the different temperatures are given in the following table, the resistance difference between the limits of temperature being too great to plot a convenient curve :—

Temperature. Deg. Centigrade.	Specific resistance.	Temperature. Deg. Centigrade.	Specific resistance.
18	3275×10^{11}	62	12·0
23	2456·0	72	8·0
25	819·0	75	7·3
37	614·0	79	6·0
30	412·0	82	5·5
57	178·0	90	4·0
41	82·5	102	2·7
45	48·0	112	1·75
47	36·5	115	1·6
50	27·0	120	1·5
55	17·7	122	1·45
60	13·2		

The sample, on cooling to normal temperature, was found to be perfectly uninjured, and repeated heating within the range of temperature employed had no effect on the insulating properties of the oil at normal temperature, the resistance always returning to approximately the same value as that found for the first sample.

It is thus clearly shown that resin oil is quite free from permanent deterioration when exposed to high temperatures of the order ever likely to be met with in commercial apparatus. The reduction, however, in its insulating properties at not unusual temperatures, is sufficiently great to make it worthy of note in the use of resin oil as an insulating medium for high-tension transformer coils and other similar apparatus.

My thanks are due to Prof. Baily for his kind advice and assistance, and also to Mr. E. E. Johnston for help in carrying out the tests.

NON-INDUCTIVE RESISTANCES FOR TESTING PURPOSES.

In his last Cantor Lecture, Dr. J. A. Fleming described a form of inductionless resistance which he has devised and employed for a long time past in transformer testing and for other laboratory purposes. This form of resistance will probably be found to be very useful as soon as it is generally known. In every laboratory, testing room, or workshop where current is supplied at a constant pressure of 100 volts or so it becomes continually necessary to be able to take off small currents of various magnitudes for experimental purposes for working induction coils, motors, calibrating ammeters, and other numerous purposes for which the experimentalist requires current. Now that current is laid on to most private houses, and many experimentalists are engaged in private laboratories in work requiring induction coils, whether for the prosecution of the new photography or anything else, it becomes exceedingly useful to be able to tap off any required current taken from the 100-volt mains. Of course this can be done by incandescent lamps, but these have the great disadvantage that they give out a great deal of light, and therefore cannot be used where darkness is required.

Dr. Fleming's patent form of resistance consists essentially of two glass or porcelain head pieces having on them four or eight pins or studs. These head pieces are fixed on a brass rod, one of them being firmly attached to the rod, and the other loose. They are kept pressed apart by a strong spiral spring (see Fig. 1). Over these head pieces is wound longitudinally one or more bare fine wires, either of platinoid, manganese steel, nickel steel or any other suitable material. This wire is wound backwards and forwards longitudinally over these head pieces in such a way that the resistance has a small self-induction, and yet offers a very large surface for radiation and ventilation. The ends of the resistance wire are brought back to the fixed head piece, and there terminate in copper conducting wires. The spring forcing the loose head piece outwards always operates to keep the resistance wire tight, no matter how much it may have expanded by heating. This form of resistance coil, which Dr. Fleming calls a *cage*, constitutes the unit by which any required resistance is built up. Two such cages are generally fixed in a wooden frame

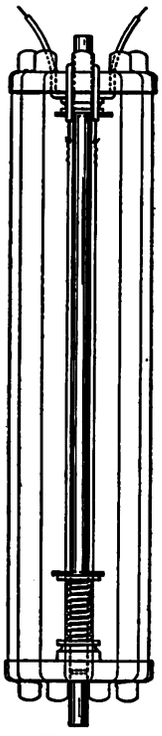

Fig. 1.

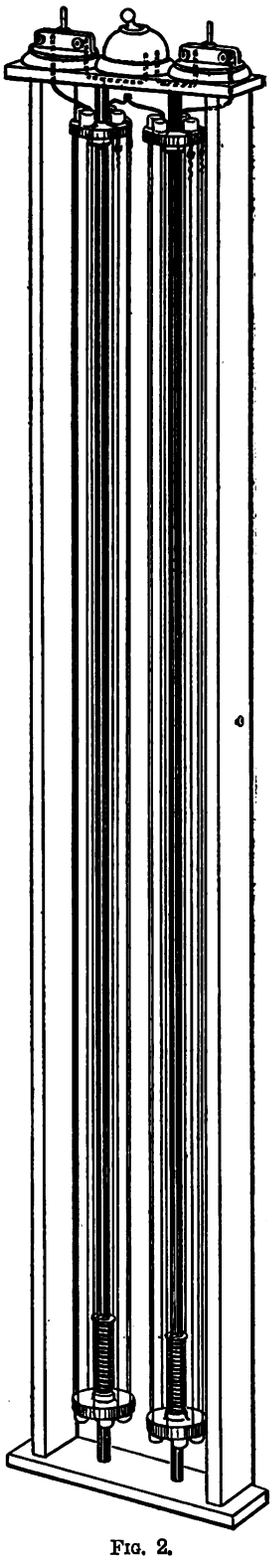

Fig. 2.

(see Fig. 2), the back of the frame being filled in with a sheet of perforated zinc. On the top of the frame is placed a switch and two porcelain cut-outs, the switch and cut-outs being in series with the resistances. These resistances can be made up to take any required current. A very useful size is a cage having a resistance of 100 ohms and capable of passing one ampere safely. Hence, when put across a 100-volt circuit, it can never

Digitized by Google

pass more than one ampere. A number of these frames carrying the cages can be fixed together by pins protruding from the wooden frame, and the resistances can be joined up so that the resistance wire with the switch in series is in parallel across a pair of main conductors, or they can so be joined up that the resistances are all in series, each resistance being capable of being short-circuited by the switch. Thus, for instance, 10 one-ampere cages can be joined up so as to give a united resistance of either 1,000 ohms capable of passing one ampere or 10 ohms capable of passing 10 amperes, the resistances being put in series or in parallel as required. It will thus be seen that a set of 10 such 1-ampere cages enables the experimentalist to draw off from the 100-volt circuit any required current from one-tenth ampere to 10 amperes. Twenty such 100-ohm cages can be joined in series to give a resistance of 2,000 ohms, or, if need be, can be formed to have a resistance of 4,000 or more ohms. Each cage is well insulated from its neighbour, and the whole resistance can be then placed across a 2,000-volt circuit taking up one-half or 1 ampere as required. In this way a safe resistance can be constructed, capable of being put across a high-pressure circuit and absorbing any required amount of power.

In a long investigation which Dr. Fleming made some time ago of the transformers of the City of London Electric Lighting Company, he employed such a series of cages placed across a high-pressure circuit, capable of carrying 3 amperes safely, and absorbing, therefore, at 2,000 volts, nearly 8 H.P. This resistance was employed for standardising the wattmeter used in testing large transformers of 50 and 30-kilowatt capacity. The remarkable thing about these resistances is that they radiate their heat at a low temperature and get rid of much of it by convection, so that when such an 8 H.P. resistance is placed across high-pressure circuit it is hardly possible to tell, when standing near it, whether the resistance is on or off; whereas, if 8 H.P. were being dissipated in incandescent lamps, it would be highly disagreeable to stand near them for any length of time, owing to the great radiation of light and heat.

These resistances are largely used in the Electrical Laboratory at University College for supplying currents for the experimental work, drawn off from the 100-volt mains fed by a secondary battery. One point in favour of this form of resistance is that it is very easily repaired. If a wire happens to become broken it is simply rewound again with a proper length of bare platinoid wire, and can be repaired at the expense of a few pence. Moreover, the insulation of this form of resistance is so high that the cages can with perfect safety be used across high-pressure circuits; resistances which take the shape of covered wire wound up in turns closely touching one another are not, on the other hand, over safe or satisfactory to use when dealing with very high pressures. Dr. Fleming's resistances can be obtained of most manufacturers of electrical apparatus.

MOTIVE POWER AND GEARING.*

BY E. TREMLETT CARTER.

(*Continued from page 308*).

Oil Engines.

Oil fuel is principally derived from petroleum. It is used (1) as a fuel for raising steam, (2) by explosion in an internal combustion engine, similar in action to a gas engine. It is with the latter use that we are here concerned. There are two distinct classes of internal combustion oil engines: (1) those consuming light and easily vaporised petroleum spirit; (2) those consuming heavy oils requiring the application of considerable heat to vaporise them.

Petroleum Spirit Engines.—Soon after the commercial use of the gas engine was commenced, engines working on a similar principle, but consuming benzoline and other light hydrocarbon liquids, were introduced, though with little success. The fuels requisite for these engines were of so volatile a nature that their flashing point was below ordinary temperatures; their vapours, when exposed to the air, were highly explosive, and therefore dangerous. It was this fact which impeded the introduction of these engines and enormously restricted their application. The explosive charge was generally obtained by passing air through some porous fabric soaked in the liquid fuel, when the air became heavily charged with the vapour of the spirit. Drawn thus into the cylinder, the air became converted into an explosive charge, which was fired by means of an electric spark or by a flame in the rear of the cylinder. Recently there has been a revival of this class of motor, for use in mechanically-propelled road carriages; and it would seem that the revival promises considerable extension in the near future. In the modern types the Otto cycle is adhered to, and generally the electric spark or hot tube ignition; and special precautions are taken to ensure against the accidental ignition or explosion of the oil.

Petroleum Oil Engines.—The earlier petroleum engines were incapable of using ordinary burning oils, owing to the difficulty which was experienced in properly vaporising these heavier distillates of petroleum. Yet, the safety of the oil engine depended upon the invention of a successful method of using these heavy oils. Brayton, in 1872, was the first to attempt the use of burning oils in an internal combustion engine; and he succeeded in running an engine with petroleum of 0·850 specific gravity. An inefficient cycle, together with faulty mechanical construction, combined to make the Brayton engine somewhat uneconomical. The consumption of oil was about 2·16lb. per I.H.P. per hour. The thermodynamic efficiency was only 6 per cent. The engine was constructed to give an impulse every outward stroke, during which stroke the compressed air and petroleum vapour were drawn into the cylinder, and gradual combustion ensued, the pressure of the combustion being sufficient to propel the piston. Ignition took place within a small recess in the back of the cylinder, this recess being partitioned off from the vaporiser by means of several grids of perforated metal. Flame continually burned within this small recess.

To Messrs. Priestman Bros., however, must the credit be given for having first succeeded in constructing an engine to work on the Otto cycle with ordinary burning oils. Thus they have the honour of being the pioneers of the modern oil engine. The essential feature in their invention is the preparation of the oil in a vaporiser, placed externally to the engine, in such a manner that it might be drawn with air into the engine cylinder and treated like the explosive charge of an ordinary gas engine. The object to be attained was to convert the liquid oil into a state so nearly resembling gas that it would neither condense within the cylinder nor deposit tarry residues either in the vaporiser or in the engine. Though differing in the manner in which this is attained, all modern oil engines depend for their action upon this principle.

Priestman Oil Engine.—In the Priestman oil engine the liquid fuel is prepared for combustion by being sprayed into a heated chamber adjoining the cylinder. This chamber is called the vaporiser; and, though heated by a small lamp when the engine is about to be started, it is normally kept hot by the circulation of the exhaust gases around it. A longitudinal section (Fig. 82) shows the details of the vaporiser and spray maker, a separate section of the latter being shown in Fig. 83. Referring first of all to the latter diagram, it will be seen that the nozzle consists of two passages, both opening into a conical discharge passage. The innermost passage is for the oil, while the annular passage surrounding it conducts a blast of air towards the oil jet, and thereby causes the oil to be broken into spray. The position of this nozzle is indicated at E, in Fig. 82, and it will be seen that it is situated at the entrance to the vaporising chamber. Surrounding the nozzle are a number of air passages, D, through which air passes from the chamber B, in the end cover of the vaporiser. The direction of the jets of air issuing from these orifices D is such as further to spray the oil before it passes into the heated chamber, as well as to admix the spray with a plentiful supply of air. The air, entering by the passages D, is drawn in by the valve L through the passage F; but the air which passes through the annular orifice in the nozzle E, by the passage J, is

Digitized by Google

forced by a special pump in the frame of the engine. The oil is forced from the oil tank under the same pressure, through the passage K. It will be seen that the oil passes through a hole in the governor spindle H, at M. The governor, actuating the lever I, regulates the amount of throttling of the oil at this point, and thus adjusts to the load the amount of oil supplied for each explosive charge. The engine is not permitted to miss explosions, but regulation is entirely obtained by variation of the richness of each charge. The indicator diagrams taken from one of these engines, and referred to more particularly later, show how the variation of the composition of the charge affects the indicated

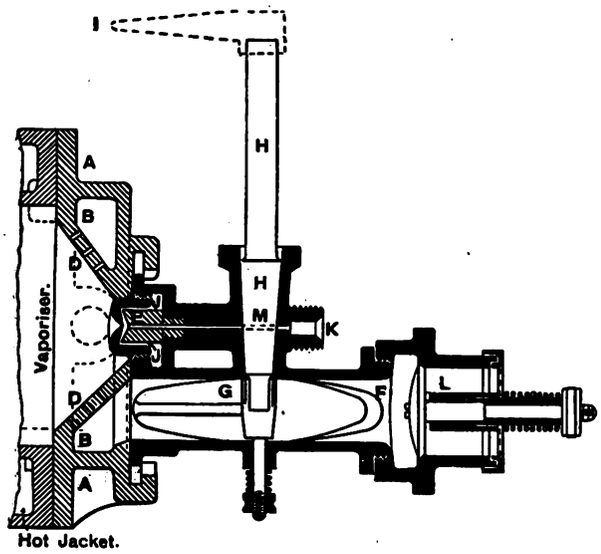

FIG. 82.—Priestman Oil Engine. Longitudinal Section of Vaporiser and Spraying Apparatus.

work done per cycle. It should be mentioned, in regard to the vaporiser, that one of the chief merits in preparing the oil fuel in this way is that the oil is only gently heated and is not altered in chemical composition by its passage through the vaporiser. It is sufficient to raise the temperature of the oil spray enough to ensure that it will be held in suspension in the air until ignition; a higher temperature might, and if it were much higher certainly would, decompose the oil, giving rise to tarry matter which would choke the passages and injure the cylinder liner.

Having been drawn through the vaporiser, by the indraught of the forward "charging" stroke of the piston, the oil and air enter the cylinder through one of two mushroom valves in

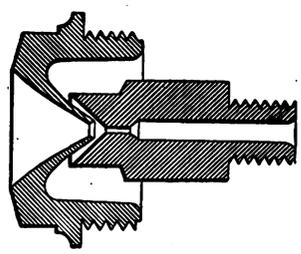

FIG. 83.—Priestman Oil Engine. Section of Spray-making Nozzle.

the cylinder end, as shown in Figs. 84 and 85. During the next stroke of the piston this charge is compressed into a large clearance space in the rear of the cylinder, the extent of this space being indicated in Fig. 85, the piston in this figure being on the inner centre. Immediately this inner centre is passed an electric spark is caused to pass between two electrodes, I, on the insulated igniter K (Fig. 84). A working stroke ensues, followed by the exhaust of the greater part of the gases shrough the other mushroom valve in the cylinder end.

The type of Priestman engine most commonly used for driving a dynamo is the horizontal type, the latest form of which is shown in longitudinal section in Fig. 85. The footnote to this illustration will make the position and action of the principal parts clear; but reference may be made to one or two of the details of the engine which are not shown. Upon one end of the crank shaft there is a single reduction spur gear, which turns a short eccentric shaft at half the speed of the crank shaft. The eccentric upon this has three actions: (1) It propels the pumps which supply the enclosed chamber C with oil and compressed air; (2) it actuates the exhaust valve at the cylinder end; and (3) it closes at the proper moment the circuit of the current which generates the igniting spark. The closing of this circuit is effected by means of a metal knob on the eccentric rod at about the middle of its length. This rod, as it oscillates, carries the knob between two insulated metal springs, which are included in the circuit of the spark-generating apparatus. When the knob passes between these two springs it metallically connects them, and allows of the development of a spark between the electrodes within the cylinder of the engine.

An automatic starting apparatus is usually used on engines of more than 4 H.P. to 6 H.P. This is a simple and effective apparatus, and consists of a hand pump, H, together with a number of special hand valves, for supplying the passages for the explosive gases before the engine gets into regular action. To begin with, the vaporiser is warmed by means of the

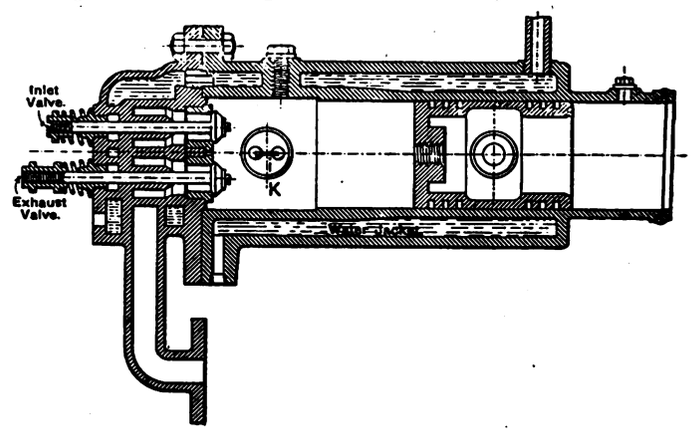

FIG. 84.—Priestman Oil Engine. Longitudinal Section of Cylinder, Valves and Piston.

lamp L. While this is going on, the hand pump will be used to force air at about 25lb. pressure (the pressure being indicated on a small gauge) into the chamber C. The flywheel will now be turned round so as to bring the igniting knob into contact with the two springs, the piston being ready to make a forward stroke. With the electric battery temporarily disconnected, the compressed air from the enclosed chamber, C, is permitted to pass through the vaporiser into the cylinder, filling the clearance space with an explosive charge. The closing of the battery circuit will now cause a spark to pass, which will fire the charge and start the engine.

Performance of the Priestman Engine.—Notwithstanding the extra duty of pumping oil and air for its own consumption, the Priestman oil engine appears to give very excellent results in regard to its mechanical efficiency. Prof. Unwin found that an engine running at 207 revolutions per minute, and developing 7·40 I.H.P., absorbed 0·64 H.P. in engine friction, developing 6·76 B.H.P. This represented the extraordinarily high mechanical efficiency of 91 per cent. The same engine, running at 204 revolutions per minute, and developing 9·86 I.H.P., was found to have a mechanical efficiency of 82 per cent. The former results were obtained with "Russoline," and the latter with American oil. About 16·12 per cent. of the total heat was utilised as *indicated* work, leaving 47·54 per cent. to be carried off by the jacket water, 26·72 per cent. by the exhaust gases, and 9·61 per cent. by other losses. The consumption of oil per brake horse-power per hour was 0·941b. of "Russoline," in the first-named test, and 0·841b. of American oil in the second-named test. In general practice the author has found that this type of engine consumes approximately one pint of petroleum per brake horse-power per hour; and in setting off the cost of this against that of steam or of gas, it must be

Digitized by Google

remembered that this supplies not only fuel for one horse-power hour, but cylinder lubrication as well. The excellence of the graded charge system of governing in the Priestman engine is illustrated by the accompanying set of indicator diagrams (Fig. 86), which were taken from an oil engine used for electric lighting at Alnwick Castle.

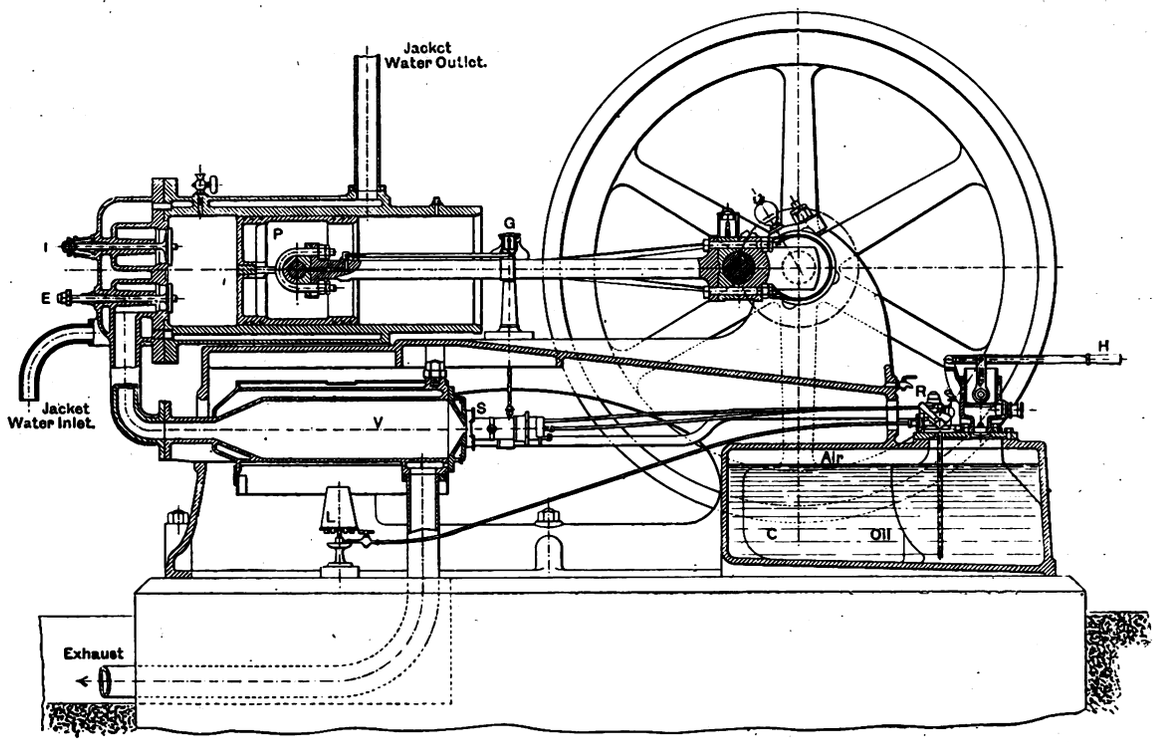

FIG. 85.—Priestman Oil Engine. Longitudinal Section.

S = Spray Producer. L = Lamp for Heating Vaporiser at Starting. P = Piston. E = Exhaust Valve. I = Admission Valve.

Hornsby-Akroyd Oil Engine.—The Hornsby-Akroyd oil engine represents an attempt to simplify and reduce the number of the working parts of an engine designed to work with the heaviest and cheapest mineral oils in the market. The most noticeable feature is the absence of a separate

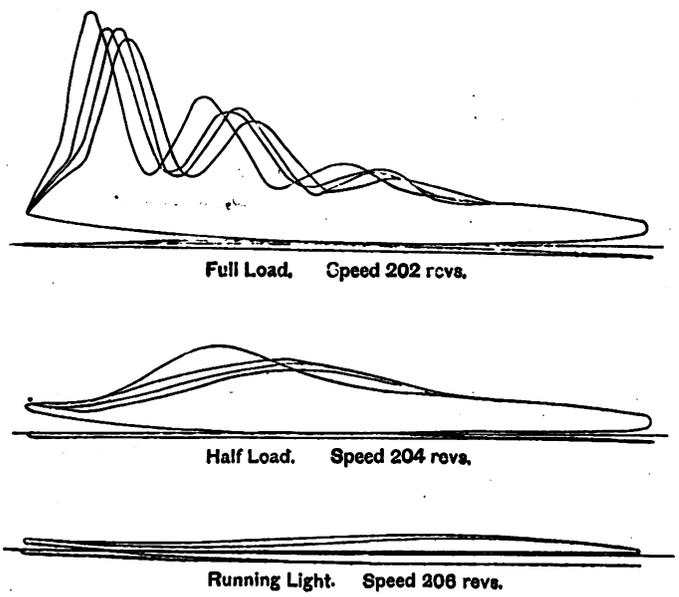

FIG. 86.—Indicator Diagrams of Priestman Oil Engine, showing Action of Graded Charge System of Governing.

chamber for vaporising the fuel, the oil being pumped directly, drop by drop, into a gasefying combustion chamber immediately behind the cylinder and forming an extension of the cylinder space. This chamber is normally at a low red heat, its heat initially being obtained from a lamp temporarily used, and being afterwards maintained by the ignition of the oil within this chamber. There is no water jacket around this combustion chamber, but air is permitted to circulate around it, to keep the temperature even. A water jacket surrounds that part of the cylinder which is immediately outside the path traversed by the piston. The heat of the exhaust gases is partially recovered, by being imparted to the air as it is drawn into the combustion chamber previously to compression. No external means of ignition is found necessary, the compression of the heated air into the space containing the gasefied oil being enough to set up an explosion, and certain enough in its action to render premature firing unlikely to happen. Messrs. Hornsby and Sons, of Grantham, are the makers of this engine; and it is claimed by them that oils of so great a density as 0·854 (flashing point, 220°F.) may be consumed in it, in continuous work. The consumption of petroleum oils of the density used for lighting purposes—0·800 to 0·850—is about one pint per brake horse-power per hour. The reduction of the fuel to a gaseous state, instead of a state of vapour, results in the charge being very much drier than in the Priestman type of engine, and necessitates the use of cylinder lubrication.

"Trusty" Oil Engine.—The ingenious idea to place the oil vaporiser around the hottest end of the cylinder, in the form of a jacket, occurred to Mr. Knight, of Farnham, whose name has been prominent in connection with the use of oil engines for road carriages. The patent in connection with this invention was acquired by Messrs. Weyman and Hitchcock, of Guildford; and their engine embodying it is called the "Trusty" oil engine. The "Otto" cycle is followed; and ignition is now by means of a heated tube. The vaporisation in this engine takes place at a sufficiently high temperature to gasefy the oil; but as a rule only slight residue, or none at all, will occur in the vaporising jacket. The engine has been exhaustively tested by Mr. W. Worby Beaumont, who has kindly favoured the author with a copy of his Report on the trials. This Report states that the "Trusty" oil engine will work with heavy oils, including the Broxbourne (paraffin) and lighthouse oils, having a flashing point as high as 240°F. No trouble was found to arise from deposits; and perfect combustion of the oil gas took place in the cylinder.

During the trials, the particulars of which are tabulated below, an American petroleum known as "Royal Daylight" was

Digitized by Google

used, having a specific gravity of 0·802 (one pint = 1·0025lb.). The calorific value was assumed to be 19,500 B.T.U. per pound. The engine was rated at 6 B.H.P., and was tested at full, half and no load. Separate measurement was made of the amount of oil required to heat the ignition tube. This item was found to vary from 6oz. to 7oz. per hour, and was practically independent of the load on the engine. The following particulars give the exact results of the trials :—

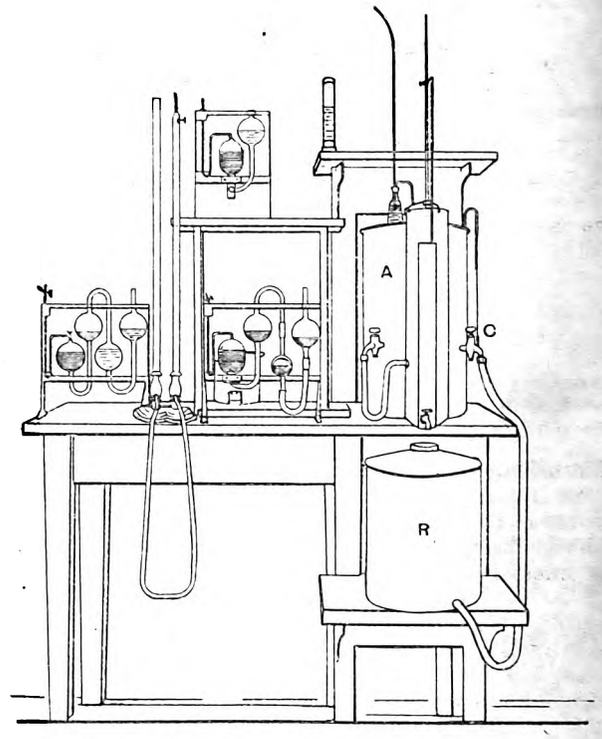
(To be concluded).

FURNACE GAS ANALYSING APPARATUS.

The best authorities on boiler practice are agreed that it is most important to make regular and frequent analyses of the furnace gases, in order to find out whether, and to what extent, the combustion is economical. The chief points to be determined are the percentages of CO and CO_2, as well as that of the free oxygen. Engineers have been hindered from systematically adopting this practice, partly from ignorance of its importance, but more particularly from lack of reliable apparatus, which would enable a representative analysis to be made with expedition and without great technical skill. At Messrs. Bryan Donkin and Co.'s engineering works in Bermondsey, we have recently seen in operation a set of apparatus, which, we judge, will meet the requirements of the case very thoroughly. This firm is not only adopting it for its own boiler furnaces, but is also, we believe, making and supplying the complete equipment. The apparatus is constructed for use on the "Waller" system, a method of gas analysis which was first introduced into Messrs. Waller's works in Belgium. In the accompanying illustration the chief details of the apparatus are shown, just as they would be arranged for regular work, the illustration having been prepared from a photograph of the Bermondsey plant.

To sample the gases the brass vessel or aspirator A is first completely filled with water. The upper part of this vessel is in communication, through a small metal tube, with the part of the furnace whence the sample is to be drawn. The lower part is connected to a drip cock, from which the water trickles into a receiving vessel R, thereby gradually drawing a sample of furnace gas into the aspirator A. By adjusting the drip cock the period over which the sampling is done can be regulated; and this period may conveniently extend from 8 or 10 hours up to 24 hours. When the complete sample has been collected it will be analysed for CO_2, CO, and oxygen. To refill the aspirator with water it suffices to open the cock C, communicating with the bottom of the receiving vessel R, and to lift this latter vessel above the level of the aspirator for a few moments.

Having collected the sample, to commence an analysis a measured volume (usually 100cc.) will be transferred from the aspirator to a burette; and this known volume will then be subjected to volumetric analysis by passing it through a succession of U-tubes and bulbs containing the various reagents. Into the details of the process it is not necessary to enter, but it may be stated that in a very short space of time the percentages of the chief ingredients, previously named, may be estimated to a degree sufficiently close for practical purposes. The percentage of CO_2 which will indicate good practice will vary with the class of coal burned, and may lie between 11 per cent. for bituminous coals and 15 per cent. for anthracite coals. The percentage of CO should, of course, be as near to zero as possible. There will always be a certain necessary percentage of free oxygen, and the amount of this will depend not only on the class of coal, but also on the type and construction of the furnace, and on the draught, &c. If there is not sufficient free oxygen there will certainly be some CO, and there may also be smoke. The right percentage of free oxygen will therefore be readily determined after a little experience. A comparison between the best percentages and those actually found by analysis, will often reveal defects in the boiler plant or in the stoking. For example, it may show that air is leaking into the flues through cracks in the brickwork, or that the stoker is not handling his fire properly. A firm of engineers which uses this analysing apparatus has devised a system of bonuses for the



stokers, the amount of the bonus rising with the percentage of CO_2 obtained. There was one stoker who, whatever boiler he was put in charge of, always managed to head the list, a fact which shows two things—firstly, that gas analysis will reveal what the stokers are doing; and secondly, that the duty of any given boiler largely depends on the stoker.

RECENT DEVELOPMENTS IN GAS ENGINES.

At a meeting of the Institution of Civil Engineers on January 28th a Paper was read on "Recent Developments in Gas Engines," by Mr. Dugald Clerk, Assoc.M.Inst.C.E. The author stated that the theory of the gas engine outlined in a Paper read by him before the Institution in 1882 was now generally accepted, while the stratification theory had vanished. Great advances had since been made in gas engine construction, and the heat efficiency of such engines had been much improved, while their dimensions and power had increased. Engines working on the Otto cycle had been proved to be the best adapted of all yet invented for present needs, and their popularity had gradually led to the extinction of other types. The mechanical development of the Otto type was illustrated by the comparison of drawings of an engine built thirteen years ago with those of one recently constructed. The advance in heat efficiency was almost, if not completely, due to increase in the pressure of compression before explosion. It was shown that each

Digitized by Google

step of diminished gas consumption of the Crossley Otto engine was attended by an increase in compression. The results were summarised in the following table, showing the absolute indicated efficiency of Crossley Otto engines of similar size since 1882 :—

—	Efficiency.	Pressure of compression above atmosphere.
		Lb. per sq. in.
1882-88	0 16	33·0
1888-94	0·19	66·6
1894.....	0·25	87·5

These results showed that economy increased with the compression, but it was open to question whether the increased compression completely accounted for the improved performance. Theoretical efficiencies, as well as the actual efficiencies obtained in the gas engine, were shown in a table, from which it appeared that the economy had improved, chiefly on account of the increased compression. It was noted that in every case the actual indicated efficiency obtained from the various gas engines was about one-half that which would have been given by an ideal air engine following the same cycle in a perfect manner without loss to the sides of the cylinder. Also, that the actual efficiency improved more rapidly with the increase of compression than did the thermodynamic advantage due to the compression. Thus, when the theoretical efficiency was 0·33, the actual experimental efficiency was $0·33 \times 0·45 = 0·15$; and with the theoretical efficiency 0·39, the actual efficiency was $0·39 \times 0·48 = 0·19$; while with 0·428 theoretical efficiency, the actual efficiency was $0·428 \times 0·58 = 0·25$. The ratio of actual to ideal efficiency thus rose with increase of compression from 0·45 to 0 58, and this, it was stated, meant that with higher compressions, two advantages were obtained, the thermodynamic advantage, due to improvement in cycle, and a further advantage due to diminution of the proportional loss of heat to the cylinder walls.

In comparing the earlier with the recent Crossley Otto gas engine, it was pointed out that the great differences between the two engines which resulted in the superior economy of the later, were found in (*a*) the abandonment of the flame slide-valve ignition, and the substitution for it of ignition by an incandescent tube of metal or other material ; (*b*) the diminution in the relative volume of the compression space ; (*c*) the improved proportioning of the values and ports in order to minimise the throttling of the charges during the inlet period and the back pressure of the exhaust gases during discharge. This statement was illustrated by reference to numerous indicator diagrams. The author described his tests of the new Crossley Otto scavenging engine, stating that although it was highly desirable to discharge all the exhaust gases and replace them by pure air, as so long contended by him, yet that such displacement was not accountable for more than 5 per cent. of the improvement produced in the Otto scavenging engine. It was stated that scavenging possessed practical advantages quite apart from improvement in gas consumption. Otto gas engines, constructed by Messrs. Andrew and Co., of Reddish, and by Messrs. T. B. Barker and Co., of Birmingham, were also described and illustrated, and the various peculiarities of the different Otto-cycle engines were pointed out. It was stated in discussing these engines that engineers had not sufficiently recognised the importance of limiting the port surface to the utmost, in order to minimise the cooling surface in contact with the intensely hot gases. The Barker engine was referred to as one in which this point had been well kept in mind by the designer.

From a mechanical point of view the Otto cycle was a very imperfect one, allowing at most an impulse for every two revolutions of the crankshaft for each single-acting power cylinder ; but the mechanical imperfections of the engine had until now been more than compensated by the simplicity of the single cylinder and piston, and the readiness with which the practical conditions of charging, exploding, expanding and exhausting could be made to comply with the requirements of economical working. The great difficulty of the problems involved in impulse-every-revolution gas engines was then referred to, and the author described several engines which had been designed with a view to overcome those difficulties. In the first engine built by the author, early in 1878, there were two cylinders, each having a diameter of 6in , with a length of stroke of 8in., one a pump cylinder, and the other a motor cylinder. The pump crank followed the motor crank at right angles, and it pumped the mixture of gas and air into an intermediate reservoir through a check valve. From this reservoir the explosive mixture was supplied to the motor cylinder by means of a slide valve, and was compressed in the reservoir to a pressure of 70lb. per square inch above the atmosphere. The motor piston moved back to the end of the cylinder, leaving only a mechanical clearance, and the exhaust valve was shut a little early in order to cushion the piston, as was done with steam engines. The motor piston moved forward from the end of its stroke about 2in., taking in the compressed mixture from the reservoir ; the slide valve then cut off the supply, and ignition was effected by an incandescent platinum cage carried in the slide. The engine was, the author believed, the first compression gas engine working by explosion ever built which gave an impulse for each revolution of the crankshaft. The difficulties which prevented the success of this type of engine were described.

The author then considered the modifications still to be made in the indicator diagram of a gas engine to further increase its heat efficiency, and in this he particularly referred to the Otto cycle, although he stated that it was to be remembered that impulse-every-revolution engines could now be arranged to produce any of the results brought about by the Otto engine. It was pointed out that the actual indicated efficiency of a gas engine increased with the theoretical efficiency, and that the actual efficiency varied between 0·45 and 0·58 of the theoretical efficiency. It was also stated that the indicated efficiency increased with the dimensions of the engine, other things being similar, when the ratio of compression space—and therefore the theoretical efficiency—remained constant. Thus an engine having a cylinder 9½in. in diameter with a length of stroke of 18in. had a theoretical efficiency of 0·40, and gave an indicated efficiency of 0·19, or 0·47 of that theoretically attainable. An engine having a cylinder 14in. in diameter, with a length of stroke of 25in., of which the theoretical efficiency was 0·41, gave an actual efficiency of 0·277, that was 0·675 of the theoretical efficiency. The actual efficiency, instead of being only 0·47 of the theoretical, increased to 0·675 without practical change in the compression. This comparison proved that efficiency increased with the dimensions. It was pointed out that a limit was reached to the increase of efficiency due to increase of dimensions, and the conditions were calculated. It was shown that further economy might be obtained by increasing the compression and expansion, but it was considered that for high compressions and large gas engines it would be advisable to adopt the compound principle, although the conditions of success, for compound gas engines, were not yet fully understood.

In conclusion, the author considered that the gas engine would yet assuredly be applied upon railways and to ships, just as it was now used in factories ; its principles were better understood, and engineers were daily improving their knowledge of the properties of flame, and the means of utilising flame in place of steam.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-Day) FRIDAY, February 7th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Students' Meeting. Paper to be read: "On the Construction of a Form of Wheatstone's Bridge Box," by Gustave J. Lemmens.

MONDAY, February 10th.

NOW READY.—Vol. XXXV. of "THE ELECTRICIAN," bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

The published price of Volumes previous to Vol. XXXV. is 12s. 6d. post free 13s. 6d. Many of these Volumes are very scarce.

CHEMICAL FACT AND THEORY.

It is noteworthy that, while the interpretation of electromagnetic and electrostatic phenomena has progressed from a purely electrical standpoint to one which is becoming increasingly mechanical or dynamic, the interpretation of chemical phenomena has taken a converse development, and is gradually progressing from a dynamical character to one which is becoming more and more completely electrical. In the early days of "current electricity" electrical phenomena were expressed in terms of two quantities—electricity and magnetism—each of which was non-dynamical and *sui generis* as regards the conception scientists held of it; and it has been from this crude and incoördinated stage that electrical science has developed into its modern expression in terms of mechanical quantities. Indeed, the avowed purpose of the pioneers of electrical theory is its ultimate expression rationally in terms of the three fundamental quantities—of length, mass and time. On the other hand, chemistry has but recently emerged from an era in which chemical phenomena were vaguely and somewhat inconclusively expressed in terms of "chemical affinities," forces between the atoms of a dynamical or statical nature, and "bonds," by which the molecules were held intact, and the "affinities" of the component atoms "satisfied." Such phraseology savoured more of the language of the alchemists than that of rational science; yet, in its underlying conception, it was mechanical in its nature, and it had as its main basis the conception of attractions between the atoms of chemically-reacting bodies. There was a half-truth in all this complication of bonds and affinities; and when the light of electrical science was shed upon chemical phenomena it began to be seen how closely allied these phenomena were to those of the electric charge and the electric circuit. First, it dawned upon scientific thinkers that the chemical forces between atoms were due to electrical charges upon those same atoms; and later, it has come to be seen that many, and probably all, chemical reactions between atoms are of a nature which has its simplest expression in a voltaic element circuited through a conductor.

The reprint which we recently made of a Paper by Prof. J. J. THOMSON, on "The Relation between the Atom and the Charge of Electricity Carried by It," has already been commented upon. It is not too much to say that the researches which formed the basis of that Paper, and the deductions which Prof. THOMSON has drawn therefrom, mark one of the most important stages in the history of chemical theory. A careful perusal of that Paper can hardly fail to carry conviction in regard to the main propositions, as to the dependence of chemical reaction upon the actual electrification and the normal electro-chemical properties of the atoms concerned. Closely associated with this subject is another reprint, which we commence this week—namely, the Address delivered by Prof. H. E. ARMSTRONG before the Chemical Society, on "The Nature of Chemical Change and the Conditions which Determine It." While, in these two articles, there is a great diversity of scope, that by Prof. ARMSTRONG covering, by way of illustration, a much wider range of actual chemical phenomena, it will be seen that in their inferences and conclusions they are practically identical. "Chemical action," writes Prof. THOMSON, "does not, in general, take place between a single pair of molecules alone in the field, but requires the formation of aggregates either of the inter-acting molecules or of some third substance which is either a conductor of electricity or has a large specific inductive capacity." On this head, Prof. ARMSTRONG, who has aptly described chemical action as "reversed electrolysis," states that "in any case in which chemical action is to take place it is essential that the system operated on shall contain a material of the nature of an electrolyte," a statement which becomes unified with that quoted from Prof. THOMSON'S article by the following further quotation from Prof. ARMSTRONG'S address: "The essential moment conditioning the occurrence of chemical change, according to the view of which I am an advocate, is the formation of a conducting system in which electrolysis can occur, and within which, as already said, change will necessarily take place so soon as the system is established, if exothermic change be possible under the conditions—as in any voltaic cell."

Quite startling support of this theory is given by the behaviour, when in the pure state, of certain pairs of substances which, when mixed in a state of slight impurity—as when slightly moistened—are violently active. Reference need only be made to one instance, but several others, equally convincing, might be cited. At the Oxford meeting of the British Association, Mr. H. B. BAKER showed that perfectly dry and pure ammonia could be admixed with hydrochloric acid in a similar condition, without chemical change; whereas, almost every schoolboy knows that admixture of the ordinary gases is accompanied by energetic combination.

Prof. ARMSTRONG expresses the hope that the behaviour of the non-metallic elements will eventually justify a classification of the elements according to whether they electrically conduct or insulate, defining "a metal as an element which conducts, and a non-metal as an element which insulates." The first difficulty, that non-metals do not perfectly insulate, may possibly be disposed of in the majority of cases by assuming that the imperfection arises from impurity, the impure components setting up electrolytic conduction. A great deal of importance has been attached to the influence of impurities; and throughout his address Prof. ARMSTRONG insists upon "the great importance of the part played by 'impurity' in Nature in conditioning chemical change." The next difficulty is met with when we attempt to classify the metalloids: arsenic, tellurium, &c. These cannot be regarded as being conductors purely by virtue of their impurities; and the only apparent way to get them into line with the definition of a metal is to transfer them to the class of metals, which step many chemists would resist. But the most insuperable obstacle, to our mind, is the element carbon. To regard this as a metal would stretch the imagination to the breaking point; while to be told that it is not a conductor is just as liable to stagger the practical electrician. Yet Prof. ARMSTRONG does not hesitates to tell us that it is not. "The conductivity of what is so wrongly called carbon," he tells us, "in the form used for electric light purposes, is well known to be electrolytic in character, and is, therefore, most probably conditioned by the presence of salts, and not a specific property of the modification of the element present is such materials." Now, what is so wrongly called carbon is used by electrical engineers in two forms, in the incandescence lamp filament and in the arc-lamp "carbon" rod. The process of making each of these, but more especially the latter, is conducive to the existence of salts in the finished article. Yet in neither case can the percentage of these salts be much in excess of a mere trace; and in the glow-lamp filament, with careful manufacture, the trace might easily be made untraceable. Are we, then, to credit that the conductivity of these articles of carbon, falsely so-called, is entirely due to the electrolytic influence of their impurities? A comparison between the conductivity of salts and that of the maligned but useful articles, shows that the conductivity of the "carbon" is very considerably the greater and makes it difficult to accept this explanation. We are, therefore, still face to face with the question as to the class into which elementary carbon should be placed. Carbon is, in many of its chemical relationships, somewhat an anomaly. It would be better to assume that in this particular respect its behaviour is anomalous, rather than on the one hand to force it into a class to which it does not apparently belong, or, on the other hand, to deny it properties which it gives such striking evidence of possessing.

In regarding the theory propounded in his address as a "theory of *association*," as opposed to the older theory of *dissociation*, we think Prof. ARMSTRONG may have assumed an antagonism which does not really exist. We are at one with him in thinking that "the main article of faith in the dissociationist's creed, that a certain very limited class of compounds —electrolytes—fall to pieces, as it were, more or less completely on entering into solution," necessitates "a profound distinction being made between electrolytes and other compound molecules generally." Profound indeed, but not necessarily a radical distinction, for it seems to us that the dissociation theory, in support of a limited application of which there is so much direct evidence, may be but a restricted portion of a more widely-extending theory—an all-embracing theory such as that of *association*. It is conceivable that in certain cases a preliminary process of dissociation may precede the chemical or electro-chemical processes of association, which are represented by the obvious and ultimate reaction between the bodies concerned. This as we understand it is the point of Prof. J. J. THOMSON'S illustration of the combination between hydrogen and chlorine, in the Paper to which we have already referred (*The Electrician*, January 3rd, pp. 324 and 344). He first assumes the existence of an external dissociating agency, and proceeds to show that half of the H or Cl atoms would be positively and half negatively electrified. Unless conducting circuits can be formed between the dissociated atoms, as by the presence of a third substance, this state of affairs will not alter. If, however, such circuits can be formed, a re-adjustment of the atomic charges will take place, all the H becoming positive and all the Cl negative,

Digitized by Google

with the result that chemical combination might ensue. Taken conjointly, it seems to us that the two articles by Profs. ARMSTRONG and THOMSON not only emphasise the importance of viewing all chemical phenomena from the electrical standpoint, but they give good ground for hope that the details of the true theory will be found to reconcile the "association" with the "dissociation" hypotheses.

THE NATURE OF CHEMICAL CHANGE AND THE CONDITIONS WHICH DETERMINE IT.*

"All the facts show us that that power commonly called chemical affinity can be communicated to a distance through the metals and certain forms of carbon; that the electric current is only another form of the forces of chemical affinity; that its power is in proportion to the chemical affinities producing it; that when it is deficient in force it may be helped by calling in chemical aid, the want in the former being made up by an equivalent of the latter; that, in other words, *the forces termed chemical affinity and electricity are one and the same.*" †—Faraday's "Experimental Researches in Electricity," 1834, Series VIII., § 918.

Foremost among the problems to which during recent years attention has been devoted is that of the nature of chemical change. Whilst English workers especially have made most important contributions to our knowledge of the conditions under which change will occur, foreign workers have been most active and successful in developing mathematical methods of treating the subject. Indeed, the statement recently made in a prominent chemical journal that "it has certainly become impossible to read chemical theory without a working knowledge of the calculus" is a striking comment on the alterations in the conditions under which the chemist will work in the future, which must serve to remind us how very different a preparation students must now undergo if they desire to thoroughly master the theories of our science.

The subject first came under consideration in this Society just 10 years ago. In the discussion on Mr. Brereton Baker's Paper on combustion in dried gases I ventured to insist that the evidence that action did not take place between two substances was so strong that chemists would ere long be forced to form a definite conception of the nature of chemical action and of the conditions under which chemical action could take place; and I then pointed out that physicists were in advance of chemists, drawing attention to Ayrton and Perry's Paper on the contact theory of voltaic action, in which it is directly stated that Ohm's well-known law is equally applicable to electrical and chemical changes.‡

On the occasion in question I defined chemical action as *reversed electrolysis*, and explicity stated that in any case in which chemical action is to take place it is essential that the system operated on shall contain a material of the nature of an electrolyte. The expression "chemical action" was used as including all cases of exothermic change, cases of endothermic change being obviously comparable with direct electrolyses, as in all such cases energy from without must be impressed on the system.

Later in the year, at the British Association meeting at Aberdeen, in my address to the Chemical Section, I discussed the matter more fully, and then stated in so many words that the conditions which obtain in any voltaic element are those which must be fulfilled in every case of chemical action. I carefully pointed out, however, that there was nothing new in this, and to justify my assertion drew attention to various passages in Faraday's "Experimental Researches in Electricity," in which such a doctrine is laid down in the clearest possible terms.§ Let me here again say that nothing is to me more surprising than the continued disregard of Faraday's teaching on this subject. We know that in regard to purely electrical questions, even in this country, it was not until Clerk Maxwell came forward as his interpreter that attention became riveted upon his conceptions; and abroad, even, Clerk Maxwell was disregarded until Hertz's experimental demonstration ensured that respect being paid to his pleadings which they were so long denied. Faraday's views regarding chemical action have never yet received proper notice, although the language in which they are expressed is so simple and direct that they cannot be misunderstood, and their completeness is surprising.

But one conception has been added to Faraday's teaching—that of "electrolytic or ionic dissociation or ionisation." Although introduced by Clausius in 1857, it lay dormant until it was reintroduced and applied by Arrhenius in 1884, who gave to the hypothesis a quantitative form; but it did not become popular until 1887, when Van't Hoff introduced the conception of osmotic pressure. The successful application of the hypothesis in explanation of the abnormally high results obtained in the case of conducting solutions at once secured for it a very large measure of support. Whatever view may ultimately be taken of the hypothesis—whether it be retained as a permanent addition to our theories or not—its introduction has been eminently fruitful of results, and an already too voluminous literature of the subject has grown up with surprising rapidity. Yet it appears to me that it has been accepted by a particular school—at the head of which stands Ostwald, and who regard and treat all unbelievers as heretics worthy of the stake—not as a mere working hypothesis, but as an absolute creed, without any sufficient attempt having been made to discuss its *general* probability. And the application of Avogadro's axiom to solutions, however successful as affording a mathematical method of discussing results, in principle involves the complete disregard of the essential difference between the liquid and gaseous states, and of the fact that in liquids the molecules are subject to a control which they mutually exercise and which distinguishes the liquid from the gaseous state. Also it must not be forgotten that the arguments made use of apply almost entirely only to weak solutions—to solutions to which a law of simple proportionality may be expected to apply; that, in fact, the region explored is one in which the rate of change is represented practically by a straight line. Lastly, it is applicable only to electrolytes. Personally, I am still entirely unconvinced of the validity of the hypothesis, although no one can be more willing to admit that, in so far as *weak* solutions are concerned, a "law" has been discovered which is broadly true *in mathematical form*, however open to question the fundamental premises may be on which it is based. I am satisfied also that the phenomena of chemical change are, as a rule, far more complex in character than is assumed by the advocates of the hypothesis.

If electrolysis, and therefore electrolytic conduction, be—as I contend and have long contended—conditioned *by a conjoint influence* exercised by the solvent A and the dissolved substance B; there is, I imagine, no reason why other phenomena in which the conjoint influence of A and B comes into account should not be expressible in mathematically similar ways. In extenuation of such heresy, I can only quote Clerk Maxwell's argument that if in a battery a septum be used which diminishes the diffusion, it is probable it will increase in exactly the same ratio the resistance of the element, because electrolytic conduction is a process the mathematical laws of which have the same form as those of diffusion, and whatever interferes with one must interfere equally with the other, the only difference being that diffusion is always going on whilst the current flows only when the battery is in action.

It has always appeared to me that the chief objection to be urged against the ionic dissociation hypothesis is the fact that, of the very large number of compounds known to us, extraordinarily few are electrolytes—not even metallic chlorides generally are conductors, but only a very limited number; and it is particularly remarkable that whilst such inactive substances as lead and silver chlorides, when fused, are among the best conductors known, aluminium chloride—one of the most active compounds with which we are acquainted—is apparently not an electrolyte. Electrolytes are clearly a very limited class, and if we consider the general properties of compounds which conduct more or less readily, whether alone or in solution, and contrast them with compounds which are practically dielectrics, it is impossible to discover any good reason why "ionic disruption" should take place in the case of the one set and not in that of the other. And if, confining our attention to acids, we contrast those which in solution are apparently good conductors with those that are bad conductors, there is again no satisfactory "motive" for so considerable a difference discoverable; for example, taking sulphuric and acetic acids, why should the former suffer ionic dissociation so readily and to so considerable an extent, and the latter to so slight an extent? I imagine that it is fair, for this purpose, to regard the acids as modified water, and to assume that the slight tendency of water to undergo ionic dissociation—of which more later on—is enhanced by the association of the water with the oxygenated group, and that whereas sulphuric anhydride has a marked effect, acetic anhydride has a very slight one. Yet this is hardly satisfactory, and would probably involve the conclusion that sulphuric acid should diminish in conductivity as the temperature is raised, as it then dissociates into anhydride and water; the very different behaviour of sulphuric and acetic acids when vaporised, the former but not the latter undergoing dissociation, may be regarded as an indication that a similar change does not take place in the case of

* Abstract of an address delivered by Dr. H. E. Armstrong before the Chemical Society.

† The italics are Faraday's own.

‡ "Hitherto chemists have only employed the two ideas of chemical affinity and the amount of chemical action, but we have shown that these ideas are simplified when regarded as electromotive force of contact and currents of electricity. To connect the two ideas we have a third—viz., *resistance*, and the electrical law of Ohm becomes the chemical law—*the quantity of chemical action in unit time equals the sum of a great number of terms, each of which is an electromotive force divided by a resistance.*" (Ayrton and Perry, *Proc.* Roy. Soc., 1867, 27, 227.)

§ Series VII., §§ 850, 858, 859; VIII., §§ 869, 918.

Digitized by Google

acetic acid, and, therefore, it might be supposed that acetic acid would undergo ionic dissociation to a far greater extent than is assumed to be the case as a consequence of the anhydride retaining its influence.

It may possibly be contended, as it has been in the case of water, that compounds generally are conductors to a very slight extent; but as all bad conductors seem to become worse conductors as they are more carefully purified, the burden of proof rests upon those who make such an assertion; and it is not in accord with the fact that very many such compounds are as active as compounds which conduct well, and which are therefore, by hypothesis, more or less fully dissociated. For example, acid chlorides generally act on alcohols generally with very considerable readiness under conditions under which the halhydrides produce but a slight effect.

With regard to water itself, to argue, as Arrhenius, Ostwald and others have done, from the hydrolytic action of water on the salts of weak acids and bases, that water to a certain but very small extent contains ions—that is, H and OH, is but to beg the question entirely, and a clear case of reasoning in a circle.

The recent redetermination of the electrical conductivity of water by F. Kohlrausch and Heidweiller gives the value $0{\cdot}04 \cdot 10^{-10}$ at 18deg., instead of $0{\cdot}25 \cdot 10^{-10}$ previously arrived at by F. Kohlrausch. These authors have deduced from their results a value for the conductivity of *pure* water—viz., $10^{10} \cdot \kappa = -0{\cdot}0361$. They calculate that if this conductivity be due to the presence of water ions a cubic metre of water at 18deg. would contain 0·08 milligram of dissociated hydrogen ions, and point out that if present only in this excessively minute proportion there would still be milliards of atoms of hydrogen per cubic millimetre, and neighbouring atoms would be separated by distances of the order of light waves in dimension. These conclusions, however, are based on the acceptance of the view put forward by Arrhenius, that the dissociated ions alone conduct the current—from my point of view, therefore, it is a case of deducing one unknown with the aid of another unknown—of proving one assumption by another assumption, which is admittedly an unsatisfactory proceeding. I venture to think that it is still open to question whether pure water, indeed whether any *pure* substance outside a very limited number perhaps, such as the silver haloïds, &c., be an electrolyte. Minute in the highest degree as the amount of impurity in the water examined by Kohlrausch and Heidweiller must have been, yet even this may have exercised a very considerable effect, and in fact there is clear evidence in the Paper that an extremely minute amount of impurity does so act. Moreover, the difference between the lowest observed value and the corrected value appears disproportionately small when the reduction of the value previously obtained by Kohlrausch, effected by the removal of what after all must have been a very minute amount of impurity, is considered. The point is one of the utmost importance, and cannot be lightly brushed aside.

The methods made use of in calculating the amount of ionic dissociation of water are apparently all open to the criticism that they are based on eminently hypothetical premises, and it is particularly open to question whether the phenomena from which fundamental values have been deduced have received the proper interpretation. For example, the origin of the E.M.F. developed in liquid couples such as have been studied by Worm Müller, and much later by Nernst, and of the concentration currents of von Helmholtz, is by no means clear. Nernst assumes that in such cases forces acting at the electrode surfaces are entirely eliminated, but, if so, it is not clear why any more than when an acid neutralises an alkali an E.M.F. should be developed, for I imagine that in all such cases the changes take place within closed circuits. In fine, I am inclined to doubt whether polarisation effects can be regarded as eliminated; the inquiry must be included with that into the existence of a true contact difference of potential independent of chemical change. The values deduced by Ostwald are based on the study of couples of the form :—platinum-hydrogen | acid | alkali | hydrogen-platinum, and it is assumed that the E.M.F. developed is due to the formation at the one electrode of water from the hydrogen and the OH ions in the liquid, and at the other of hydrogen from hydrogen ions in the liquid and the hydrogen of the electrode. Unfortunately the description promised of the experiments has not yet been given, and it is therefore difficult to criticise them; it is not impossible, however, that the real cause of the E.M.F. was dissolved oxygen.

Pure liquids do not conduct, according to Kohlrausch, because (as Ostwald has put it, *Brit. Assoc. Report*, 1890, 335) their molecules have no space within which to resolve themselves into ions, and it is therefore not improbable that water would conduct electrolytically—and I presume that Ostwald meant even to imply that it would be a good conductor, as he immediately afterwards spoke of water too containing ions to a certain but very small extent—if we could find a suitable solvent for it. But we never have found a suitable solvent—unless it be hydrogen chloride. The fact that single substances such as the silver haloïds, when liquefied, readily conduct, would appear in itself to be a sufficient argument in controversion of Kohlrausch's explanation of the influence of the solvent. Moreover, it is to be supposed that any liquid capable of acting as a solvent should condition electrolysis if the function of the solvent be but to act as a screen.

As a matter of fact, there is good reason to think that among liquids, *water is the only effective solvent that we can use!*

Alcoholic and some other solutions, it is true, conduct more or less well, but it is by no means improbable that when every precaution is taken to deal with highly purified materials, and especially to dehydrate the alcohol as fully as possible, such solutions will be found to be practically destitute of conducting power. This is the more likely now that Perkin has established the incorrectness of the supposition that until recently has always been made that hydrogen chloride, when dissolved in alcohol, acts fairly readily on it (*Trans.*, 1894, 23). The observations made by Coldridge showing that solutions of hydrogen chloride in stannic chloride are but slightly conductive are also significant (*Phil. Mag.*, 1890, 29, 383).*

If it be assumed that even pure water is to some slight extent dissociated, it is, at least, probable that liquid hydrogen chloride would contain some small proportion of ions prior to admixture with water; and, in point of fact, it is impossible to urge any reason why the one compound should be regarded as more dissociated than the other in the pure state. Yet the "ionists" not only assert that when hydrogen chloride dissolves in water it becomes almost completely separated into its ions, but make the arbitrary assumption that practically it alone is dissociated, the extent to which the water is dissociated being, indeed, diminished by its admixture with hydrogen chloride, according to their view. This question is of fundamental importance as bearing on the validity of the argument on which Ostwald and others have sought to base a method of determining the heat of formation of water from its ions and on the interpretation they have given of the changes attending the neutralisation of acids by alkalis.

I long ago insisted that we have no right to draw any marked distinction between hydrogen chloride on the one hand and water on the other, inasmuch as, in so far as the chemist can test them, they do not differ markedly in stability. I venture to think that no sufficient answer has been made to my objection. To say that analogous compounds such as NCl_3 and PCl_3, or N_2O_5, and P_2O_5, exhibit differences equal to those manifested between HCl and H_2O is incorrect and beside the point—they are vastly different in stability; water and hydrogen chloride are not (compare Ostwald *Zeit. Physikal. Chem.*, 7, 418). So long as it was asserted that water, *per se*, underwent no change, the position was, perhaps, in a measure defensible; but when it is argued that pure water does dissociate into its ions, this advantage is sacrificed; the possibility of a change taking place in pure water being granted, it is no longer justifiable to draw a hard and fast distinction between water and hydrogen chloride. This argument is most materially strengthened by the fact that the majority of compounds are not electrolytes.

Although those who uphold the ionic hypothesis regard the solvent as mainly inactive, yet they do not deny that it may exert some influence comparable with that exercised by raising the temperature (compare Ostwald, *Zeit. Physikal. Chem.*, 1891, 7, 421; *Lehrbuch*, 2nd Ed, 1, 776). But it is impossible to gainsay that it has an altogether extraordinary effect in many cases. For example, in the case of hydrogen chloride, it is only necessary to mix this with nine molecular proportions of water to obtain a solution of maximum conductivity, in which, if we are to believe the ionists, nearly the whole of the dissolved hydrogen chloride is resolved into its ions. It is scarcely conceivable, however, that so small a proportion of water molecules should suffice to practically entirely prevent the reunion of ions which cannot by hypothesis be kept apart in the absence of the solvent; and the conclusion is the more striking if it be remembered that, according to Ostwald, hydrogen silicon fluoride only begins to undergo hydrolysis when present in a solution to the extent of 1 per cent., a very large proportion of water being required to prevent the reversal of the interchange $H_2SiF_6 + 2H_2O = SiO_2 + 6HF$—in other words, a compound which is almost generally regarded as a molecular compound is far less readily broken up† than one of the most stable of "atomic compounds!"

Or, taking the case of sulphuric acid, how are we to satisfactorily explain by the ionic dissociation hypothesis the fact established by F. Kohlrausch that the amount of acid required to form a solution of maximum conductivity increases as the temperature rises, from 30·2 at 0deg. to 35·4 per cent. at 70deg? If, however, electrolysis occur within a system of acid and water molecules, as a rise of temperature would promote the occurrence of dissociation in such a system, a larger proportion of acid would be required at higher temperatures to maintain the system of the same average composition.

In fact I believe it is impossible to deny that the solvent is intensely active, and that it is no mere screen preventing re-com-

* These observations require to be repeated, taking every possible precaution to exclude moisture.

† Incidentally it may be asked, how is the formation of hydrogen silicon fluoride from solid silica and hydrogen fluoride to be explained; and how are we to reconcile the fact that action takes place with such extreme readiness when hydrogen fluoride is by hypothesis so slightly dissociated?

Digitized by Google

bination of the ions—it is rather to be supposed that the occurrence of electrolysis in a solution of hydrogen chloride, for example, is in some way directly conditioned by the conjoint influence of the solvent and the dissolved substance; that electrolysis is not merely an affair of atoms of ions, but of complex molecular systems; and most important of all—*that water, perhaps, is altogether peculiar among solvents as furnishing solutions which can be electrolysed.*

Having thus considered some of the apparent anomalies of the ionic dissociation hypothesis, I may now briefly refer to evidence of its insufficiency in the case of interactions, in which substances are concerned which are not electrolytes—a condition which is not fulfilled in the case of a very large number, indeed an overwhelming majority of carbon compounds. No doubt it may be asserted that, at all events, the agent used is dissociated, and that consequently the compound which is attacked is subject to the action of ions just as the zinc is in a voltaic cell. But is this a sufficient explanation? Consider the case of the hydrolysis of sugar—admitting, for the sake of argument, that when this is effected by dilute acid, the ions of the acid and of water either simultaneously or successively attack the sugar molecule; how are we to explain the action of the enzyme invertase? This cannot well be regarded as an electrolyte; and it is not sufficient even to assert that it does, to some slight extent, undergo dissociation into ions—it acts so readily, more readily even than an acid which, by hypothesis, is to a very great extent dissociated, that if at all dissociated it is presumably highly dissociated. The selective action of enzymes on glucosides, &c., is also very remarkable, as acids do not act selectively.

Difficulties such as appear to beset the ionic dissociation hypothesis are not met with in considering the alternative *association* hypothesis, and if this can be shown to be compatible with electrical requirements, it should command more general consideration—in fact, there have been many indications of late that this view is once more coming into prominence. Briefly stated, the hypothesis involves the assumption that complication, not simplification, precedes most, if not all, chemical changes; that complex molecular systems are first formed from the interacting substances, and that these, on breaking down, suffer rearrangement of the parts—such rearrangement taking place in consequence of elements which were previously separate being brought into one common "sphere of activity" within which it is possible for them to interact. The function of condensing and other agents—of catalysts generally—on this hypothesis is that of collecting into one system the various elements necessary for the occurrence of a particular change. Such systems may be regarded as, and, in fact, would be, closed voltaic circuits or potential circuits requiring only the removal of a resistance to convert them into closed circuits. The action of aluminium chloride, for example, in conditioning the formation of homologues of benzene from the two substances benzene and methyl chloride—both undoubtedly dielectrics, I imagine, which when together alone are entirely without action on each other, may be ascribed to the formation of an unstable compound of both with the metallic chloride. In like manner it may be supposed that ferric chloride conditions the interaction of bromine and benzene by combining with both, and so bringing them both within each other's range in an unstable system. The function of enzymes in promoting hydrolysis, referred to above, on this hypothesis, consists in bringing water into conjunction with the carbohydrate by combining with both. Lastly, if it be assumed that a solution consists of dissociable molecular compounds of solvent and dissolved substance, the occurrence of change on dissolving two substances in a common solvent, as in the case of methyl iodide and silver nitrate in alcohol, may often be conditioned by the solvent acting as "condensing agent" or catalyst.

Prof. Fitzgerald, who has carefully considered this hypothesis, if I rightly understand his argument, seems to see no difficulty in applying it to the explanation of electrical phenomena. The modification of Grotthus's hypothesis, which he has suggested, is certainly one which appears to be in entire harmony with chemical experience, and it is so important that the question should be fully discussed, that I will venture to quote his statements almost in their entirety from the *Brit. Assoc. Report*, 1890, 142, where they are too likely to escape general attention:—

"Electrolysis has been explained on two different theories by Grotthus and Clausius. As generally received they differ. Grotthus's theory, as generally given, assumes that the molecules in an electrolyte are both polarised and moved by the electric forces within the liquid. This seems so far untenable that it would appear that double the electric force would double both the polarisation and the motion of the molecules, and so should produce four times the electrolysis. The objection, however, assumes that we know the causes resisting the motion, and with proper and not very improbable assumptions as to the resistance to motion depending on it and on the polarisation, a linear relation between current and electromotive force, *i.e.*, obedience to Ohm's law seems possible. A modification of Grotthus's hypothesis in the direction of Clausius's is, however, possible. Suppose that when polarised, the molecules *drew one another apart* at a rate proportional to the polarisation. This at once makes the relation between electric force and the decomposition a linear one, and so satisfies Ohm's law in the case of small currents It also so far agrees with Clausius's hypothesis that it explains electrolysis and double decomposition as properties of the same kind. The molecules in a liquid will occasionally be arranged by accident in a proper polarised condition in a closed circuit for drawing one another apart, and if the circuit includes molecules of different kinds there will result double decomposition. There seem to be very serious difficulties in supposing that uncombined atoms are for any finite time free in the liquid; and the supposition that it is a particular arrangement that is required before exchanges take place, and that with this arrangement exchanges take place of their own accord, seems to explain electrolysis and double decomposition without supposing free atoms to exist within the liquid. . . .

"There are some other phenomena that have been explained upon the supposition that free atoms are gadding about in a liquid. Such are the lowering of the boiling and freezing points by solutions of salts and their effect on osmotic pressure. If dissociated atoms are going about in a liquid as in a gas, it seems impossible but that they must diffuse at different rates; and that this is not observed seems conclusive against the hypothesis, no matter what else the hypothesis may explain. Consider solution simply. Why does chloride of sodium dissolve in water? There must be some strong affinity between the two of a chemical or semi-chemical nature to break up the cohesion of the crystal; and it seems reasonable to assume that this same affinity keeps the molecules of NaCl moving about among the water molecules so that they diffuse about. Now if the forces drawing them about be independent of the nature of the molecule, most of the phenomena explained by gaseous laws are explained. Pressure of a gas depends, at any temperature, on the number of molecules and not on their kind. This is Avogadro's law, by which molecular weights are calculated; and if the forces drawing a molecule about in a liquid are independent of the kind of molecule, the very same law of pressure would hold, the pressure forwards of molecules of different kinds would depend on their number only, and in the same way as Avogadro's law would enable molecular weights to be calculated. In this connection it is well to state that some bodies may be much better able to produce pressure than others, because of their being more easily polarised, *i.e.*, turned into an effective direction. A molecule which could be easily turned into an effective direction would be about twice as effective as a molecule which went about in a higgledy-piggledy way; and one would consequently expect electrolytes to produce more, nearly double, the osmotic pressure that others did. As to the changes of boiling and freezing points, they seem explicable by exactly the same hypothesis. The reduction of vapour pressure by molecular affinity of dissolved salt would depend only on the number of molecules of salt if all salts have the same molecular affinity for water; and the same would apply to the change in freezing point. Hence all these phenomena are explained without assuming free atoms, and they are all explained by what can hardly avoid being a *vera causa*, namely, whatever affinities they are that cause solution, which latter is an unexplained phenomenon on the dissociation hypothesis. That it is reasonable to think that the forces keeping the molecules of salt moving about in the water are independent of the nature of the salt, appears from various considerations. In the first place these forces are in all probability due to the residual affinities of the non-metallic elements. These same forces are probably the cause of crystallisation. These are old suggestions. That these residual affinities should be nearly the same for different combinations does not seem at all unlikely. . . ."

I have said above that the complex systems within which chemical change is assumed to take place would be closed voltaic circuits. It is to be expected that evidence of the occurrence of electrolysis and chemical change as interdependent phenomena within such ssytems will frequently evade detection, as more often than not we have to do with circuits which cannot be explored; and on this account also our power of availing ourselves of the energy of chemical change is strictly limited. Probably no discovery could be made which would be of greater technical importance than the discovery of a method of burning fuel electrically, *i.e.*, so as to produce electricity instead of heat. Hydrogen may be burnt electrically in the manner discovered by Grove, apparently because it is possible by means of platinum to connect both hydrogen and oxygen in circuit with an electrolyte such as diluted sulphuric acid; but we have not yet succeeded in discovering a method of "plating" a conductor with carbonic oxide which would enable us to arrange it in a circuit with oxygen. If this could be done, probably the problem would be soon solved. In the case of solid fuel the problem presents other difficulties, especially that arising from the want of suitable electrolytes; thus, although heated lead oxide is readily reduced by carbon, it does not behave as an electrolyte when the attempt is made to burn carbon electrically by means of it, the action being purely local. In like manner we have to discover a means of converting nitrogen into either ammonia or a nitrate comparable with that which apparently enables the papilionaceous plant or associated bacteroid to assimilate nitrogen from the atmosphere.

Having broadly laid down the principle that chemical changes consist in the exchange of ions, and therefore take place exclusively between ions, the "ionists" may be presumed to accept the view that chemical and electrolytic changes generally are synonymous operations. This being the case, it is remarkable how little has been done by way of applying the hypothesis except as a means of correcting values obtained in working with solutions which behave as electrolytes. The expansion and application of Faraday's conceptions to the explanation of chemical change generally appears, indeed, to have been retarded rather than advanced by the

Digitized by Google

assertions formulated by the advocates of ionisation as a precedent cause of chemical change; indeed, Faraday's writings appear to have received no notice from the school. No attempt has been made to differentiate electrolytes from dielectrics by explaining either the essential peculiarities of either class or the co-ordination of composition, *i.e.*, structure and function; or to explain the extreme readiness with which dielectrics are in many cases acted on; or to define the conditions under which chemical change will occur; or to explain the readiness with which a minute amount of "impurity" will often condition change.

(To be continued.)

CATHODE RAYS.*

BY G. JAUMANN.

M. H. Poincaré gave in the *Comptes Rendus* of December 3, 1895, an equation showing that cathode rays follow a general law which I only found separately for all the special cases. But he assumes that his equation gives the direction of propagation of cathode rays, which I cannot agree to. This equation gives the speed of propagation of the wave front, which has no general relation to the speed or direction of the ray.

For rarefied homogeneous gases in the static state M. Poincaré's equation takes the form of

$$k\frac{d\theta}{dt}+X_0\frac{d\theta}{dx}+Y_0\frac{d\theta}{dy}+Z_0\frac{d\theta}{dz}=0.$$

It is an equation of the first order which not only the variable θ but all the variables of the ray will satisfy. Let n be the direction of the normal to the wave front; we get for c the speed of the wave front

$$c=\frac{1}{k}\left[X_0\cos(n,x)+Y_0\cos(n,y)+Z_0\cos(n,z)\right].$$

It is impossible to make any deduction as to the direction of the rays. Perhaps the rays coincide with the normals to the wave front, as I think they do, then the speed of the rays is equal to c. Perhaps the rays follow the lines of force (X_0 Y_0 Z_0), as M. Poincaré thinks; then the speed of the rays would be independent of the inclination of the plane of the wave to the direction of the ray.

M. Poincaré concedes that wave fronts are deflected by the magnet. That being so, I find it difficult to understand how the direction and speed of the rays can be independent of the magnetic force. I only know three ways of finding the direction of the rays.

1. Huygens' method, which, as I have shown in my Paper, is only true for rays following a differential equation of the second order (light rays, acoustic rays, &c.), and not for the rays of the first order of my theory. This method would give the result that M. Poincaré has enunciated, but it gives results that are demonstrably wrong as to the propagation of the wave surface and as to reflection. Moreover, the elementary surface of Huygens degenerates in this case into a single point, which means that the undulation is propagated from the centre of disturbance in a single line, and not in all directions, which no one can believe.

2. Kirchoff's method, which is based on the ill-defined direction of the flux of energy.

3. The method employed by me in one case, and which is based on the distribution of intensity. If in the integral we can find lines where the intensity of the oscillations is constant, these are the directions of the rays. This method told me that the direction of the rays is everywhere normal to the wave fronts deflected by a magnetic force. In the same way, I do not think cathode rays follow the lines of electric force if the rays have magnetic components.

Hence I need not as yet modify my hypotheses. But it would not be difficult to do so in order to get over M. Poincaré's objection, which is very interesting, since it opens a discussion on the direction of the rays of the first order, a question which presented so many difficulties in the case of luminous rays of the second order.

Institution of Mechanical Engineers.—At the annual general meeting of the members of this Institution, held last week in the theatre of the Institution of Civil Engineers, it was stated that at the end of last year the number of names in all classes on the roll of the Institution was 2,270, as compared with 2,222 at the end of the previous year. The Council have bought a site at Storey's-gate, with the view of providing a permanent home for the Institution. Contracts are being prepared for a building, and it was hoped that next year the house would be completed.

* *Comptes Rendus*, Vol. CXXII, No. 2. Reply to a Note by M. H. Poincaré, for which see *The Electrician*, January 31st, p. 453.

BOARD OF TRADE REVISED ELECTRIC LIGHTING RULES.

In our issue of May 31, 1895, we published the draft revised electric lighting rules proposed by the Board of Trade for securing the safety of the public. In our issue of November 22, 1895, we published a full report of the Conference held at the Westminster Town Hall on the previous Tuesday and Wednesday. In our issue of December 13, 1895, we published the Report of the Special Committee appointed by the Board of Trade to consider the definition of "low pressure." To-day the cycle of events is completed by the publication of the new Rules in their final form.

DEFINITIONS.

In the following regulations—

The expression "the Order" means the ——— Order.

The expression "the Undertakers" means the Undertakers for the purposes of the Order,

The expression "consumer's wires" means any electric lines on a consumer's premises which are connected with the service lines of the Undertakers at the consumer's terminals.

The expression "aerial line" means any electric line which is placed above ground and in the open air.

The expression "pressure" means the difference of electrical potential between any two conductors through which a supply of energy is given, or between any part of either conductor and the earth; and—

(*a*) Where the conditions of the supply are such that the pressure may at any time exceed 500 volts if continuous, or 250 volts if alternating, but cannot exceed 3,000 volts, whether continuous or alternating, the supply shall be deemed a high-pressure supply;

(*b*) Where the conditions of the supply are such that the pressure may on either system exceed 3,000 volts, the supply shall be deemed an extra high-pressure supply.

The expressions "high pressure" and "extra high pressure" [respectively are used in relation to electric lines, conductors, circuits, and apparatus] according to the conditions of the supply delivered through the same or particular portions thereof.

Where these regulations require any metallic body to be "efficiently connected with earth," it shall be connected with the general mass of earth in such manner as will ensure at all times an immediate and safe discharge of electrical energy.

Other expressions to which meanings are assigned in the Order or in the above-mentioned Acts have the same respective meanings in these Regulations.

A.—REGULATIONS FOR SECURING THE SAFETY OF THE PUBLIC.

GENERAL.

Pressure of supply to consumers. 1. The pressure of a supply delivered to any consumer shall not exceed 250 volts at any pair of terminals, except with the express approval of the Board of Trade. Such approval will only be given for special purposes and on the joint application of the consumer and the Undertakers, and the supply will be subject to such further regulations as the Board of Trade may from time to time prescribe.

Pressure of supply to transforming apparatus. 2. The pressure of a supply delivered to a transforming station or to transforming apparatus on a consumer's premises may exceed 250 volts, but shall not exceed the limits of high pressure.

Limitations of extra high-pressure supply. 3. An extra high-pressure supply shall not be given except to distributing stations or other premises in the sole occupation of the Undertakers, and with the written consent of the Board of Trade, and subject to such regulations and conditions as the Board may prescribe.

Maximum current in conductors. 4. The maximum working current in any conductor shall not be sufficient to raise the temperature of the conductor or any part thereof to such an extent as to materially alter the physical condition or specific resistance of the insulating covering, if any, or in any case to raise such temperature to a greater extent than 30°F.; the cross-sectional area and conductivity at joints must be sufficient to avoid local heating, and the joints must be protected against corrosion.

Minimum size of conductors. 5. The sectional area of the conductor in any electric line laid or erected in any street after the date of these regulations shall not be less than the area of a circle of one-tenth of an inch diameter, and where the conductor is formed of a strand of wires, each separate wire shall be at least as large as No. 20 standard wire gauge.

Specification of insulating material. 6. All material used for insulating electric lines or apparatus shall be of the best quality, and thoroughly durable and efficient, having regard to the conditions of its use. Suitable provision shall be made for the protection of the insulating material against injury or removal.

If the protection so provided be wholly or partly metallic it shall be efficiently connected with earth.

Insulation test of electric lines. 7. Every main shall be tested for insulation after having been placed in position and before it is used for the purposes of supply, the testing pressure being at least 200 volts, and the Undertakers shall duly record the results of the tests of each main, or section of a main.

Digitized by Google

Maintenance of insulation. 8. The insulation of every complete circuit used for the supply of energy, including all machinery, apparatus, and devices forming part of, or in connection with, such circuit, shall be so maintained that the leakage current shall not under any conditions exceed one-thousandth part of the maximum supply current; and suitable means shall be provided for the immediate indication and localisation of leakage. Every leakage shall be remedied without delay.

Every such circuit shall be tested for insulation at least once in every week, and the Undertakers shall duly record the results of the testings.

Provided that where the Board of Trade have approved of any part of any electric circuit being connected with earth, the provisions of this regulation shall not apply to that circuit so long as the connection with earth exists.

High-pressure conductors to be covered. 9. Every high-pressure conductor laid after the date of these regulations shall be continuously covered with insulating material to a thickness of not less than one-tenth part of an inch, and in cases where the extreme difference of potential in the circuit exceeds 2,000 volts, the thickness of insulating material shall not be less in inches or parts of an inch than the number obtained by dividing the number expressing the volts by 20,000.

Testing of insulation of all parts of any high-pressure circuit. 10. A high-pressure circuit shall not be brought into use unless the insulation of every part thereof has withstood the continuous application, during one hour, of pressure exceeding the maximum pressure to which it is intended to be subjected in use—that is to say, in the case of every electric line a pressure twice the said maximum pressure, and in the case of every machine, device, or apparatus, a pressure 50 per cent. greater than the said maximum pressure.

The Undertakers shall duly record the results of each test.

Quick-acting cut-off for high-pressure lines, &c. 11. Every high-pressure electric line, conductor, or other apparatus shall be protected by a suitable automatic quick-acting cut-off.

Provided that it shall not be incumbent upon the Undertakers to provide such a cut-off for the outer conductor of a concentric main which is, with the approval of the Board of Trade, efficiently connected with earth.

Transformers. 12. In every case where a high-pressure supply is transformed for the purpose of supply to one or more consumers, some suitable automatic and quick-acting means shall be provided to protect the consumer's wires from any accidental contact with or leakage from the high-pressure system, either within or without the transforming apparatus.

Limit of power in high-pressure electric line. 13. A high-pressure electric line shall not be used for the transmission of more than 300,000 watts, or in the case of an aerial line 50,000 watts, except with the consent in writing of the Board of Trade, and efficient means shall be provided to prevent this limit being at any time exceeded.

Protection from lightning. 14. Where any portion of any electric line or any support for an electric line is exposed in such a position as to be liable to injury from lightning, it shall be efficiently protected against such injury.

Accidents to be reported. 15. Where any accident by explosion or fire, or any other accident of such kind as to have caused or to be likely to have caused loss of life or personal injury has occurred at any part of any electric line or work, the Undertakers shall give immediate notice thereof to the Board of Trade.

Aerial Lines where Erected with the Necessary Consents.

Maximum intervals between supports. 16. Every aerial line shall be attached to supports at intervals not exceeding 200ft. where the direction of the line is straight, or 150ft. where the direction is curved, or where the line makes a horizontal angle at the point of support.

Supports, construction and erection of. 17. Every support of an aerial line shall be of a durable material, and properly stayed against forces due to wind pressure, change of direction of the line, or unequal lengths of span. The factor of safety shall be for aerial lines and suspending wires at least six, and for all other parts of the structure at least 12, taking the maximum possible wind pressure at 50lbs. per square foot. No addition need be made for a possible accumulation of snow.

Attachment of aerial lines. 18. Aerial lines shall be attached to insulators, and shall be so guarded that they cannot fall away from the support. Conductors covered with insulating material shall not be attached to the insulators by un-insulated metal binders.

Height from ground and distance from buildings, &c. 19. An aerial line shall not in any part thereof be at a less height from the ground than 18ft.,* or where it crosses a street, 30ft.,* or within 5ft. measured horizontally or 7ft. measured vertically from any building or erection other than a support for the line, except where brought into a building for the purpose of supply.

Service lines from aerial lines. 20. Service lines from aerial lines shall be led as directly as possible to insulators firmly attached to some portion of the consumer's premises which is not accessible to any person without the use of a ladder or other special appliance, and from this point of attachment they shall be enclosed and protected in accordance with the subsequent regulations as to electric lines on the consumer's premises. Every portion of any service line which is outside a building but is within 7ft. from the building shall be completely enclosed in stout india-rubber tubing.

Angle of crossing thoroughfares. 21. Where an aerial line crosses a street, the angle between the line and the direction of the street at the place of crossing shall not be less than 60deg., and the spans shall be as short as possible.

* Note.—In the County of London 20ft. and 35ft.

Crossing wires, &c. 22. Where an aerial line crosses, or is in proximity to, any metallic substance, precautions shall be taken by the Undertakers against the possibility of the line coming into contact with the metallic substance or of the metallic substance coming into contact with the line by breakage or otherwise.

Suspending wires. 23. Every high-pressure aerial line shall be efficiently suspended by means of insulating ligaments to suspending wires, so that the weight of the line does not produce any sensible stress in the direction of its length. All suspending wires, if of iron or steel, shall be galvanised.

Discharge of pressure in case of fire. 24. In the case of any high-pressure aerial line exceeding one half mile in total length, means shall be provided whereby the pressure may be discharged from any portion of the line erected over or alongside of any building or buildings without loss of time in case of fire or other emergency.

Maintenance. 25. Every aerial line, including its supports and all the structural parts and electrical appliances and devices belonging to or connected with the line, shall be duly and efficiently supervised and maintained as regards both electrical and mechanical conditions.

Unused aerial lines to be removed. 26. An aerial line shall not be permitted to remain erected after it has ceased to be used for the supply of energy, unless the Undertakers intend within a reasonable time again to take it into use.

Electric Lines other than Aerial Lines.

Construction of receptacles for electrical lines. 27. All conduits, pipes, casings and street boxes used as receptacles for electric lines shall be constructed of durable material, and where laid under carriage ways shall be of ample strength to prevent damage from heavy traffic; and reasonable means shall be taken by the Undertakers to prevent accumulation of gas in such receptacles.

Crossing pipes, &c. 28. Where any electric line crosses, or is in proximity to, any metallic substance, special precautions shall be taken by the Undertakers against the possibility of any electrical discharge to the metallic substance from the line or from any metal conduit pipe or casing enclosing the line.

Electric continuity of metal conduits, pipes or casing. 29. All metal conduits, pipes or casings containing any electric line shall be efficiently connected with earth, and shall be so jointed and connected across all street boxes and other openings as to make good electrical connection throughout their whole length.

Precautions against charging of short lengths of pipe, &c. 30. Where isolated lengths of metal conduit, pipe or casing are used for the protection of any electric line at road crossings or similar positions, special precautions shall be taken to prevent the possibility of any electrical charging thereof.

Precautions to be taken when bare conductors are used. 31. Where the conductors of electric lines placed in any conduit are not continuously covered with insulating material, they shall be secured in position, and no unfixed uninsulated material of a conducting nature shall be contained in the conduit. No such conductor shall be at a higher potential than 300 volts.

Adequate precautions shall also be taken to ensure that no accumulation of water shall take place in any part of the conduit, and to prevent any dangerous access of moisture to the conductors or the insulators.

In the case of any such electric lines laid in conduits after the date of these regulations, the insulators shall be so disposed that they can be readily inspected.

High-pressure lines laid above ground. 32. Every portion of any high-pressure electric line placed above the surface of the ground, or in any subway not in the sole occupation of the Undertakers, shall be completely enclosed either in a tube of highly insulating material embedded in brickwork, masonry, or cement concrete, or in strong metal casing efficiently connected with earth.

High-pressure lines laid in proximity to other electric lines or to the surface of the ground. 33. Where any high-pressure electric line is laid beneath the surface of the ground efficient means shall be taken to render it impossible that the surface of the ground or any neighbouring electric line or conductor shall become charged by leakage from the high-pressure electric line.

Street Boxes.

Street boxes. 34. In addition to the provisions contained in Regulation 27 as to the construction of receptacles for electric lines, the following regulations shall be observed with respect to the construction of street boxes:—

(*a*) The covers of all street boxes shall be so secured that they cannot be opened, except by means of a special appliance.

(*b*) The covers of all street boxes containing high-pressure apparatus other than cables shall be connected to strips of metal laid immediately underneath the adjacent roadway, and efficient means shall be taken to render it impossible that the covers or other exposed parts of these boxes, or any adjacent material forming the surface of the street, shall become electrically charged, whether by reason of leakage, defect, or otherwise.

(*c*) Where street boxes are used as transformer chambers, reasonable means shall be taken to prevent as far as possible any influx of water, either from the adjacent soil, or by means of pipes; and in the case of any such street box exceeding one cubic yard in capacity, ample provision shall be made, by ventilation or otherwise, for the immediate escape of any gas which may by accident have obtained access to the box, and for the prevention of danger from sparking.

Digitized by Google

(*d*) All street boxes shall be regularly inspected for the presence of gas, and if any influx or accumulation is discovered the Undertakers shall give immediate notice to the authority or company whose gas mains are laid in the neighbourhood of the street box.

TRANSFORMING STATIONS

Transforming stations. 35. Transforming stations, or points in a system of distribution in which a high-pressure supply is transformed for the purpose of supply to consumers, and which are not on the consumer's premises, shall be established in suitable places which are in sole the occupation and charge of the Undertakers.

CONSUMER'S PREMISES.

Responsibility of Undertakers for their lines, &c., on consumer's premises. 36. The Undertakers shall be responsible for all electric lines, fittings and apparatus belonging to them or under their control, which may be upon a consumer's premises, being maintained in a safe condition and in all respects fit for supplying energy.

Fire risks. 37. In delivering the energy to a consumer's terminals the Undertakers shall exercise all due precautions so as to avoid risk of causing fire on the premises.

Main fuses or disconnectors to be provided in a locked receptacle. 38. A suitable safety fuse or other automatic disconnector shall be inserted in each service line within a consumer's premises as close as possible to the point of entry, and contained within a suitable locked or sealed receptacle of fireproof construction, except in cases where the service line is protected by fuses in a street box.

Treatment of electric lines and apparatus on consumer's premises. 39. All electric lines and apparatus placed on a consumer's premises shall be highly insulated and thoroughly protected against injury to the insulation or access of moisture, and any metal forming part of the electric circuit shall not, unless efficiently connected with earth, be exposed so that it can be touched. All electric lines shall be so fixed and protected as to prevent the possibility of electrical discharge to any adjacent metallic substance.

Transformers and high-pressure apparatus to be enclosed in metal. 40. Where the general supply of energy is a high-pressure supply, and transforming apparatus is installed on a consumer's premises, the whole of the high-pressure service lines, conductors, and apparatus, including the transforming apparatus itself so far as they are on the consumer's premises, shall be completely enclosed in solid walls, or in strong metal casing efficiently connected with earth, and securely fastened throughout.

Connection to consumer not to be made where leakage would result. 41. The Undertakers shall not connect the wires and fittings on a consumer's premises with their mains unless they are reasonably satisfied that the connection would not cause a leakage from those wires and fittings exceeding one ten thousandth part of the maximum supply current to the premises; and where the Undertakers decline to make such connection they shall serve upon the consumer a notice stating their reasons for so declining.

Discontinuance of supply on discovery of leakage on consumer's premises. 42. If the Undertakers are reasonably satisfied, after making all proper examination by testing or otherwise, that a leakage exists at some part of a circuit of such extent as to be a source of danger, and that such leakage does not exist at any part of a circuit belonging to the Undertakers, then and in such case any officer of the Undertakers, duly authorised by them in writing, or, if the Undertakers so require, an electric inspector may, for the purpose of discovering whether the leakage exists at any part of a circuit within or upon any consumer's premises, by notice require the consumer at some reasonable time after the service of the notice to permit him to inspect and test the wires and fittings belonging to the consumer and forming part of the circuit.

In any case where the Undertakers require the services of an electric inspector under this regulation they shall pay him the prescribed fee.

If, on such testing, the officer or the electric inspector discovers a leakage from the consumer's wires exceeding one ten thousandth part of the maximum supply current to the premises, or if the consumer does not give all due facilities for inspection and testing, the Undertakers shall forthwith discontinue the supply of energy to the premises in question, giving immediate notice of the discontinuance to the consumer, and shall not recommence the supply until they are reasonably satisfied that the connection with earth has been removed. This regulation shall not affect any power contained in the Order or otherwise enabling the Undertakers to discontinue the supply.

Appeal to electric inspector. 43. If any consumer is dissatisfied with the action of the Undertakers in refusing to give or in discontinuing or in not recommencing the supply of energy to his premises, the wires and fittings of that consumer may, on his application and on payment of the prescribed fee, be tested for the existence of leakage by an electrical inspector.

This regulation shall be endorsed on every notice given under the provisions of either of the two last preceding regulations.

ARC LIGHTING.

Arc lamps to be guarded. 44. All arc lamps shall be so guarded as to prevent pieces of ignited carbon or broken glass falling from them, and shall not be used in situations where there is any danger of the presence of explosive dust or gas.

Height from ground. 45. Arc lamps used in any street for public lighting shall be so fixed as not to be in any part at a less height than 10ft. from the ground.

Cut-off switch. 46. Arc lamps used in any street for private lighting shall be fixed so as not to be in any part at a less height than 8ft. from the ground, and shall be so screened as to prevent risk of contact with persons. A cut-off switch, fixed in a suitable locked receptacle, shall be provided for every high-pressure arc lamp, and such switch shall be of such pattern and construction as will provide:—

(*a*) That the lamp can by its means be entirely disconnected from the supply circuit;

(*b*) That the switch itself can be safely operated in the dark without special precautions; and

(*c*) That there shall be no danger of any injurious electrical arcing, sparking, or heating being caused by the operation of the switch.

Penalties for default. 47. If the Undertakers make default in complying with any of the preceding regulations, they shall on conviction be liable to a penalty not exceeding £10 for every such default, and to a daily penalty not exceeding £10.

The recovery of a penalty under these regulations shall not affect the liability of the Undertakers to make compensation in respect of any damage or injury which may be caused by reason of the default.

B.—REGULATIONS FOR SECURING A PROPER AND SUFFICIENT SUPPLY OF ELECTRICAL ENERGY.

Notice of intention to supply through mains. 1. Forty-eight hours at least before the Undertakers are ready to commence to supply energy through any feeding, charging, or distributing main, they shall serve a notice upon the local authority of their intention to commence such supply.

Undertakers to provide constant supply. 2. From and after the time when the Undertakers commence to supply energy through any distributing main, they shall maintain a supply of sufficient power for the use of all the consumers for the time being entitled to be supplied from such main; and such supply shall, except so far as may be otherwise agreed upon from time to time between the local authority and the Undertakers, be constantly maintained. Provided that, for the purposes of testing, or for any other purposes connected with the efficient working of the undertaking, the authority by whom the electric inspector is appointed may give permission to the Undertakers to discontinue the supply at such intervals of time and for such periods as that authority may think expedient. When the supply is so discontinued, notice of such discontinuance, and of the probable duration thereof, shall be forthwith served upon the local authority.

Provisions as regards stoppage. 3. The system of distributing mains shall be so arranged that in case it becomes necessary to stop the supply through any portion of a main for more than one hour, for the purposes of repairs, or for any other reason, the stoppage of supply will in no case exceed in amount a maximum power of 200,000 watts, or extend to the premises of more than 80 consumers, and in the case of every stoppage for more than one hour reasonable notice shall be previously given by the Undertakers to every consumer affected thereby except in cases of emergency.

Pressure in mains during supply. 4. During the whole of the period when a supply of energy is required to be maintained by the Undertakers in the distributing mains under the Order and these regulations it shall be maintained at a constant pressure in these regulations termed the "standard pressure," but the standard pressure may be different for different portions of the distributing mains. Provided that the Undertakers shall be deemed to have complied with the requirements of this regulation so long as the pressure does not at any point vary more than 2 per cent. from the corresponding standard pressure in the case of a general supply at high pressure, or 3 per cent. in other cases, unless changes in pressure recur so frequently as to cause unsteadiness in the supply.

Fixing of standard pressure. 5. The standard pressure shall be fixed by the Undertakers, and notice of the amount of such standard pressure shall be given to the local authority before the Undertakers commence to supply energy to consumers, and such standard pressure shall not be altered except by permission of the local authority, and upon such terms and conditions as the local authority may impose, and after public notice has been given during a period of one month, in such manner as the local authority may require, of the intention of the Undertakers to apply for permission to alter the same. The Undertakers may appeal against any decision of the local authority under this regulation to the Board of Trade, whose decision shall be final.

Declared pressure at consumer's terminals. 6. Before commencing to give a supply of energy to any consumer, the Undertakers shall declare to such consumer the constant pressure at which they propose to supply energy at his terminals. The pressure so declared at any pair of consumer's terminals shall not at any time be altered or departed from except in consequence of any authorised alteration of the corresponding standard pressure. In the case of a transformation of energy on the consumer's premises, the Undertakers shall give the consumer the choice of a supply at either of two different pressures, one of which shall be approximately half the other, and in such case the pressure so chosen by the consumer shall be the declared constant pressure.

Provided that no change shall be made in the pressure of the supply to any premises which at the date of these regulations are supplied with energy by the Undertakers except with the consent of the consumer.

Variation of pressure at consumer's terminals. 7. The variation of pressure at any consumer's terminals shall not under any conditions of the supply which the consumer is entitled to receive, exceed 4 per cent. from the declared constant pressure.

Penalty for default. 8. If the Undertakers make default in complying with any of these regulations as to supply, they shall, subject to the provisions of the Order, be liable on conviction to a penalty not exceeding £5 for every such default, and to a daily penalty not exceeding £5.

ELECTRICAL PLANT IN THE UNITED STATES PRINTING OFFICE AT WASHINGTON.*

BY W. H. TAPLEY.

The plant consists of one 187½-kilowatt direct-connected generator and three 80-kilowatt belted generators, all of the most improved compound multipolar Westinghouse type. The 187½-kilowatt generator is directly connected with a Westinghouse compound condensing engine of 250 H.P. The two machines occupy a floor space of 21ft. by 7½ft. The 80-kilowatt generators are driven from a line shaft which is belted to a 250 H.P. compound condensing engine of the marine type. Friction clutch pulleys are used for driving these generators, thus giving the greatest flexibility to the plant by allowing the stopping of any one of the three generators while the others are in use. These, independent of the direct-connected generator, are capable of furnishing all the necessary power as well as light needed in the office in case a total breakdown of the direct-connected unit occurs. The total capacity of the four generators is 8,500 50-watt 16 c.p. incandescent lamps—more than sufficient for all lighting and power demands.

The peculiarities of the work of the office make necessary a sectional rather than a general system of electric lighting. With this end in view, the wiring has been done entirely on the "crib" system. This affords a uniform distribution of light throughout every division of the office, the rooms farthest away from the generator station being equally as well lighted as those near by. So perfect is this result that nowhere in the building does the variation from the switchboard to lamp exceed 2½ volts, nor is the variation in any one room ever more than one-fourth to one-half volt, no matter how many or how few lamps may be burning on the circuit. The capacity of all main trunk lines and feeders is so large that circuit regulators on the switchboard are not required.

To make up any loss from generator to lamp, the generators are overcompounded 1½ per cent., and their makers guarantee that no greater loss than 3 per cent. will occur from full to no load. Thus there will be a constant voltage at the lamps, whatever may be the existing conditions, insuring full candle-power and the long life of the lamps. We are thus able to get full benefit of the current generated, and not have a considerable portion of it consumed in rheostats that the system may be kept in balance.

The crib system has been extended to vertical mains as well, thus allowing the disconnecting of one side of the circuit without interrupting the service throughout that circuit while in use. The crib system of wiring not only increases the flexibility of the plant, but minimises the possibilities of interruption of work, and also equalises the distribution of current to the lighting mains.

In carrying out the instructions as to the application of electrical power, the office will use at present 70 Crocker-Wheeler electric motors of ⅛ H.P. to 30 H.P., aggregating 225 H.P.

To secure full protection against any possible interruption of work, except through a total failure of steam-power by accident, a suitable electrical switchboard of special design became necessary. This board is one of the largest and most complete in the country. It presents many peculiar features and fully meets the exactions of the service here, which will not permit interruptions during the sessions of Congress. The switchboard is divided into five panels—three for lighting and two for power. It is so constructed that an additional panel may be made without changing any of the connections. There are two sets of 'bus bars extending the entire length of the board—one for the use of the lighting circuits and the other for power circuits. By the use of a switch the two 'bus bars can be connected so as to make one continuous 'bus bar, and power and lighting circuits may be run together and from one generator should occasion therefor occur. Each generator is connected to the switchboard by a double-pole double-throw switch, thus allowing any generator to be used for power or lighting as occasion may require. Each feeder circuit is also controlled by a double-pole double-throw switch, giving every circuit throughout the building two sources of current and providing for an uninterrupted system either of light or power. Under normal conditions all lights will be run from one set of 'bus bars and the power circuits from the other, but when both power and lighting load become sufficiently small so that the combined demands of both are not in excess of the power of one 80-kilowatt generator, all work will be so divided by the switchboard as to make it possible to run everything from one generator. This board allows the changing from one generator to the other without any interruption to the service in the building or the running of the generators in multiple.

Each panel is provided with a standard Weston volt and ammeter. Each power circuit is supplied with a round pattern Weston ammeter. There is also connected to the lighting service a recording voltmeter. For testing insulation of each circuit there is a special reading in ohms marked on one of the voltmeters, thus enabling a daily log to be kept of the condition of each circuit of the plant. The measuring will be done by drop-of-potential method, and not only will each individual circuit be tested, but each leg of each circuit, a suitable switch being provided for the purpose.

More than 20 miles of wire of the best kind was used in the circuits, and during its erection full use was made of every precaution known that would render property and life more safe.

The insulation test of this entire system with all cut-outs in circuit will reach, under ordinary conditions, 8 megohms.

One of the special features of this electrical plant is the transmission of power by electricity. In all cases where it was possible so to do without interrupting work, we have connected motors direct to the machines themselves, doing away entirely with the use of belting and its attendant losses, disadvantages, and dangers. We find that the printing presses and some of the other large machines were never driven to their full capacity by belts, and that since they have been geared direct to the electric motors nearly double the amount of work has been done on some of them.

In gearing motors direct to printing presses we have not only secured the advantage of displacing belting, but enabled the pressman, by the use of a reversing regulator, to have absolute control of his press when making ready, and move the bed-plate forward or backward as desired, and without the help of a labourer. The speed of the press can also be regulated at will.

The two principal advantages of electric motive power over shafts and belts are the reduction of the friction load to a minimum and the independent working of each machine. Under the shaft-and-belt system the breaking of a belt often necessitated the shutting down of all the mechanical divisions.

To each motor is attached an automatic cut-off, so that accidents are not liable to occur through carelessness of employés. A still further safeguard is the automatic circuit-breaker, which prevents the overloading of motors.

In the erection of the plant every approved electrical device has been used. The short period during which the new plant has been in operation prevents full statements as to the amount of current and power consumed by each division of the office and the actual amount of power saved, as compared with the old system.

* Report by the Chief Electrician to the United States Public Printer.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *January 24, 1896.*

The Boynton Bicycle Railway.—For several years a company has been attempting to secure permission from the New York State Railroad Commissioners for the construction of a road on what is styled the "Boynton bicycle system." The peculiarity of the system consists in there being but a single rail underneath the car and a guiding rail overhead. Absurd claims have been made for the extraordinary efficiency of the system, supposed to follow from the peculiar construction described. The State Railroad Commissioners have refused to grant permission to build the road, for the reason, among others, that the system is such a special one that a special law will be necessary to authorise the Commissioners to take action on it.

A New Type of Steam Engine.—Mr. Elmer A. Sperry, one of the American pioneers in electric lighting, and more recently connected with the electric railway industry, had designed a peculiar engine, which permits double the number of revolutions to be made per stroke than with the usual type. The connecting rod of the engine, instead of connecting with the crank pin, reciprocates one member of a link motion, the second member of which connects with the usual engine connecting rod or the arm of a parallel motion similar to that used in old types of land engines. The link motion is of the usual form described in works on mechanism, which gives a reciprocating motion twice as rapid as that of the source. In the present instance, the shaft makes one revolution on the outstroke of the piston and another on the instroke; at the beginning of the first revolution the two arms of the link form an angle above the horizontal and at the end of the revolution a corresponding angle below the horizontal.

The Sprague Elevator.—At the meeting of the American Institute of Electrical Engineers on Wednesday of the present week, Mr. Frank J. Sprague read a Paper on Electric Elevators, describing more particularly the Sprague-Pratt

Digitized by Google

elevator and the large plant built for its manufacture in the neighbourhood of New York. The Sprague-Pratt elevator is of the horizonal multiple-sheave type, with a travelling cross-head on a nut driven by a screw revolved by an electric motor directly connected and controlled by a small auxiliary motor and rheostat. The feature of most interest is the nut, the only points of contact between which and the threads of the screw being by a chain of balls which occupy a number of threads and enter and leave the end of the nut through tubes which are connected together so as to make a continuous conduit. The longitudinal thrust at the motor end of the screw is also taken on balls, and the sheaves are carried on ball or roller bearings. The controlling apparatus is actuated by a small motor of about one-sixth of a horse-power, which is manipulated from the car. The controller rheostat is made up of cast-iron resistances, which Mr. Sprague was the first to use commercially in this country. The resistance is about 60 times that of copper, and in working a very high temperature may be permitted.

CORRESPONDENCE.

RÖNTGEN RAYS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Those of your readers who are making experiments on Röntgen's rays may perhaps be interested in a method of testing their presence which is more delicate and expeditious than a photographic plate, and also more easily adapted to quantitative measurements. It is simply a charged insulated metal plate. I have found that when this is exposed to Röntgen's rays it rapidly loses its charge, and the test is so delicate that I have by this means been able to detect the rays after their passage through a zinc plate ¼in. thick. The leakage caused by these rays differs materially from that investigated by Elster and Geitel and due to ultra-violet light. In the first place the Röntgen rays discharge positive as well as negative electricity, and secondly, the leakage goes on even when the electrified plate is embedded in paraffin, ebonite, mica, sulphur, &c. This shows that *all substances through which the Röntgen rays are passing become for the time conductors of electricity*. This result seems to me very suggestive both as to the nature of the rays and also of the conduction through the insulator.—Yours, &c.,

J. J. THOMSON.

Cavendish Laboratory, Cambridge, February 4, 1896.

DR. HOPKINSON'S PRESIDENTIAL ADDRESS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Whatever may be said of the subject-matter of the above, some of the terms employed are decidedly old-fashioned and unsatisfactory. For instance, positive and negative electricity, frictional electricity, voltaic cell, galvanism, and loadstone (*sic*). The term galvanic is repeated *ad nauseam*, as in galvanic cell, galvanic battery, galvanic element, galvanic circuit, galvanic current, galvanic agency and galvanic effects.

Bearing in mind that the memory of Galvani and of Volta has been perpetuated in "galvanometer" and "volt," there is not the slightest need for the use of voltaic or galvanic, which terms are, in my mind, quite meaningless. To take a common example, apart from the above, why should voltaic arc so often be used? Why voltaic and not davaic or davic? Davy was the discoverer, not Volta. Electric arc, I take it, is the best term.—Yours, &c.,

W. PERREN MAYCOCK.

Croydon, February 1, 1896.

COLONIAL ELECTRICAL ENGINEERING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of the 31st ult. you make some rather sarcastic remarks on the design of the Melbourne Municipal Lighting Station, and, whilst not wholly agreeing with your remarks, they might serve as the text for an interesting article on "Colonial Engineering."

As to countershafting, that is almost invariable, and the colonial mind in 1892, when I left Sydney, had hardly got to the point of considering direct driving, there being only one such plant in Sydney to my knowledge—viz., at the Hotel Métropole—a duplicated combined Willans-Elwell-Parker set, 24 kilowatts.

At the time the Melbourne station was projected and designed, it must be remembered that there was only one practicable system of street lighting—high tension series, and the largest practicable arc-lighting machine was 60 lights, and it is not quite easy to see how such a number of machines could be run off the engines there laid down with the same convenience direct as off the countershaft. As regards the economy of the large engine units adopted, the load is necessarily uniform, and it is easier to build an economical (fuel) engine of large than small size. For the same reason the loss in running the countershaft is of less consequence than with a widely-varying load in proportion to the output.

There are further reasons for the choice of a large engine unit.

1st. Owing to the high price of labour in Victoria maintained by the Engineers' Society by the aid of a prohibitive protective Customs duty, the cost of building a large engine is substantially less per horse-power than a small engine.

2nd. By Victorian laws every engine-driver must have a certificate of competency (?) issued by an examining Board. By reducing the number of engines a reduction is made in the number of such certificated men, who might at any time combine and cause trouble to their employers. I may say that by the regulations issued a boy of 17 could *legally* be competent to drive a second-class engine after twelve months' experience, or one-fifteenth of my own, and before I could obtain such a certificate I should have to serve a year *under* that boy. It is needless to say that such a certificate is of no value whatever as a proof of competency, and is merely worked as a trades-union dodge, as was evidently the object of Mr. W. Allan's Bill, which failed to pass in the last Parliament, and it is my practical experience of the working of such a law that causes me to object to it on principle.

I think you will agree that the foregoing reasons are sufficient to show that Mr. Arnot was well advised in his design. If you want more you have it in the fact that any of our modern London stations would be unbearable in a Melbourne summer; 110deg. in the shade by day and 90deg. at night for a month on end is not very remarkable in Melbourne in January.

I am not personally acquainted with Mr. Arnot, though I have spoken to him more than once, and think that he is quite capable of intelligently weighing local conditions, and I write this notwithstanding that I am no lover of the Cornstalk, and would be glad to see him politically independent of this country.

As showing the sort of work that passes muster in "colonial engineering," I may give two instances:—

1. An 8-10in. countershaft in a Melbourne tramway engine house was running with about 1in. of wobble on it, and the nuts had to be kept off the pedestal cap. I saw this myself, and was told that the shaft was bent in slinging and had never been straightened.

2. A small screw steamer built on the Yarra; when steam was turned on the engines spouted tallow at every joint. I had this on good authority.

I was once employed to take charge of and repair a small central station in New South Wales, which I still dream of when I have a nightmare, and if you can spare the space a description may amuse your readers.

The "station" consisted of a corrugated iron shed for the "machinery" about 30ft. × 10ft., with a lean-to for a coal store. In one corner was a recess, which was the "resident engineer's" quarters, and contained a rectangular frame with three old sugar bags nailed on to it and a filthy blanket (my quarters were not there) which I did *not* use. The plant consisted of—

(1) A Robey boiler (loco. type), supposed to be up to 12 H.P., which was fed (by a leaky pump on the engine) with the drainings off a road near by. The boiler, when I saw it, had been working eight months, and I have reason to believe that it had never been washed out since it was started. There

Digitized by Google

were two safety (?) valves, one a spring balance, which was set up "as far as it would go." I may say that there was no danger, since the valve leaked a trifle. The other was a lock-up valve, but the padlock had been broken off, and the valve screwed hard down. The "central station" was not "lock up," and when I asked the driver—who informed me that he was a "born and bred millwright"—for an explanation, he said that "the children had done it!" On that morning I had taken nine shovels of damp ashes out of the smoke box (full size, not an ordinary fire shovel). The "children" had evidently *not* done that. At full load it was customary to use a supplementary lever on the lever of the safety valve—the "pricker" was mostly used for this with a brick on the end of it. The last I heard of the place was that a "bucket of bricks" was substituted for the single brick.

The chimney was about 12ft. high, supported mainly by the roof, but assisted by four stays 16 B.W.G., twisted round wire nails in the eaves of the building. The engine exhaust was turned into the chimney—eccentrically, spiral draught was considered desirable for some reason. My successor hammered the pipe flat and tried a fan-shaped blast, and said the draught was much improved thereby.

(2) A Robey inverted engine with automatic expansion gear, and rated at 20 I.H.P. at 80lb. steam. Speed, nominally 150, but varied with various conditions from 80 to 200 ("shorts" excluded). The most prominent feature about the engine was the exhaust, which was nearly continuous, little or no "beat" being heard except when a "short" happened. (N.B.—It is within my own knowledge that the "children" *were* responsible for a good many of these.) Every facility was given for ashes and dust to blow over the working parts—I presume to allow them to grind to a fit. A countershaft was provided, from which the "generator"—a "Manchester" 100-lighter—was driven. There was no switchboard, the "instruments" (main switch and fuse) being spiked to the frame of the shed, the voltmeter being usually hung on a nail.

The fuse consisted of two brass pegs with copper bell wire wrapped round them, the total section being about three times that of the mains; this, however, was not dangerous, as the engine warned the driver of a "short" by slowing down. The principal use of the "main switch" was to signal to the consumers when to light their *oil* lamps, the recognised signal being three blinks. I may say that there was a supplementary boiler feed pump—a small "Blake." It failed, however, to work properly on high pressure, and was used to deliver water into a small water tank over the boiler. *Leather* valves are hardly adapted for boiler feed.

(3) The mains were of soft drawn bare copper, so that they should "give" rather than overstrain the supports. They were calculated at 1,000 amperes per square inch. I understood that the consulting engineer had spent two months in England, and had discovered the proper method of calculating street mains. The station was at one end of the town, and the bulk of the lighting at the other end. This rather disturbed the calculator, but he reflected that the only result would be an excessive drop of pressure, and as the lamps had to be bought second-hand whenever a job lot was run against, this would give an opportunity of "grading them." It was rather awkward, however, when lamps ran short, and 110-volt lamps had to be run on 70-volt circuits, and the public grumbled if a 50 volt had been previously used. "Earths" were not considered of any consequence, and if a wire came down the first passer-by would make it fast to the nearest fence. The street lighting was by 30 16 c.p. lamps on brackets on the poles. Drip-loops on the lamp leads were evidently thought inadvisable, and provision was therefore made for the rain to run down the bracket to the lamp socket. I may say that near the "station" the lamps were usually like moons, and at the farthest circuit you had to take a lantern to find them after dark.

The repair plant and spare gear was eminently simple. Here is a list as far as I can remember it: One tube brush (*non est*—the "children" had stolen it), one fire shovel (broken) one rusty vice, one cold chisel (the smith failed to harden it), half-dozen files (all worn out and mostly broken), half a gimlet, half a file handle, one ¾in. tube cutter (with the cutter broken) one broken hammer shaft, a few pieces of insulated wire, of various makes and kinds, lengths from 1ft. to 20 yards; an assortment of broken lamp holders, &c., 50ft. of redwood casing and covering (this had the dry rot).

I may say that I was on the job for exactly 10 days. I found, however, that none of my recommendations were likely to be carried out, not even the cheapest of them, and I therefore gave it up. This job is (or *was*) at Moss Vale, on the Southern New South Wales Railway line to Melbourne, &c. The description is absolutely true. I could give a few details of some other jobs that would no doubt amuse you.—Yours, &c.,

GEO. F. PARDOE.

81, Harrow-road, Paddington, February 3, 1896.

LEGAL INTELLIGENCE.

Lazare Weiller and Co. v. Bolton and Co.

On Wednesday, in the Queen's Bench Division, Mr. Justice Mathew heard this action, which was for damages for breach of an agreement, dated November 28, 1894, the breach alleged being refusal by the defendants to accept and pay for goods delivered pursuant to the agreement. The case was opened by Mr. Bigham, Q.C., for the plaintiffs, and turned principally on the correspondence and the circumstances preceding and subsequent to the date of the agreement. The plaintiffs are manufacturers of copper wire at Angoulême, France, with an office in Paris, and the defendants are manufacturers of the same description of goods at Oakamoor, Staffs. It was alleged by defendants that the contract had been made by misrepresentation, and they claimed to have it rescinded or reformed. Messrs. Lazare and Weiller made wire for telephonic purposes, and at the end of 1893 established large works at Angoulême, which enabled them to compete in English markets against English makers so successfully that in March, 1894, Messrs. Bolton put themselves in communication with plaintiffs, who had started an agency in England, with the object of inducing them to join a ring or pool to be formed in this country by the different makers, so as to fix a price in England which would be profitable to the manufacturers. Negotiations went on for some time, and M. Weiller eventually replied that the plaintiffs' firm would not join a ring or pool, but were ready to make a contract with Messrs. Bolton under which they were to take certain quantities of the plaintiffs' manufactured goods per month for a period of five years, the plaintiffs undertaking not to compete with English manufacturers in the English market.

The JUDGE: That was to sell exclusively to the defendants?—Yes.

The defendants replied that the quantities stipulated for were too large, but that if 50 tons a month would do it they would make a contract. On November 17th, however, Mr. Rathbone, one of the partners in Messrs. Bolton's firm, called upon M. Weiller in Paris, and again suggested that a pool should be formed, but M. Weiller repeated his refusal, and said if he was to be bought out of the English markets it must be by his selling 300 tons a month. Mr. Rathbone asked him to hold his hand for the time, not to take orders in England till he (Mr. Rathbone) returned to England. Later on, after further correspondence, the plaintiffs wrote agreeing to accept the following terms: The defendants to take monthly 125 tons of copper rods at £11 net over and above the price of Chili bars, and 75 tons of wire at £15 net over and above the price of Chili bars. M. Weiller visited Mr. Bolton at Oakamoor to complete the contract on November 27th. One of the alleged misrepresentations relied upon by the defendants was that M. Weiller said the plaintiffs' sales in England amounted to 200 tons a month. It was suggested that it was because of this and other representations the contract had been made; whereas it was contended by the plaintiffs that the first suggestion of 200 tons per month was contained in the defendants' own letter. On November 28th the contract was signed, the effect of which was that the plaintiffs were to be bought out of the English markets, on condition of the defendants taking 200 tons a month from them; or, if the plaintiffs sold in the English markets, it was only to be at such prices as the defendants permitted, and to the extent that the plaintiffs did sell in the English markets Messrs. Bolton were to be relieved of their obligation to take goods from the plaintiffs under the contract. During the discussion of the contract, Mr. Bolton had shown himself fidgetty about American and German competition, and no doubt M. Weiller said he would do his best to assist the English manufacturers. After leaving, M. Weiller spontaneously wrote:—"I desire particularly to say to you that if such a case presented itself, then it would be necessary to carry the contest either against the importation or invasion of American products, or against the opposition—the unforeseen national opposition—which might show itself in any important degree, you would find me ready to lend you my assistance in order to organise the contest against such an opposition. We should have in each particular case to conform ourselves to the circumstances in order to organise with you the contest, whether by a provisional lowering of general prices, or of prices of contracts, or by the delivery by us of a part of the wire at the price of the opposition, or by other means which we should judge efficacious. If the case arises, I wish to add this declaration before saying 'Good-bye' to you, so that you may know well that the opponent of yesterday has now become the collaborator of to-day." The defendants now contended that this spontaneous communication was a part of the contract, and that it nullified the contract. If that letter

Digitized by Google

was part of the contract, why was it not, Mr. Bigham urged, included in the contract? It was no part of the contract, and was a mere spontaneous expression of M. Weiller's readiness to assist in meeting German and American competition.

The Judge asked what was the price at which the rods were to be delivered.

Sir E. Clarke, for the defendants, said the whole contract over the period it had to run was for £600,000.

M. Weiller gave evidence in support of the foregoing statement, and denied that he had made the representation that plaintiffs' business in the English markets was increasing. But if he had made the statement it would have been true. Nor had he represented that their sales were 200 tons a month. He had written the letter quoted when inspired by grateful sentiments in regard to Mr. Bolton's charming hospitality. It was in his own language, had no reference to the contract, and was quite spontaneous.

The case was adjourned to this day (Friday).

Electrical Installation Company v. Francis and Spilsbury.

This case was heard on Friday last at the Westminster County Court. The plaintiffs are electrical engineers in business at Victoria-street, Westminster, and sued the defendants, who are dealers in electrical appliances at Queen Victoria-street, London, to recover the sum of £6 odd alleged to have been overpaid in respect of a quantity of electric lamps supplied to order. The plaintiffs' case was that in July last an order was sent to the defendants to supply several hundred lamps of various patterns. The goods were delivered in due course, but upon the case being opened and unpacked it was found that there was a deficiency in the number of lamps to the extent of about 75. The defendants were written to on the subject, but in the meantime they were pressing for payment of their account, and, by a mistake, a cheque was sent for the full amount of their claim. Several applications were subsequently made to complete the order but declined, and consequently the plaintiffs had to go direct to the Edison and Swan Company for the goods. The effect of that had been that the plaintiffs had had to pay twice over for the 75 lamps in question, and they now sued the defendants to recover the cost.

For the defence Mr. FRANCIS was called, and said his firm acted as agents for the Edison and Swan Company, and the order in question was in due course sent on to them. He had every reason to believe the Company sent on the correct number of lamps, and that was why he disputed liability in this case.

Two witnesses were called from Messrs. Edison and Swan, and both of them were able to say positively that the whole of the lamps included in the plaintiff's order were duly packed and dispatched.

Mr. LUMLEY SMITH, Q.C. (the judge), in giving judgment, said it was extremely difficult in cases of this kind to say who was right, but, under the circumstances, he thought it was probable that a mistake had been made in the packing at the premises of the Edison and Swan Company, and judgment would be for the plaintiff for the amount claimed, with costs.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

SPECIAL NOTICE.—The 1896 (fourteenth annual) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK will be ready next week. The published price of the Directory and Handbook is 7s. 6d., post free 8s. 3d., abroad 9s. The book is greatly enlarged.

NEW BOOKS AND EDITIONS.

The following New Books and Editions of "THE ELECTRICIAN" SERIES *can be obtained of the Booksellers or direct from the Publishing Offices:—*

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett *(now ready)*. Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"THE WORK OF HERTZ."—By Dr. O. J. Lodge, with many origina illustrations, price 2s. 6d. nett, is now ready.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

"ELECTRIC MOTIVE POWER."—A new work, by Mr. Albion T. Snell with this title, is now ready, containing the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d. post free (abroad 11s.).

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by Messrs. W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—By Mr. F. Marten Weymouth is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.—The fourteenth annual issue of this publication will be ready next week, and would have been published a few days earlier but that it was the desire of the Publisher to include the revised Board of Trade model regulations. These were only issued yesterday (Thursday), and we hope to have the Directory and Handbook ready for subscribers by Wednesday next, so that it will be seen that no time has been lost. The Directory section of the book is equally up to date, and will be found to contain corrections and new names and addresses complete up to the 5th of the current month.

TENDERS INVITED.—The Vestry of St. John, Hampstead, require tenders for works and materials for one or three years for (1) coals and coke, (2) oils for machinery at electric lighting station, (3) tools, implements and other electrical engineers' stores, (4) carbons, lamps and other stores for electric lighting station, (5) removing ashes from electric lighting station. Some further particulars are given in our advertisement columns. Tenders must be sent in to Mr. Arthur P. Johnson, Vestry Clerk, by 4 p.m. of February 12th.

——— The Belper Gas and Coke Company (Limited) contemplate putting down a plant for electric lighting. Communications are to be sent to the Managing Director of the Company, at Belper.

——— The Harrogate Corporation invite tenders for the erection of an electricity generating station and chimney shaft. Tenders, by 11 a.m. on Monday next, to Mr. S. Stead, Borough Surveyor, Municipal Offices, Harrogate.

——— The Municipal Authorities of Manuel (Valencia) invite tenders for the concession for the electric lighting of the town for 15 years. Tenders to El Secretario del Ayuntamiento, Manuel (Valencia), Spain, by the 11th inst.

——— The Breslau Direction of the Prussian State Railways require tenders for the supply of a quantity of porcelain insulators and telegraph wire. Tenders to the Königliche Eisenbahn Direction, Oberschlesischen Bahnhof 21-23, Breslau, by the 10th inst.

——— The Municipal Authorities of Santa Coloma de Farnés (Barcelona) invite tenders for the concession for the electric lighting of the streets, and also for the lighting of the municipal building. Tenders to El Ayuntamiento, Santa Coloma de Farnés (Barcelona), Spain.

——— The Municipal Authorities of Béziers are inviting tenders for the concession for the construction and operation of about 8 kilometres of electric tramways in the town. Tenders to La Mairie, Béziers (Herault), France, by the 15th inst.

——— The Committee of the West Riding Asylum, Menston, require tenders for the supply and erection of telephones and electric bells for the new buildings and houses on the estate. Specifications can be obtained at the County Surveyor's Office, Wakefield, or at the offices of the Clerk of the Works, at the Asylum. Tenders to Mr. J. Vickers Edwards, County Surveyor, Wakefield, by the 17th inst.

——— The Paving Committee of the County Borough of Rochdale require tenders for the electric lighting plant required at the Works, Rochmills. Specifications, &c., can be obtained at the offices of the Borough Surveyor, and tenders must be sent in to the Town Clerk not later than noon on Wednesday next.

TENDERS ACCEPTED.—The Bolton Town Council have decided to accept the joint tender of Messrs. Hick, Hargreaves and Co. (Limited) and S. Z. de Ferranti (Limited) for a 200-kilowatt steam alternator.

——— The Bradford Corporation have placed an order for two high-speed 600 H.P. steam engines, for their new electricity works, with Messrs. G. E. Belliss and Co. (Limited), of Ledsam-street Works, Birmingham.

——— At the meeting of the Preston Town Council last week it was decided to accept the tender of the National Electric Supply Company for the erection of and supply of electric current to 300 incandescents, for lighting Church-street and Friargate.

——— The Deacons of Zion Methodist Chapel, Lindley, Huddersfield, have accepted the tender of Messrs. J. H. Holmes and Co., of Newcastle, for the electric lighting of the chapel.

——— The Shoreditch Vestry have accepted the tender of Messrs. Atherton and Dolman, of Ellerthorpe-street, Poplar, London, E., for the erection of dust destructor, engine house and offices, &c., in connection with their electric lighting and dust destructor scheme, for £8,535.

Digitized by Google

TENDERS ACCEPTED.—The tender of Mr. Bloomfield, of Maidenhead, has been accepted by the authorities for electric bell fitting at the School for Technical Instruction, Maidenhead, for the sum of £5. 10s. 6d. Two other tenders were sent in.

LIGHTING SCHEMES INVITED.—It will be seen by our advertisement columns that the Urban District Council of Eston, Middlesboro', invite schemes for lighting the district by electricity. A plan of the district can be seen and particulars obtained on application to Mr. F. W. Stainthorpe, A.M.I.C.E., District Surveyor, Grangetown, Yorkshire, to whom schemes must be sent in not later than May 1st next. Mr. Jno. T. Belk is clerk to the Council.

SALE BY AUCTION.—Messrs. Hepper and Sons have received instructions from the Corporate Property Committee of the Leeds City Council to sell by auction at the Municipal Buildings, Leeds, on Thursday, February 13th, at two o'clock, a large quantity of electric lighting plant, including engines by Willans and Robinson and Crossley, boilers by McLaren, dynamos by Mather and Platt and Paterson and Cooper, E.P.S. accumulators, and a quantity of apparatus and instruments, forming the complete installation which was some time ago erected at the Municipal Buildings, and which is now dispensed with as current is taken from the local Electric Supply Company's mains. Some further particulars are given in our advertisement columns. Catalogues are now ready, and may be obtained of the auctioneers, East-parade, Leeds.

VACANT APPOINTMENT.—As stated in our last issue, the Corporation of Edinburgh are now prepared to receive applications for the post of resident engineer for their central electric light station, in succession to Mr. E. W. Monkhouse. Some further particulars are given in our advertisement columns, and applications have to be sent in to Mr. T. Hunter, W.S., Town Clerk, City-chambers, Edinburgh, by the 17th inst.

FAILURE.—A receiving order has been made against G. J. Reakes, electrical engineer, of Shrewsbury. The examination is to take place at the Shire Hall, Shrewsbury, on 11th inst., at 10:30, and the first meeting at the office of the Official Receiver on the 13th inst. at 11.30.

LIQUIDATIONS.—In a Trade Note in our last issue it was announced that a meeting of creditors of J. C. Howell, Limited (in liquidation), would be held on Wednesday last. The meeting was duly held, and Mr. S. F. Isitt was able to announce that the liabilities since the liquidation commenced had been reduced from £4,236. 16s. 3d. to about £1,610. Mr. Howell made a statement as to the value of the outstanding assets, and said they would produce ample funds to pay all debts in full. The following resolution was then agreed to by those present (representing £1,070 of the outstanding liabilities):—

"That the liquidator be authorised to hand all the remaining assets of the Company to Mr. Howell forthwith, upon receiving from him an engagement in writing to pay or satisfy all the liabilities of the Company within one month from this date" (February 6th).

Mr. Howell, at the close of the meeting, gave Mr. Isitt the necessary undertaking, and the securities in question were thereupon handed over to him.

——— At a meeting of the proprietors of the Acme and Immisch Electric Works (Limited), of Ferdinand-street, Chalk Farm, London, N.W., on December 30th, it was decided to wind up the Company voluntarily. This resolution was confirmed on January 15th, when Messrs. E. Wilding and James Gray were appointed liquidators.

——— A meeting will be held at 27A, Sackville-street, London, W., on March 3rd, at 12 o'clock, for the purpose of receiving an account of the winding up of the Foreign Electric Date and Time Stamp Company (Limited).

RELEASE OF TRUSTEE.—Notice is given of the release of the trustee (the Official Receiver, Mr. E. G. Clarke, Bristol), in the failure of John H. Hale, india-rubber merchant and electrician, of Old Vicarage, Stanton Drew, Somerset, and 25, St. Stephen-street, Bristol.

THE "ENGINEERING MAGAZINE."—The February issue of this excellent magazine is now ready, and fully maintains its high standard of excellence. The articles in the present issue include: "Jingoism, or War upon Domestic Industry," by Edward Atkinson; "The Trade and Industry of South America," by Emilio M. Amores; "Gold Mining in the Southern States." by H. B. C. Nitze; "The Commercial Exploitation of Electricity," by Burton E. Greene; "Limits and Possibilities of the Gas Engine," by George Richmond; "The Railroad Accident and Emergency Service," by W. L. Derr; "Locating a Public Water Supply," by Daniel W. Mead; "Architectural Sculpture in the United States," by Russell Sturgis; "The Free Port of Copenhagen," by P. Vedel; "The Stubborn Opposition to Inventions," by W. C. Dodge. The usual exhaustive review of the World's Press is also given. This number, as well as all the back numbers, may be obtained at the offices of the European edition, 1, 2 and 3 Salisbury-court, Fleet-street, London, E.C.

CASSIER'S MAGAZINE.—The contents of this popular magazine for February include articles on "Modern Shipbuilding Tools," "A Steam Plant for a small Electric Light and Power Station," "Saving Fuel in a Large Oil Refinery," "Long-Distance Electric Power Transmission in the United States," "Water Power," "Carborundum," and other articles of interest to many of our readers. Many of the writers are well-known American engineers.

"THE NEW LIGHT."—Under this title the publishers of the *Photogram* have just issued a special edition for February, containing a translation of Prof. Röntgen's original Paper on "The New Kind of Rays," together with contributions on the subject by several other observers. The pamphlet is well printed, nicely illustrated, and well calculated to meet the popular demand just now for information on this phenomenon. The publishers are Dawbarn and Ward, Farringdon-avenue, E.C., and the price 3d.

DYNAMO AND MOTOR PRICE LIST.—We have received from the Electrical Company (Limited) of 122 and 124, Charing-cross-road, W.C., a copy of their 1896 price list for continuous and alternating current dynamos and motors, and a few accessories. Machines of the first-named kind are made from 1 H.P. upwards. The smaller machines are of the bipolar type, the larger being multipolar machines. Prices for starting and regulating switches are given, as also for equalisers, which are required when a three-wire system is fed from one dynamo without accumulators. In the alternating current section of the catalogue particulars are given of single and three-phase generators, motors, transformers and starting and regulating devices. The catalogue is well compiled and illustrated, and contains, besides the various prices, a quantity of useful information. The dimensions are given in metric measurements and the weights in kilogrammes.

ABERDEEN.—The question of payment of a royalty for the use of the three-wire system by the Corporation was discussed at its last meeting, the subject being taken in consequence of the application of the owners of the patents for an extension of time. It was pointed out that under present arrangements the royalty would entail an annual charge of £250, which will be largely increased when the Corporation's electric lighting system is extended. It was decided to call a special meeting of the Council to consider the matter, it being stated that the Corporations of Edinburgh, Glasgow and Belfast had invited Aberdeen to join them in opposing the application for extension of time.

ALTRINCHAM.—At the last meeting of the Urban District Council the question of the application by the Altrincham Electric Supply Limited for lighting the township of Ashton-on-Mersey was discussed, and it was decided that steps be taken to protect the interests of the Council in the matter.

BELFAST.—At the last meeting of the Belfast Corporation the report of the Council in Committee on the Tramways Bill of the Belfast Street Tramways Company, to enable the Company to introduce a system of electrical or other mechanical traction on their lines was considered and discussed. The Committee reported that as such powers would seriously affect the interests of the ratepayers they had instructed the Town Clerk to prepare and lodge a petition against the Bill. The Committee's report further recommended that a special committee be appointed to visit some of the chief towns and cities on the Continent where electric traction is employed in order to obtain full particulars of the various systems and to present a report thereon to the Council. After discussion the Committee's report was adopted.

BIRMINGHAM.—The Town Council have decided by 36 votes to 16 to endorse the recommendations of the Works Committee to allow the Birmingham Central Tramways Company to introduce the overhead system of electric traction on their Nechelles Tramway route.

BOLTON.—The Town Council have appointed the borough surveyor and the electrical engineer to prepare and present a report upon (1) the probable cost of the introduction of the overhead electric traction system on the local tramways; (2) the comparative cost of horse and electric traction, (3) the financial position of the Corporation with regard to the sinking fund on the first cost of the permanent way of the tramways, and the additional cost of the overhead system; (4) the amount of the annual payment for sinking fund and interest, and the rent the Corporation would have to receive in order to make the new system a financial success; and finally as to the general advantages of a system of electric over horse traction.

BOYLE (IRELAND).—Messrs. Curtis Bros., of Dublin, recently submitted a scheme for lighting the principal streets of the town electrically. This scheme was considered at the last meeting of the Town Commissioners, and provided for the erection of six 2,000 c.p. arcs, 40 32 c.p. incandescents, and for the supply of about 500 16 c.p. lamps for private lighting. The cost of the necessary plant was put at £2,405, and the approximate maintenance cost at £200 per annum. After some discussion the Commissioners decided to postpone the matter for the present.

Digitized by Google

COLCHESTER.—The Town Council have appointed a special Electric Lighting Committee.

CORK.—The City Council have now decided to ask Mr. E. Manville to prepare a report on the electric lighting of the city.

DERBY.—The Town Council have increased the salary of their electrical engineer (Mr. J. E. Stewart) from £250 to £300 per annum. At the last meeting of the Council the chairman of the Electric Lighting Committee (Alderman Leech) gave a lengthy explanation of the expenditure of the Committee, and £5,600 was voted for electric light purposes during the coming year.

DOUGLAS (ISLE OF MAN).—Much interest is evinced by prominent men at Douglas in the proposal now before the Douglas City Council to light the town by electricity. The disputants for and against the introduction of the electric light, so far, are Mr. G. Gillmore, electrician and local manager of the National Telephone Company, and Mr. E. Berry. Mr. Gillmore is opposed to the introduction of the electric light, at any rate for the present. Mr. Berry, on the contrary, advocates the immediate introduction of the light, and in reply to assertions that the cost of electric lighting is three times that of gas adduces Mr. Trotter's famous Hastings report, which appeared in our columns in December last. This report is certainly a hard nut for gas enthusiasts to crack, and Mr. Berry appears so far to have considerably the best of the argument. The discussion is not devoid of humour, and one gentleman, Mr. Clucas, a candidate for local honours, provides the droll element by an original but not particularly lucid manipulation of a few figures he has worked out, that the cost of the electric lighting of the town of Douglas would work out at £14,074. 1s. 9d. per annum against the charge of £1,030, the present cost of the gas, but then Mr. Clucas is a candidate for Council.

DUNDEE.—A report has been presented to the City Council by Mr. W. Brownlee, and was discussed at the meeting on Tuesday. The report states that on the 21st ult. two accidents occurred at the electric lighting station, causing the suspension of the supply of current for five hours. About 10 a.m. the steam pipe supplying the pump engine burst, rendering the engine useless. The injector in the boiler house was then used for feeding the boilers until 5:45 p.m., when the plug of the overflow valve gave way, stopping the further supply of water to the boilers. The accumulator battery was then brought into requisition, and kept up the supply of current for about half-an-hour, after which, the water in the boilers having fallen to the lowest level consistent with safety, the fires had to be drawn. Repairs were effected as quickly as possible, and current was again available at 11:15 p.m. The Board of Trade Surveyor has investigated the cause of the accident, but no report is yet to hand. Mr. Brownlee proposes that, in order to avoid similar accidents in future, a third means of feeding the boilers should be provided, preferably in the shape of an electrically-driven pump. Certain improvements suggested by Messrs. Carmichael and Co., who carried out some of the repairs, have been adopted.

ECCLES.—At the last meeting of the Town Council, the Town Hall and Electric Lighting Committee recommended that application be made to the Local Government Board for sanction to borrow the sum of £20,000 for electric lighting purposes, and after considerable discussion this recommendation was carried by the casting vote of the Mayor.

EDINBURGH.—At the last meeting of the Town Council the Plans and Works Committee recommended that the electric light be installed in the police cells at an estimated cost of about £180. Mr. Cranston moved disapproval of the minutes, but, as there was no seconder, the motion fell through.

HALIFAX.—At the meeting of the Markets Committee of the City Council last week the scheme for the electric lighting of the new markets was discussed and finally approved. The markets are to be lighted by means of incandescent lamps.——The electric light has just been introduced into the Theatre Royal, Halifax.

HULL.—At the last meeting of the Electric Lighting Committee the accounts of the department for the past year were submitted. Mr. Holder, the chairman, in commenting upon the success of the undertaking, said that they had sold 246,277 units of electric current against 163,857 units in 1894, an increase of 82,420. Up to the present their total capital expenditure amounted to £45,429. The revenue from all sources during the year had been £6,532, out of which they had paid £1,250 for interest and £1,113 had been set aside for sinking fund purposes. After paying all working expenses, &c., they had a balance of £1,263 profit, or sufficient to pay 9 per cent. interest on the capital expenditure. The number of customers had increased from 271 in 1894 to 399 in 1895, while some of their old customers had been so satisfied with the light that they had extended it to other parts of their premises. Mr. Holder also complimented the late and present engineers, Messrs. Gibbings and Barnard, upon the success of the undertaking, and said there were very few stations in England that could boast of such a low cost of production per unit. If the demand for current continued to increase at the present rate, he thought that if they were to keep within the limits of safety they would have to refuse to take any more customers at the latter part of next winter. Their station would not permit enlargement of their area so profitably as would the laying of a station or stations in outlying districts. The maximum output of the engines when working at full load was 5,950 amperes. This year their largest output was 3,340 amperes. The stand-by in case of the breakdown of one engine should never be less than their largest amount of production—viz., 1,600 amperes—and they could, therefore, only supply a maximum of 4,350 amperes. During the last year the increased customers applied for 1,629 amperes, and the corresponding increase during the present year would make their maximum output 4,969 amperes; he thought, therefore, that the Committee would have to decide upon some means of enlarging their works. The engineer had had the matter under his consideration, but he was hampered by the fact that they did not know whether the trams were to be worked electrically or not, and if so whether current would be supplied from the electric light station. If that matter were settled they could easily arrange for the supply of current to the principal streets of the town. In any case applicants for current were urgently applying from all parts of the town and something must be done to meet their wishes; therefore he thought it would be well to ask their engineer to consider and report upon what districts should be supplied, from what centres, and what system he thought most suitable to the present and future requirements of the town. It was decided to enter the Chairman's report in the minutes, and to consider the accounts at the next meeting.

ISLINGTON (LONDON).—On Friday last the electric light was experimentally turned on for the first time. The Vestry Hall and a number of shops on the opposite side of Upper-street were lighted. On Saturday considerable addition was made to the number of lamps lighted in business premises. Already the Lighting Committee has orders for the equivalent of 15,000 8 c.p. lamps, which is really a larger number than can be supplied from the existing plant. There is even now talk of extensions, and calculations roughly made indicate that even on the first year's working, unless some unforeseen difficulty should arise, an equilibrium between revenue and expenditure will be arrived at. It is stated that a considerable demand has arisen for factory lighting in the neighbourhood of the Regent's Canal, which passes through the Islington district.

JAPAN.—It is stated that a submarine cable is to be laid by the Japanese between Formosa, the newly acquired island, and Japan. The length is 594 nautical miles, and the contract price £65,980. The contract is stated to have been secured by a Japanese firm. Great progress is reported in electrical matters generally, the latest project being the construction of an electric tramway between the towns of Uraga and Tokosuka.

KIDDERMINSTER.—A meeting of the Town Council was held on Friday last for the purpose of considering the question of the proposed construction of an electric tramway from Kidderminster to Stourport. The General Purposes Committee presented a report on the scheme, and recommended the Council, subject to certain modifications in the plans which the promoters of the Bill had agreed to make, to approve of the Bill, and this recommendation was adopted.

LEEDS.—At the meeting of the City Council on Wednesday Mr. Hannam moved the adoption of the report of the Highways Committee on the question of equipping the local tramways electrically. An abstract of the Committee's recommendations was given in our last issue. After considerable discussion an amendment that "that portion of the minutes recommending the adoption of the conduit system of electrical traction in Boar-lane, be referred back," was carried by a large majority. The other portion of the report, which recommends the use of the overhead system over the remaining portion of the line, was adopted.

LLANDUDNO.—At a special meeting of the Urban District Council last week Mr. A. H. Preece was appointed consulting electrical engineer to the Council for the purpose of preparing a report on the electric lighting question.

MAIDSTONE.—The District Council have decided to adopt the recommendation of the Electric Lighting Committee to transfer their Provisional Order to a company which is being formed by Mr. Thomas King, electrical engineer, of Brighton and Maidstone.

MORLEY.—A letter from the Tradesmen's Association as to the adoption of an electric lighting scheme has been referred to the Electric Light Committee for consideration and report.

PETERBOROUGH.—At the last meeting of the Town Council the proposal to borrow £20,000 for electric lighting purposes was discussed. The engineer to the Council had estimated that this sum would be the probable cost of an installation for street and private lighting. The matter had been discussed in Committee, and the proposal had been made to dispose of the Corporation's powers under the Provisional Order to a company, but this had been defeated, and

Digitized by Google

the motion that the £20,000 be borrowed had been carried by nine votes to six. At the Council meeting Alderman Percival moved the non-confirmation of the Committee's minutes. Ultimately the Committee's decision was approved by eleven votes to six, and we are able to announce that Dr. J. A. Fleming has been appointed to advise the Council as their consulting electrical engineer.

PITLOCHRY.—At a meeting of the local gas company a scheme for introducing the electric light to this town was submitted by Prof. G. Forbes, whose estimate provides for a 200 H.P. turbine, and the necessary plant and apparatus to extend the mains as far as the Atholl Hydropathic, with branches to Oakfield, &c., at a total cost of £5,100, but as some portion of the scheme would remain in abeyance, Prof. Forbes considers that an expenditure of £4,000 is all that would be necessary for the present. This will provide current for an equivalent of 6,000 8 c.p. lamps. The up-keep is estimated at about £150 per annum. It was decided to delay decision until it was ascertained what number of lights would be taken up at once. The owner of the Hydropathic offers to take 800 lights forthwith.

PORTRUSH (IRELAND).—In addressing the shareholders of the Giant's Causeway Electric Tramway Company, at their annual meeting a few days back, the Chairman called attention to the item in the accounts having reference to the accident which occurred on the electric tramway, by which a cyclist met his death. The Directors, while denying any liability in the way of damages, decided to be liberal in the matter, which largely accounted for the somewhat considerable item of £159. 1s. under the heading "compensation." One result of the accident referred to has been that the Board of Trade have required the Company to adopt the overhead system instead of that of the present conductor rail. The change over to the overhead system is estimated to cost about £5,000, but the Company will by this outlay have considerably increased electric power available. The Chairman called attention to the anomalous state of affairs by which the obtaining of cheap money or absolute gifts from the English Exchequer was confined to those parts of Ireland which do nothing for themselves, while in the north of Ireland, where private enterprise has done and is doing so much, money can only be obtained at 4 per cent. The Company's line had not only opened up the old district from Portrush to the Giant's Causeway and developed the tourist traffic, but it afforded one of the best and cheapest outlets for the enjoyment and recreation of the working classes of Belfast and other commercial towns in the north of Ireland. During the year they had run their electrical cars at a cost of 4d. per mile, against 10½d. per mile, the cost of their steam cars, and the cheapness of electricity as a locomotive power was still fully maintained.

PORTSMOUTH TELEPHONES.—The Roads and Works Committee, on Monday last, had before them the consideration of the tenders sent in for laying the telephone wires in Portsmouth underground. The tender of Mr. Quick has been accepted by the Committee, but as the National Company are paying for the work the tenders have been sent to the Head Office, with a recommendation that Mr. Quick's offer be accepted.

PRESTON.—At the last meeting of the Town Council the Streets and Buildings Committee recommended that the contract made in June, 1892, with the National Electric Supply Company for the erection of 12 arc lamps in Fishergate, and the supply of current thereto, should be renewed, and that 30 additional 500 c.p. lamps should be erected in the principal streets of the town. The Company agreed to erect and supply current to these lamps at an inclusive charge of £14. 10s. per lamp per annum. The recommendation was adopted.

RIPON—The City Council have referred the question of formulating an electric lighting scheme for the City, to the Gas Committee. At the last meeting of the Council the Mayor said that the Dean and Chapter of the Cathedral, had agreed to postpond further consideration on the question of lighting the Cathedral electrically until their July meeting.

SLIGO.—The Town Council are making inquiries into the relative cost of electric and gas lighting, and a committee, consisting of the Mayor and Messrs. Foley and Gilcriest, has been appointed to collect information.

STAFFORD.—The County Council have decided to wire for the electric light the judge's lodgings at Stafford, providing the cost does not exceed £200.

SWANSEA.—The Town Council have received the report of Mr. W. H. Preece, who was recently appointed to give an opinion on the joint electric lighting, dust destructor and tramway scheme of the Corporation. It is stated that Mr. Preece's report is favourable to the carrying out of the scheme, and that practically all opposition to the Council's proposals will now cease.

WORCESTER.—At the last meeting of the City Council the Electricity Committee presented a report recommending the Council to apply to the Local Government Board for sanction to borrow a further sum of £5,000 for electric lighting purposes, the loan to be repayable in 30 years.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

January 18, 1896.

1,310. H. HIRST and A. E. ANGOLD. London. Improvements in electrical igniting apparatus.

January 20, 1896.

1,396. W. W. HULSE. London. Improvements in machinery or apparatus for transmitting motion from electric motors to other machinery.

1,401. A. A. NAVILLE, P. A. GUYE, and C. E. GUYE. London. Improvements in electrical gas-reaction apparatus.

January 21, 1896.

1,427. H. MARCUSE. Manchester. Improvements in and connected with telephonic apparatus.*

1,457. C. F. STEARN. London. Improvements in or connected with incandescence electric lamps. (C. F. Topham, Switzerland.)

1,487. P. CHAROLLOIS. London. An improved microphonic transmitter.

1,488. W. GRIMES. London. Improvements in or relating to electric batteries.

1,511. F. E. W. BOWEN. London. Improvements in the manufacture of filaments for electric incandescence lamps.

1,518. H. EDMUNDS. London. Improvements in means for the distribution of electricity simultaneously to circuits requiring current of uniform pressure and to circuits having variable load. (G. Mengarini, Italy.)

January 22, 1896.

1,559. J. H. DUNN and J. PARSONS. London. Improvements in making gases and steam by electricity.

1,563. R. PEARSON. London. Improvements in gravity electrical contact makers.

1,564. D. G. FITZGERALD and C. N. STEWART. London. An improved process for utilising peroxide of lead in the manufacture of elements for voltaic batteries.

1,565. T. HARPER. London. Improvements in electric switches.

1,574. SIEMENS BROS. AND CO. (LIMITED) and J. NEBEL. London. An improvement in electricity meters.

1,575. SIEMENS BROS. AND CO. (LIMITED). London. A process for the electrolytic production of zinc from its ores. (Siemens and Halske, Germany.)*

COMPANIES' MEETINGS AND REPORTS.

St. James' and Pall Mall Electric Light Company (Limited).

The ordinary general meeting of this Company was held on Tuesday at the offices of the Company, Carnaby-street Central Station, Golden-square, W., Mr. Eustace J. A. Balfour (Chairman) presiding.

The GENERAL MANAGER and SECRETARY (Mr. Frederic J. Walker) read the notice calling the meeting.

The CHAIRMAN: Before formally moving the adoption of the report and accounts, there are two or three observations I should like to make, chiefly in reference to the working of the Company since last the Directors had the pleasure of meeting the shareholders. I think we may fairly congratulate ourselves on the result of the year's working. We propose a dividend of 7¼ per cent. on the Ordinary shares, as against 6½ per cent. last year and 4½ per cent. the year before, and I am glad to say that the hope I expressed last year that there would be something to divide among the holders of the Founders' shares have been fulfilled. We propose on these shares a dividend of £?. 19s. 6d. each. During the year we have increased the number of lamps connected by 22 per cent., which is satisfactory, but what is still more satisfactory is the increase during the present year. Since January 1st we have had application for no fewer than 6,000 lamps, but in addition to that we have actually increased our gross revenue during the first four weeks of this year by £1,200. The actions for alleged annoyance from the plant at Mason's-yard station have been arranged. The Directors have arrived at the conclusion that it would be necessary to replace the whole of the engines there by new engines of the type similar to those in use at our Carnaby-street central station. This change was postponed as long as possible in order to ascertain the results of experiments carried on by ourselves and other companies, with the view of discovering the best method of overcoming the difficulty and trouble. Unfortunately no definite conclusion could be come to in time to stop the legal actions arising out of the annoyance. From the first, however, the Directors have been fully satisfied that the cure must be sought in the engine itself; in other words, it must not vibrate. Therefore, following up the experience gained at the Carnaby-street Central Station, we have proceeded to replace the plant at Mason's-yard. During the period under review rather more than one-half of it has been sold at a loss of £2,000, which has been charged to the revenue of that year, and, satisfied with the success of the new engines, the Directors have now decided to sell the remainder of the old engines and plant, and completely re-equip the station, and a further loss of about £1,500 must

Digitized by Google

be expected as a charge on the current year's working. At the same time steps have been taken at both stations to put a stop to all possible complaint from the emission of smoke and dust from the chimneys, and we feel confident that we can carry on the business of the Company without annoyance to our neighbours. In November a further issue of £20,000 of Debenture stock, making the whole issue up to £50,000, was made to the shareholders, and was considerably over-subscribed. Unless some unforeseen events should occur the Board do not anticipate that there will be any necessity for raising further capital during the present year. We expect shortly to receive an order from the parish of St. James to light the principal thoroughfares in this district, and this we are prepared to carry out. Last year we were able to announce that the cost of working had been reduced ¾d. a unit, and great credit is due to the staff for effecting a further reduction of ¼d. during the past year. Efforts have been made to come to an arrangement with the Founders shareholders, but unfortunately the offer of the Board, which, of course, was made subject to your approval, was not unanimously accepted, and it therefore fell to the ground. I regret to have to announce the resignation of my brother, Mr. Gerald Balfour, but on his appointment as Irish Secretary he did not consider himself justified in retaining his seat on the Board. Finally, I have again to thank Mr. Walker and Mr. Dobson and the whole staff for the zeal and ability they have shown this past year as in former years, and think we may, unless some unforeseen event occurs, look forward to the increased prosperity of the Company in the future. I now beg to move:—

That the report and accounts for the year ending December 31, 1895, as submitted by the Directors, be received and adopted, and that the dividends recommended therein be declared and paid on February 14th.

Mr. LATIMER CLARK, F.R.S. (Vice-chairman), seconded the motion.

Mr. FRANCIS BOURN expressed regret that the Directors had not been able to effect a settlement with the Founders' shareholders. Was he to understand that the holders of Founders' shares regarded their shares as priceless?

Mr. C. R. FRY said that as one who took a prominent part in the negotiations for bringing about an arrangement with the Founders' shareholders, he should like to be allowed to explain how matters stood. The proposal which emanated from the Board he considered a most fair and reasonable one, and he felt confident that the Ordinary shareholders would not have agreed to better terms being offered. Among the holders of the Founders' shares there were three or four gentlemen—all wealthy men—who evidently expected that some day their shares would be worth £500 or £600, and as it was impossible to get them to alter their views they refused to accept the offer made to them by the Directors. If the Founders' shareholders had agreed to dispose of their shares on the terms offered to them their position to-day would have been better than it was, and he believed the same might be said of their position during the next five years after making allowance for the progress of the Company during that period. As there were a few of the Founders' shareholders who refused the Board's proposal the negotiations fell through, as, unfortunately, the Articles of Association appeared to be drawn up in such a way as to make it possible for one objecting shareholder to defeat the whole thing.

Mr. FRANCIS BOURN asked if it would not be possible to alter the Articles of Association. Of course, they must not overlook the fact that the Founders' shareholders had their rights, but it was undoubtedly in the interest of the Company that the Founders' shares should be bought up. He would strongly urge, even if a large price had to be paid, that the Founders' shares should, if possible, be purchased.

Dr. WEBB observed that the Founders' shares had always been a millstone round their necks, and he should be glad to see them bought up, not at an exorbitant price, but at an extravagant price if necessary. The life of electric companies was only about 40 years, at the end of which time they might have to comply with various demands on the part of the public authorities before they obtained a renewal of their concession, or they might have to relinquish it on terms which would not restore to the shareholders their original outlay of capital. Therefore it would be a good thing if the Founders' shares could be bought up, in order to enable the Company to build up a reserve which at the end of 40 years would be sufficient to guarantee that they or their representatives would receive a return equivalent to the amount of money they had put into the Company.

The CHAIRMAN, in reply, said: I am entirely in sympathy with your desire to come to an arrangement with the founders. I think it is most important in the interests of the Company that we should do so, but of course it is a question of the balance of advantages. There is a point beyond which the Directors would not be justified in advising the shareholders to go in buying the Founders' shares. In our opinion the offer we made was the utmost limit we could reasonably advise you to agree to, and I concur with Mr. Fry in believing that the shareholders would not, as a body, have sanctioned any larger offer. That being so, we have come to the end of the matter. Of course our offer, or a similar offer, is still open to the Founders' shareholders. For myself I have longed to get this question settled, and as long as I am Chairman I shall use every endeavour to bring it to a successful termination. As to altering the Articles of Association, I may point out that to do that requires the same unanimity among the Founders' shareholders as the acceptance of our offer, so that we cannot get any further with that than with the other. It is unfortunate that such is the case.

Mr. FRANCIS BOURN: May I ask what the offer to the Founders' shareholders was?

The CHAIRMAN: This is the letter that was addressed to Mr. Fry, the Chairman of the Founders' Shareholders Committee:—

"July 3, 1895.

"Dear Sir: Your letter of June 20th was before the Directors at their meeting yesterday, and I am instructed to kindly ask you to inform the Committee of the Founders' Shareholders that the Board are prepared to advise the Ordinary shareholders to consent to the offer of an allotment of 80 ordinary shares at par for each Founders' share, but that they do not see their way to any increased offer. This, of course, is subject to the understanding that all the Founders' shareholders agree.

"F. J. WALKER,
"General Manager and Secretary."

The meaning of that is that at the then market value the founders would have got £280 per share, and at the present market value £400 per share.

Mr. FRANCIS BOURN said that, looking at the prospects of the Company, he considered that a very low offer.

The CHAIRMAN: I should point out that the market value of the Founders' shares was then £150, and we were offering £280.

Mr. FRY pointed out that if the offer had been accepted the founders would have received a consideration equal now to £360, whereas the market value of the Founders' shares to-day was £200.

The resolution was then carried unanimously.

The CHAIRMAN proposed the re-election of Mr. Bennett Fitch, M.Inst.C.E. and Mr. Walter Leaf as Directors.

Mr. FRY seconded, and the motion was agreed to.

On the motion of Mr. WAY, seconded by Mr. PIERCE, the auditors (Messrs. Deloitte, Dever, Griffiths and Co.) were re-appointed.

A vote of thanks having been accorded to the Chairman, the Board of Directors and the staff, the proceedings terminated.

Waterloo and City Railway Company.

The fourth half-yearly general meeting of this Company was held on Thursday at the Waterloo Station, London, Mr. Wyndham S. Portal (Chairman) presiding.

The SECRETARY (Mr. F. J. Macaulay) read the notice calling the meeting.

The CHAIRMAN: It may be of interest to you to know that the shareholders now number 553 against 541 at the last August meeting, and 494 at this time last year. I think I may say we meet the shareholders to-day under very favourable circumstances, as the engineers report that during the past six months there has been a continuous and substantial progress in every direction. The position of the undertaking is in every way satisfactory. At the close of the last half-year the tunnel was about 100 yards Citywards of the river Thames, but the engineers report they have now reached a point in Queen Victoria-street, nearly opposite St. Nicholas Church, a distance driven in the six months of 530 yards of double tunnel. These tunnels have been driven under the low level sewer, the Metropolitan Railway and Queen Victoria-street without mishap. They are in the solid London clay, and the rate of progress has been at the rate of 75ft. per week. These railway tunnels are now about 400 yards distant from the commencement of the City station, which will probably be reached in June next. Towards Waterloo the tunnels were, on July 22nd last, entering Stamford-street, but as they have had to encounter ballast and water, and have had to be worked under compressed air, the progress has been much slower. The average distance of the tunnels from the crossing of the Waterloo-road is about 120 yards, and the present rate of progress is about 23ft. a week. The length of the double tunnel driven in this direction since the last half-yearly report is 300 yards. The contract for the low-level station at Waterloo has been let at the engineers' estimates, and the works have been commenced by Messrs. Perry and Co., the contractors. The total length of single tunnel driven since the commencement of the works is 3,036 yards, being 69 per cent. of the entire length between the Waterloo station and the City station. With regard to the City terminus, which would be in the open space in front of the Royal Exchange, he might say that they had made arrangements with the Central London Railway Company, and were now in negotiation with the City authorities with every prospect of a successful result, and there was no reason to doubt that the undertaking would be completed within the time sanctioned by the Company's Act. On the 17th of last month His Majesty the King of the Belgians visited the works, and seemed to be extremely pleased with all that he saw. It might be hoped that when the undertaking was completed other royalties would do them the honour of visiting it, and, perhaps, of opening what was an exceptional and extraordinary work, combining both science and art. The accounts showed that the total amount of share capital received was £216,000, and the total expenditure £122,736. The sum expended in the past six moths was £62,321, and the estimated further expenditure of capital to June 30th next was £105,000, to meet which they would, in all probability, have to make another call. There was nothing more for him to say except to congratulate the engineers, Mr. Galbraith and Mr. Greathead on the progress they had made so far, and on their wonderful immunity from accidents of all sorts, and to assure them of the earnest hope of the Board that things would go on to the end with the same satisfaction to themselves and to the Directors as they had done from the beginning to the present time. He then moved—

"*That the report of the Directors and statement of accounts for the half-year ended December 31, 1895, be, and the same are hereby received and adopted.*"

Lieut.-Col. Hon. H. W. CAMPBELL (Deputy-Chairman) seconded the resolution.

Mr. BEAVIS asked if, in making the next call, the Board would give to those shareholders who wished to do, the option of paying up the full amount uncalled on the shares.

The CHAIRMAN: We can only give that option on the same conditions as I mentioned at a previous meeting. If you like to pay up in full you may, but it must be without interest being paid.

Mr. L. H. RUEGG said the report was an admirable one, and they would find some difficulty in saying too much in favour of the Board. They

Digitized by Google

were very happy in having on the Directorate so many members of the South-Western Company. He ventured to predict, in regard to this line, that it would ultimately be a more valuable property than the South-Western Railway.

The CHAIRMAN, replying to a shareholder, who asked if the works might be inspected, said the engineers would readily accede to the desire of any shareholder to visit the undertaking during construction, but only a few could be accommodated at the same time.

A SHAREHOLDER: No liability will attach to the Company for accidents, I suppose?

Sir CHARLES SCOTTER: No, each shareholder's visit must be at his own risk.

The resolution was then carried unanimously.

The retiring Directors, Mr. W. S. Portal, the Right Hon. Sir Algernon West, K.C.B., and Mr. P. Mortimer, were re-elected.

A special general meeting followed, at which, on the motion of the CHAIRMAN, seconded by Lieut.-Col. Hon. H. W. CAMPBELL, the following resolution was carried:—

"That this meeting having considered the Bill now pending in Parliament intituled 'A Bill to confer further powers on the Baker-street and Waterloo Railway Company,' approves thereof with such modifications, if any, as may be agreed to by the Directors and sanctioned by Parliament."

Yorkshire House-to-House Electricity Company (Limited).

A meeting of this Company was held on Tuesday. Mr. Grosvenor Talbot, the Chairman, presiding.

The CHAIRMAN said that out of capital they had expended £12,468 during the year, bringing up their total capital expenditure to £76,526. They had made very considerable extensions in mains, and of those they had expended £6,080, on machinery £3,380, £2,240 on new transformers and meters, and the balance had been spent on buildings. The profit available for dividend amounted to £6,483. In July they declared an interim dividend at the rate of 4 per cent. per annum, which took exactly £1,000. The Directors now recommended a dividend at the rate of 6 per cent. per annum for the half-year just ended, making 5 per cent. for the whole year. That required £1,675. 7s. 7d. The Directors proposed to carry to reserve, depreciation, and other purposes, £3,300, leaving £517. 16s. 4d. to carry forward. In addition to the dividend, during the year, by a recent issue of shares, shareholders had as many new shares offered to them at par as the number which they then held, and as the £5 shares were now selling at £7 to £7. 7s. and those on which £1 had been paid were selling at £2. 7s. 6d., the Directors felt that that was equivalent to a very handsome bonus. They also felt that it was very desirable that they should accumulate a considerable reserve fund. Up to the present time they had no reason to regret a single step that they had taken in the erection of the plant and machinery, but there were possibilities in electrical science which they must always bear in mind, and which possibly might render advisable expensive alterations that they would more willingly entertain if they had in hand a considerable reserve. Last year the business had been satisfactory. The total receipts had been £11,431, compared with £7,457 in the previous year; and their expenses had been £4,617, against £3,747 in 1894. The net profit was £6,780, compared with £3,700 in 1894. Thus the total revenue had increased by 57 per cent., and the expenses had only increased by 25 per cent., while the available profit was 82 per cent. more. In 1891 they had an installation of 19,858 8-candle power lamps; in 1895 they had 32,539 lamps. In 1894 their total output was 291,113 units, and in 1895 it was 525,629 units, showing the great desire there was to use the electric light in the city of Leeds. The cost of coal had been only £670 for the year, which beat the record per unit of any station in the United Kingdom. The electric light had, he thought, been amply proved to be the safest now in use, and its great safeguard against fire should enable their customers to obtain more advantageous rates with the insurance companies. As to new plant, the Directors had ordered two vertical engines of 500-H.P. each, running at 355 revolutions, with direct coupled alternators. This involved to a certain extent a new departure, as there was no station in England where a plant was in existence similar in every way to what they required in Leeds, and running under such stringent conditions. The new engines and alternators would run in parallel with the old plant, also with themselves alone when needed, and the whole plant would be practically noiseless. He had to convey to their engineer, secretary and staff the appreciation of the directors for the manner in which the Company's work had been performed during the year.

Cuba Submarine Telegraph Company, Limited.

The report of the Directors of this Company for the half-year ended December 31 last, to be presented at the forty-ninth ordinary general meeting of Shareholders, held at the offices, 58, Old Broad-street, London, E.C., on Wednesday next, at 12 o'clock, states that the gross receipts amount to £25,663. 16s. 11d., and the gross expenditure to £6,034. 14s. 4d., leaving a sum of £19,579. 2s. 7d., which, added to the balance of £3,539. 19s. 9d., brought forward, leaves £23,119. 2s. 5d. at the credit of revenue account. The sum of £10,000 has been added to the reserve fund, which now stands at £120,000. The dividend on the Preference shares will absorb £3,000, and leave £10.119. 2s. 5d., out of which the Directors recommended the payment of a dividend on the Ordinary shares at the rate of 8 per cent. per annum, free of income tax, the balance, £3,719. 2s. 5d., being carried forward. The Company's cables have continued in good order throughout the half-year, but during the present month the Cienfuegos-Santiago 1875 cable has broken down and been repaired by Mr. Keith.

In consequence of the insurrection in Cuba, which still continues, the Spanish Government suggested to the Company to connect the town of Manzanillo with one of the two existing cables running from Cienfuegos to Santiago; but as these cables were laid in 1875 and 1881 respectively, the Board considered it undesirable to disturb them. Further proposals then followed from the Government, resulting in the Company obtaining a concession to lay a cable between Cienfuegos, Casilda, Tunas, Jucaro, Santa Cruz, and Manzanillo, with a subsidy of £2,000 per annum, from 1st January, 1896, till 27th August, 1910, which is the date when the original concession expires. This cable has been successfully laid by the contractors and duly taken over by Mr. Keith on behalf of the Company. It is about 300 nautical miles in length, and the Directors trust it will not only prove useful to the Government, but to the general public. As the new line extends the greater part of the route traversed by the cables of the Cienfuegos-Santiago section, it will require only the laying of the short length between Manzanillo and Santiago to give a new line of communication between the first-mentioned points, but it is not proposed to do this until the failure of either of the old cables should render such a step advisable. The cost of the new cable, approximately about £45,000, will be charged to the reserve fund in the current half-year's account.

The position of the Company's suit against the Spanish Government at Madrid remains the same as at the date of the last report.

Westminster Electric Supply Corporation (Limited).

The following report is issued by the Directors of this Company and will be presented to the shareholders at the meeting to be held at the offices, Eccleston-place, S.W., on Wednesday, the 19th inst., at 11 o'clock:—

The business of the Corporation continues to make satisfactory progress. The supply of current, which on December 31, 1894, was provided for the equivalent of 167,705 lamps of 8 c.p., had increased by December 31, 1895, to the equivalent of 210,982, and at the present time there are on circuit the equivalent of 216,822 lamps of 8 c.p., and applications have been received for a further 6,478. The length of roadway in which mains have been laid now exceeds 39 miles, making about 156 miles of ways, into which upwards of 123 miles of copper (strip and cable) have been drawn. The plant and machinery have been working satisfactorily throughout the year, and have been fully maintained from revenue, and a further reduction has been effected in the cost per unit, in generating, distributing, and general expenses. In consequence of the increase in the business of the Corporation the Directors have found it necessary to acquire additional property at Eccleston-place and Millbank-street. In dealing with the revenue of the past year the Directors have, after writing off bad debts, a portion of preliminary expenses, and placing £953 to credit of sinking fund, added a sum of £9,780 to the depreciation account. The net revenue of the year amounts to £23,731. 11s. 9d., out of which an interim dividend, at the rate of 5 per cent. per annum, for the half-year ended June 30th last, has been distributed. The Board now recommend the payment of a dividend at the rate of 9 per cent. per annum, less income tax, for the past half-year, making 7 per cent. for the year ending December 31st last, carrying forward £1,333. 14s. 10d. The holders of Founders' shares becoming entitled to a share of the surplus profits after payment of a dividend of 7 per cent., this balance will be carried forward as follows:—

Ordinary Shareholders' undivided profit account ...	£1,004	1 2
Holders of Founders' shares " "	334	13 8

The Premium of £3,000 received on the issue of new shares has been carried to the credit of the reserve fund, and invested.

Messrs. J. H. Powell and J. Browne Martin offer themselves for re-election as Directors.

Liverpool Overhead Railway Company.

The following report of the Directors of this Company for the half-year ended December 31st last is issued, and will be submitted to the fifteenth half yearly general meeting of shareholders to be held at the Law Association Rooms, Cook-street, Liverpool, on the 11th inst. at three o'clock.

The gross revenue receipts amount to £31,590. 6s. 11d., and the working expenses to £18,893. 19s. 3d. The number of passengers carried each half-year since the opening of the railway is as follows:—

	June 30, 1894.	Dec. 31, 1894.	June 30, 1895.	Dec. 31, 1895.
First Class	277,653...	362,179...	400,260...	444,762
Second Class	1,246,975...	2,228,224...	2,114,462...	2,374,794
Workmen (Special Return Tickets)	1,336,809..	1,050,976...	945,338..	960,819
	2,861,437...	3,641,379..	3,460,060...	3,780,375

The works in connection with the Southern Extension are making good progress, and it is anticipated that the additional line will be open for traffic in the autumn of 1896.

The revenue account shows receipts from passenger traffic £31,080. 16s. 3d., and miscellaneous receipts £509. 10s. 8d.; total £31,590. 6s. 11d. Working expenses £18,893. 19s. 3d. and interest on Debentures £2,500. This leaves, with balance brought forward (£1,302. 18s. 11d.), £11,499. 6s. 7d. available for dividend. Out of this balance the Directors recommend dividends at the rate of 5 per cent. per annum on Preference shares, absorbing £2,600, and 3½ per cent. on Ordinary shares, taking £6,825, leaving £2,074. 6s. 7d. to be carried forward.

Sir W. B. Forwood (Chairman) and Mr. H. Brocklebank offer themselves for re-election as Directors, and Mr. George Nicholson as auditor.

NEW COMPANIES, STATUTORY RETURNS, &c.

SIR W. G. ARMSTRONG AND CO. (LIMITED).—This Company was registered on January 31st, with a nominal capital of £4,000,000, in 200,000 £4 per Cent. Cumulative Preference £5 shares and 3,000,000 Ordinary £1 shares, to acquire the business and undertaking of Sir W. G. Armstrong, Mitchell and Co, Limited (incorporated in 1882), to enter into an agreement with the old Company for that purpose, and to carry on the business of hydraulic, electrical and general engineers, ordnance and gun makers, torpedo manufacturers, shipbuilders, machine and engineering tool makers, &c. The first Directors are:—Lord Armstrong, Sir A. Noble, K.C.B., Adm. Count Albini, W. D. Cruddas, M.P., Col. Henry C. S. Dyer, Hon. Edward F. L. Gower, Saxton W. A. Noble, George Rendel, H. O. Rendel, Lord Rendel, H. F. Swan, J. Vavasseur, P. Watts, P. G. B. Westmacott and Lt.-Gen. C. W. Younghusband.

COX THERMO-ELECTRIC COMPANY (LIMITED).—This Company was registered on February 3rd, with a capital of £100,000 in £10 shares, to apply for, purchase, or acquire any patents, patent rights, licences, concessions, and in particular inventions relating to the direct generation of electricity from heat by means of thermopiles or thermo-electric generators, and to the construction, maintenance, improvement or working of thermopiles or thermo-electric generators of any kind; to enter into an agreement with Mr. H. B. Cox, engineer, and Messrs. R. W. Wallace and F. J. Webster, and to carry on the business of manufacturers of and dealers in thermopiles and thermo-electric generators, mechanical engineers, machinists, dynamo makers, manufacturers of cars, vans, carriages and vehicles of all kinds, suppliers of electricity, manufacturers of and dealers in electrical apparatus, metal founders, &c. The subscribers, with one share each, are: H. B. Cox (engineer), Mrs. Clara L. Cox, W. Churcher, J. Macfarlan, T. Dunsdon, E. Dry and H. Elliott. Mr. H. B. Cox is to be a life Director of the Company.

ERNEST SCOTT AND MOUNTAIN (LIMITED).—The annual return has just been filed. Out of a capital of £70,000 in £10 shares, 5,763 have been taken up, and 2,200 have been issued as fully paid. The full amount has been called on 1,082, £6 5s. per share on 1,981, and £5 per share on 500

EPSTEIN ELECTRIC ACCUMULATOR COMPANY (LIMITED).—The annual return to December 31st has just been filed. The capital is £101,000 in 1,000 Founders' and 100,000 Ordinary shares of £1 each. All the former and 70,307 of the latter have been taken up, and 1,000 Founders and 70,007 Ordinary shares have been issued as fully paid. The full amount has been paid on the remaining Ordinary shares.

EUROPE AND AZORES TELEGRAPH COMPANY (LIMITED)—The annual return to December 31st has been filed. The capital is £200,000, in £10 shares, and 16,704 of these have been taken up. 5,568 have been issued as fully paid, and the full amount has been paid on the remaining 11,360 shares.

FOREIGN AND COLONIAL ARC ACCUMULATOR COMPANY (LIMITED).—The annual return, to December 6th, has been filed. The whole capital of £1,000, in £1 shares, has been taken up, and 993 have been issued as fully paid.

TELEGRAPH IMPROVEMENT COMPANY (LIMITED).—The annual return, to December 27th, has been filed. Out of a nominal capital of £100,000, in £1 shares, 15,006 have been taken up, 15,000 have been issued as fully paid, and the full amount has been paid on the remainder.

CITY NOTES.

MEMORANDA—Bank rate, 2 per cent. (Feb. 22, 1894). Price of silver, 30⅞d. per oz. (Feb. 6th). Consols (2¾ per cent.) 108 1/16 – 108 1/16 for money, 108 1/16—108 5/16 for account; 2½ per cent. 104⅞—105⅛ (Feb. 6th). Stock Exchange Settling Days: Consols, March 2nd; Stocks and Shares Continuation Day, Feb. 11th; Ticket Day, Feb. 12th; Pay Day, Feb. 13th; Mining Share Carry-over Day, Feb. 10th.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended February 2nd were £991, against £1,021 in the corresponding week of 1895, a decrease of £30. The total receipts for the half-year amount to £5,026, against £5,020 for the corresponding period of 1895, an increase of £6.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the month of January were £2,578, against £1,878 in the corresponding period of last year.

EASTERN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of January amounted to £78,886, against £70,674 in the corresponding period last year.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of January amounted to £49,693, and to £41,315 in the corresponding period 1895.

EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY (LIMITED).—The Directors of this Company resolved on a payment on account of the dividend of the current year, at the rate of 5 per cent. per annum, less income tax, on the A shares of the Company, in respect of the half-year ended December 31st last. This works out as follows: On 89,261 £5 shares (£3 paid), 1s. 6d. per share; on 17,139 £5 shares (fully paid), 2s. 6d. per share. Dividend warrants will be issued on the 18th instant.

GIANT'S CAUSEWAY AND PORTRUSH ELECTRIC TRAMWAY COMPANY (LIMITED).—The annual meeting of the shareholders of this Company was held on the 31st ult., when the Directors' report and accounts for the past year were approved. The report stated that during the year there had been an increase in the number of passengers carried of 5,700, the total for the year being 99,616. The receipts from this department rose from £2,873. 13s. 11d. to £3,107. 9s. 5d., while the receipts from the carriage of mineral rose from £12. 5s. 1d. to £14. 8s. 7d. The total receipts were £3,156. 1s. 6d., against £2,914. 6s. 5d., and the expenditure amounted to £2,426. 5s. 2d. against £2,189. 8s. 3d. in 1894. The increased expenditure was principally caused by a right-of-way lawsuit in which the Company became involved.

GREAT NORTHERN TELEGRAPH COMPANY (LIMITED).—Notice is given of the drawing of 100 1883 Debentures (Series B) of £100 each, for payment on March 1st next. The Debentures will be paid by Messrs. C. J. Hambro and Son, 70, Old Broad-street, London, E.C. This Company's traffic receipts in January were £22.490, against £21,000 and £23,200 in the corresponding month of 1894 and 1895 respectively.

GREAT NORTHERN TELEGRAPH COMPANY.—The receipts of this Company for the month of January amounted to £22,400, as against £23,200 for the corresponding month of 1895, and £21,000 for that of 1894.

JOHN FOWLER AND CO., LEEDS (LIMITED).—During the week the Law Debenture Corporation invited, on behalf of this Company, applications for £200,000 Four per Cent. First Mortgage Debentures of £100 each, repayable on January 1, 1926, at £105, and redeemable, at the Company's option, on six months' notice at any time on or after Jaunary 1, 1911, at £110 per cent. Holders of current Four and a-Half per Cent. Debentures to the amount of £96,500 have applied for Debentures of the present issue in exchange for the old Debentures. The issue price was at the rate of £105, payable £10 on application, £45 on allotment (£5 premium), and £50 on March 9th. The prospectus states that the Company has recently given increased attention to the manufacture of plant for the generation of electric light and power, and the paid-up capital amounts to £374,430 (£284,430 in £10 fully-paid £5 per Cent. Preference shares, and 18,000 Ordinary £10 shares, £5 paid).

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended the 2nd inst. amounted to £1,044. The amount for the corresponding week last year was £924. Increase, £120.

MANITOBA ELECTRIC AND GAS LIGHT COMPANY.—A notice is issued by holders of one-fifth in value of the Debentures of this Company announcing that the trustees, under the trust deed of December 8, 1886, having made default in calling a meeting of the debenture holders, it has been decided that a meeting shall be held at the offices of Messrs. R. A. McLean, of 1, Queen Victoria-street, London, E.C., on Friday, the 18th inst., at 12 o'clock, for the purpose of passing resolutions to remove one of the trustees under the said trust deed, and to prescribe regulations for the future calling of meetings of the debenture holders. A large number of the Company's Debentures are held in this country.

NATIONAL TELEPHONE COMPANY (LIMITED).—The Directors of this Company recommend the payment of dividends for the half-year ended December 31st at the rate of 6 per cent. per annum (less income tax) on the amounts paid up on the First and Second Preference shares, at the rate of 5 per cent. per annum (less income tax) on the amounts paid up on the Third Preference shares, and at the rate of 6 per cent. per annum (free of income-tax) on the amounts paid up on the Ordinary Shares. £35,000 has been placed to reserve, and about £5,000 carried forward. The transfer books of the Preference and Ordinary shares of this Company are closed from the 7th to 20th inst., inclusive, preparatory to the payment of dividend for the half-year to December 31st.

TOWN AND VILLAGE ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—This week a prospectus has been issued inviting subscriptions for 15,440 Ordinary shares of £5 each, payable £1 on application, £2 on allotment, and the balance in calls not exceeding £1 as may be required. The capital of the Company is £100,000 in 19,800 £5 Ordinary shares, and 1,000 £1 Founders' shares. 4,360 shares are to be allotted to the vendors in part payment of the purchase money, and the Founders' shares will not rank for dividend until 10 per cent. per annum has been paid on the Ordinary shares, after which they will be entitled to one-half of the profits. The Company has been formed for the purpose of acquiring certain letters patent for the United Kingdom, Germany, Austria, Canada, and the United States, from Messrs. G. J. and G. J. T. J. Parfitt, for an improved method of electric lighting in series and apparatus therefor, together with the freehold lands, plant, stock-in-trade and existing contracts of the Western Counties Electric Light and Power Syndicate, Limited. Our readers will find this system of electric lighting was described in our issue of May 10, 1895. The Directors of the new Company are: Messrs. T. H. Harrison, M.I.M.E., A.I.E.E. (London manager of Messrs. Davey, Paxman and Co.), E. B. A. James, John Lowles, M.P., W. Pierce and A. Thompson. Mr. G. J. T. J. Parfitt is electrical engineer-in-chief; the secretary is Mr. H. A. Tobias, and the offices are at 11, Queen Victoria-street, E.C. The list opened on Wednesday, and closed yesterday (Thursday) for town, and closes at noon to-day for the country.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—This Company's traffic receipts for the week ended January 31st, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,990.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the half month ended January 31st are £3,007, against £2,747 in the corresponding period of 1895.

WESTERN UNION TELEGRAPH COMPANY.—Numbers are published of 13 bonds, six of £100 each and seven of £200 each, which were drawn on the 15th ult., for redemption on March 2nd next of the Company's Six per Cent. Sterling Loan. Messrs. Morton, Rose and Co. are agents for the loan.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861—1878.

No. 926. [Vol. No. 16. XXXVI.] FRIDAY, FEBRUARY 14, 1896. PRICE SIXPENCE.

NOTES.

ALTHOUGH, in view of the recent Conference at Westminster, the Board of Trade, when sending out copies of the new Electric Light Regulations to the various parties concerned, has not deemed it necessary to *invite* comments and amendments, the Regulations, until they are issued officially as Board of Trade bye-laws, so to speak, are not beyond reach of further revision if such can by any possibility be necessary after the ample discussion to which they have been subjected. Only two points appear to call for notice. When Regulation 23, relating to the mode of suspension of high-pressure overhead lines came up for discussion at the Conference, Mr. CROMPTON argued vigorously that hard-drawn copper wires were less likely to tumble down when suspended direct than when suspended from corrodible steel wires by means of leather thongs. This point, it was promised, should be carefully considered—it has not been conceded. When the Conference rose, it was understood that the point at which electric light undertakers were to cut off a consumer's supply or to refuse to connect up, was to be determined by a k/n law, n being the number of points for taking off current, k being a constant member of megohms, 75 being the favourite figure with the meeting. In the regulations as they now stand the cut-off point is defined as having been reached when the leakage current from wires and fittings exceeds "one ten-thousandth part of the maximum supply current to the premises." A somewhat different principle and a much lower standard.

AMID the hurly-burly caused by the almost daily discovery of X-rays, Y-rays, or Z-rays, with conflicting properties and puzzling characteristics, we are in some danger of forgetting our indebtedness to the original discoverers of the scientific field, the cultivation of which is to-day yielding results that have set the world of science agog with half-baked hypotheses, and have caused even the most sober-minded to become hopeful of the immediate solution of some of the fundamental enigmas of physics.

To the public science is "as tedious as a twice-told tale, vexing the dull ear of a drowsy man," unless it makes a discovery of obvious practical utility or one which is reducible to something concrete, like a shadow-picture of the human interior. Intensely interesting as the structure and deformities and diseases of the human hand must be to all of us, the thought that we may be on the brink of an experimental verification of the existence of longitudinal etherial vibrations within sight of a solution to the gravitation mystery, or about to extort from Nature the well-kept secret of the true nature of Electricity, renders the physicist temporarily oblivious to the exact condition and configuration of his phalanges or metacarpal bones. In view, therefore, of the grand scientific possibilities of X-rays and cathode-rays and the like, do not let us forget CROMWELL VARLEY, the prime discoverer in this great affair. Electrical engineers also should be especially mindful of the labours of CROOKES, who, as their President in 1891, treated his audience to probably the most fascinating Presidential Address of the five and twenty delivered since the foundation of the Institution of Electrical Engineers. Members who had the good fortune to hear that glowing discourse on "Electricity in Transitu: from Plenum to Vacuum," to see the molecule-mill revolve and to follow the speaker's triumphant disproof of HITTORF's and PULUJ's objections, are in no danger of imagining that the cathode ray species was born fully fledged in Continental laboratories. Those desirous of apportioning the credit where it is due will do well to read the extract from Lord KELVIN's 1893 Anniversary Address to the Royal Society, which we publish in another column. In this will be found not only references direct or indirect very nearly completing the history of all that has been done since the time of FARADAY in the investigation of the transmission of electricity through highly rarefied gases; but also a vaticination of the then President of the Royal Society, which, in the light of the RÖNTGEN rays, is most instructive reading: "If a first step towards understanding the relations between ether and ponderable matter is to be made, it seems to me that the most hopeful foundation for it is knowledge derived from experiments on electricity in high vacua. . . . ."

ON Wednesday morning we received a telegram from Prof. BORGMAN, of St. Petersburg University, which, on being interpreted, reads as follows:—

RÖNTGEN rays discharge rapidly positive electricity, slower negative. *At short distances they give negative electrification.* They increase spark-gap. Aluminium sheet does not hinder either action.

THE phenomenon of the discharge of negatively *and positively* electrified bodies by RÖNTGEN rays was pointed out in our columns last week by Prof. J. J. THOMSON and Prof.

Digitized by Google

Oliver Lodge, and this week we publish a brief abstract of some experiments in the same direction by MM. Benoist and Hurmuzescu. The interest of Prof. Borgman's telegram lies, therefore, in his discovery that Röntgen rays, like cathode rays, negatively electrify bodies, that, like Hertzian waves, they increase the sparking distance for a given potential difference, and that they discharge positively electrified bodies more quickly than they do negatively-electrified ones; a statement, by the way, the direct contrary of that of MM. Benoist and Hurmuzescu.

The extent of the elevator industry in America, and, in consequence, its importance in providing a day load for hydraulic and electric supply stations, may be gathered from the fact that in New York there are no less than 5,000 elevators, and, as Mr. F. J. Sprague graphically puts it, "more people are carried vertically than there are horizontally." We are not quite so fond of the "lift" in this country as they seem to be in America. Nevertheless, in our largest cities there is quite a respectable amount of passenger and goods elevator work going on, which, if it could be wholly annexed by the electric supply concerns, would go a long way to fill up the annoying and expensive valleys in the load diagrams In London the hydraulic power stations had last year an aggregate capacity of 3,400 h.p., and at Manchester, Liverpool and Glasgow the amount of power was in each case 800 h.p. A Paper recently read by Mr. F. J. Sprague before the American Institute of Electrical Engineers, on "Electric Elevators," an abstract of which we publish this week, attempts to show that by comparison with the hydraulic elevator the electric elevator is superior. While not forgetting that comparisons which hold for the United States are not necessarily true for this country, it is to be regretted that Mr. Sprague has omitted to give any figures showing the actual relative costs of hydraulic and electric elevation. From the large amount of electric elevator work done in the States we gather that the comparison would be more favourable there than here. So far as London prices are concerned, Mr. E. B. Ellington (see *The Electrician*, Vol. XXXV., p. 485) has shown that in regard to works costs hydraulic power can be generated (by steam) at 25 per cent. less cost than electric power (also by steam). Comparison between the distribution expenses are difficult to make; but it has been shown that with hydraulic power supplied at 1s. 6d. per 1,000 gals.—the London price—a useful horse-power at the motor pulley will cost 3d. per hour. Possibly those electric supply concerns which charge only 3d. per unit for power in the daytime might rival this, if the motor were efficient and well loaded. But it will be evident that unless electric power is quite as cheap as this the superior efficiency of the electric motor, upon which M. Sprague lays so much stress, will not in this country suffice to beat the hydraulic elevator out of the field.

Recent research has thrown a good deal of light on the electrical origin of comet tails. These appendages of nebulous hydrocarbon are not a permanent possession of a comet, but, as has long been observed, are developed only when the comet is near perihelion. As the comet recedes from the sun the tail gradually condenses. Moreover, the axis of the tail is always extended radially away from the sun, giving evidence of what has been thought to be electrical repulsion. In a recent number of the *Astrophysical Journal* Prof. Fessenden suggests that the ultra-violet rays falling upon that side of the nucleus which is turned towards the sun cause negatively-charged particles to be emitted, the nucleus remaining positively charged. Researches by Prof. J. J. Thomson indicate that the solar chromosphere is negatively electrified; and the spectra of cometary tails, resembling as they do the candle spectrum, support the hypothesis of negatively electrified tails. There will, then, be four forces acting on the particles projected from the inner surface of the nucleus—namely, the solar electrical repulsion, the mutual electrical repulsion, the electrical attraction of the nucleus and gravitation. These forces will determine the form of the tail; and it would seem that all the special differences in comet structure are capable of explanation on this hypothesis. A solar potential of about 15,000 volts is apparently required.

Electric Mountain Railway in Austria.—The Austrian Government authorities have given permission for the preliminary work in connection with the proposed electric railway up the Schneekoppe, a mountain 5,320ft. high.

Oil Fuel in the Navy.—It is an interesting testimonial to the quick steam-raising and forcing powers of oil firing for boilers that the Admiralty have authorised its adoption in the "Gladiator," a cruiser which is now being built at Portsmouth.

Lord Kelvin's Jubilee.—Lord Kelvin reaches this year his jubilee as Professor of Natural Philosophy in the University of Glasgow. The event, says *Nature*, will be recognised by a joint celebration, in which the City, University, and students will take part, on June 15th and 16th.

Cable Interruptions and Repairs:—

	Date of Interruption.
Puerto Plata—Martinique	December 19, 1895
Perim—Obock	January 2, 1896
Odessa—Constantinople	January 17, 1896

Obituary.—The tragic death of Lieut. Swift, of the United States, is announced. He was considered one of the most expert telegraphers in the United States Army. One of his favourite achievements was to send a message with one hand while he wrote down a received message with the other. Another trick he would perform was to take a message from an instrument with one hand, while he copied another message with the other hand.

Amazon Telegraph Company.—This Company inform us that cable communication between Pará and Manaos, the capital of the province of Amazonas, has been successfully completed. Messages of congratulation have been exchanged between the Directorate in London and the Brazilian Government. The line is now open for messages between these two places, thus bringing Manaos in direct telegraph communication with Europe and the rest of the world.

Finsbury Technical College Conversazione.—The students of the Finsbury Technical College are holding their biennial conversazione on Thursday, February 20th, for which Prof. Silvanus Thompson has been induced to prepare a lecture on "Invisible Light and its Photography." The lighter portion of the programme consists of a concert and dance, while the whole of the College not used in the entertainment is to be given up to exhibits of model machinery, electrical appliances and chemical manufactures.

Niobium Filament Lamps.—Experiments are being carried on by Mr. J. W. Aylsworth, of Newark, N.J., on the manufacture of incandescent lamp filaments of niobium and other refractory rare metals. The method which he adopts consists in deposit-

Digitized by Google

ing the metal on a carbon filament, the process being continued until a filament of the required thickness is produced. The deposition of the metal is brought about by incandescing the carbon filament in a bulb containing halogen compounds of the metal, a current of hydrogen being passed through at the same time, the salts being heated by a Bunsen burner.

Gas Engine Station for Block Lighting.—The following, says the *Gas World*, are the data of an electric station at Frankfort-on-the-Main, where a block of buildings is supplied with current from a 70-H.P. gas engine, without any of the costs of distribution to a distance. The lamps are about one to every 2½ square yards of ground area. Storage batteries are used. The number of lamps correspond to 2,200 16-c.p. lamps, of which 1,800 are at work simultaneously during business hours. The consumption is 490,000 ampere hours, corresponding to 445 hours per lamp. The costs are:—Gas, £424.; oil, &c., £52; water, £41.; storage battery insurance, £100; distilled water and sulphuric acid, £16; rent and charges, £80; wages, £160; repairs, &c., £22.; total, £895; or per 16-candle lamp per hour, 0.200d. The undertaking has paid 7½ per cent. after writing off depreciation, &c.

Errata.—In our editorial Note on p. 469, last week, on the Röntgen rays, the phrase "the photographic plate, in addition to being merely qualitative or at any rate directly quantitative," should have terminated instead with "at any rate *not* directly quantitative."——In the Note at the bottom of the first column on the same page, Prof. Michelson is made by the printer to end his "declamation" in an incoherent fashion, whereas what he really said was: "This their problem: to penetrate, as far as it is permitted to human reason, that mysterious whole we call matter, whose solar systems are molecules, whose worlds are atoms."——In Dr. Lodge's article in our last issue, on p. 472, line 5 from top, there also occurs an obvious misprint. The last sentence of the paragraph should read "Bells and plates of atomic size would vibrate at about the required pace —viz., 400 to 800 million *million* vibrations per second."

Royal Society.—The following Papers were down for reading yesterday:—Dr. J. N. Collie and Prof. Ramsay, F.R.S., "On the Behaviour of Argon and Helium when submitted to the Electric Discharge;" Lord Kelvin, F.R.S., "On the Generation of Longitudinal Waves in Ether;" Prof. J. J. Thomson, F.R.S., "On the Discharge of Electricity produced by the Röntgen Rays, and the Effects produced by these Rays on Dielectrics through which they pass."——The date fixed for the next "meeting for discussion" at the Royal Society is April 23rd, when the subject will be "Colour Photography," and the discussion will be opened by Prof. Lippmann.——The Bakerian Lecture will be delivered before the Royal Society on the 20th inst., the lecturer for the year being Prof. Roberts-Austen, and the subject, "The Diffusion of Metals." The Croonian Lecture will be given probably on March 12th, by Dr. A. D. Waller, who has chosen for his subject, "Electrical Changes in Isolated Nerve."

Gas Engine Central Station in Chicago.—The gas engine electric supply station in Chicago, of which we have previously given some particulars, is now in operation. The engines are double-acting and of English manufacture, their rated power being 80, 130 and 200 H.P. respectively. The largest engine is of the tandem 2-cylinder type, and all three are belted to the dynamos. The station is used for lighting six of the city blocks, and has a capacity of 4,000 lamps of 16 c.p. An interesting feature in this station is the use of natural gas for driving the engines, the gas being pipe-lined from Indiana gas fields, some 175 miles from Chicago. We may state that American natural gas has a very high thermal value, the gas having twice or more heating power than good coal of equal weight. About 30,000 cubic feet of the gas equals one ton of good coal. As compared with producer gas, natural gas is much cleaner in burning in a gas engine. This station should therefore develop some interesting and economical results.

Expiring Patents.—On Saturday next, the 15th inst., will expire patent No. 370, granted to C. A. Faure for "Improvements in Apparatus for Measuring and Registering Electric Currents." The claims are for—(1) Apparatus for measuring and registering an electric current, in which a conductor carrying the current rotates about a magnet, and controls another circuit in which is included an electromagnet, or like instrument, propelling a mechanical counter; and (2) apparatus for measuring electric currents, in which the current to be measured is caused to pass through the coils of an electromagnet, and through a conductor, which then revolves under the influence of the current and of the said magnet, overcoming the resistance of a fluid." On the same day will expire patent No. 740, granted to Solignac and Co., for "Improvements in electric lamps or regulators, and in generators for use therewith." One of the inventions claimed is the use of glass rods in an arc lamp, so arranged that by the gradual melting of the rods the carbons shall feed together at the proper rate.

The Filing of Trade Catalogues at the Patent Office.—In *The Electrician* of October 18, 1895, some correspondence appeared on this subject, and the attention of the London Chamber of Commerce was called to the matter. The following communications have passed between the London Chamber of Commerce and the Patent Office:—

To Sir Henry Reader Lack, Comptroller-General of Patents. January 27, 1896.

SIR: The attention of this Chamber has been called to the fact that the Librarian of the Patent Office of the United States of America is making a collection of illustrated and other trade catalogues, price lists, circulars and other similar publications for reference by those instituting inquiries in regard to patents, designs and trade marks, or making use of the Patent Office library. I am desired to say that in the opinion of this Chamber such a collection of records in your department would be exceedingly valuable, and am directed to bring the suggestion before the authorities of H.M. Patent Office as one which it would be well to adopt. By this means there would be permanently preserved an enormous amount of extremely useful material, which might on occasion elucidate the meaning of many trade terms and usages. If such a collection and filing were adopted by the Patent Office it would no doubt be extremely serviceable, and be largely resorted to by those interested in patents, designs and trade marks. I am desired to express the hope that this suggestion will receive the careful consideration of the authorities of H.M. Patent Office, and I shall be glad to learn their decision in the matter.

(Signed) KENRIC B. MURRAY (Secretary).

To the Secretary, the London Chamber of Commerce.

SIR: I beg to acknowledge the receipt of your letter of the 27th inst., suggesting, on behalf of the London Chamber of Commerce, that a collection of illustrated and other trade catalogues, price lists and similar publications should be made and filed in the Patent Office Library, and in reply to inform you that the nucleus of such a collection was formed some 20 years ago, and has since that date been gradually extended. In view, however, of the suggestion of the London Chamber of Commerce, I shall be happy to consider how far it may be possible to render this collection more complete and to make it more easily accessible for public reference.

(Signed) H. READER LACK (Comptroller-General).

German Glow Lamps.—Says the *Elektrotechnische Zeitschrift*, in its issue of February 6th, "We have received, from an authoritative source, a letter, in which allusion is made to the campaign which English lamp manufacturers have started against the German product in their technical journals:—

"What enormous damage has been done by the remarks of the Commission of the Association of Representatives of German Electric Supply Companies, appointed to draw up rules in connection with the supply of glow lamps, is shown by the advertisements now appearing in English technical journals, and which, in view of the existing wave of public feeling, will not fail of effect. Although this is not the place to go fully into the matter, it may be permitted to remark that the mischief to the industry would have been avoided had this important question been solved by the Verband Deutscher Elektrotechniker, or any other responsible body. May it be a lesson to all who are inclined to dispose light-heartedly of things which should be left to the judgment of those thoroughly acquainted with the matter! A not very important London company, consisting mostly of Germans, employs in the most audacious manner a literal translation of those remarks for the purpose of running down the German product in the eyes of their pseudo-countrymen."

The endeavours of English manufacturers to stifle German competition is comprehensible. Under the rule of a monopoly which was based on the very patents which the owners successfully fought in other countries, the price of lamps in England up to about a year ago could be kept at a height that was out of all proportion to the prime cost. This, without a doubt, has caused great difficulty in the development of the electric light in England. In Germany, under the influence of free competition, great progress was made in the manufacture of lamps, and after continuous improvement we have been successful in producing a lamp which in no respect is surpassed by any foreign make. Naturally, the importation of German lamps

Digitized by Google

into England is inconvenient to the manufacturers there. The representatives of electricity works by the publication of their deliberations never dreamt of forging weapons which would be used against native products, as their remarks and observations did not apply in particular to German lamps, but to glow lamps in general; lamps imported from Austria, Holland, Sweden, &c. It was only intended to stimulate the drawing up of standard rules with regard to glow lamps. That the drawing up of such rules is best left in the hands of the Verband is pointed out in the letter quoted above, as in that body all interests are represented, from the combined action of which a useful result might be hoped for."

The Dolbear Patent for Hollow-Core Air-Dielectric Cables. Before the Judicial Committee of the Privy Council on Tuesday (present Lords Shand, Watson and Davey and Sir Richard Couch) motion was made to fix a day to hear the petition for the prolongation of Dolbear's Patent for IMPROVEMENTS IN ELECTRICAL CABLES, No. 1,368, of March 21, 1882. The Committee appointed March 18th as the day on which to take the case. The following is an abstract of this important patent :—

My invention relates to electrical cables and is designed to provide cables of greater efficiency than those heretofore constructed for the transmission of messages or signals. In electrical cables heretofore constructed the conductor is coated or covered with a non-conductor (which is usually a substance of high specific inductive capacity) and the amount of surface contact between the conductor and non-conductor is at its maximum or nearly so. The rapidity with which a cable may be worked depends upon the rate at which it may be charged or discharged, and this rate of charge and discharge depends upon the specific inductive capacity of the material used as a coating for the conducting wire of the cable and upon the extent of surface contact between the conductor and the non-conductor by which it is insulated, other things being equal; now according, to my invention I reduce this contact to a minimum; and thereby accelerate the working of the conductor. The best possible form of cable would be a non-conducting pipe or tube with the conducting wire held centrally in it, the outer surface of the wire being in contact with nothing but the air filling the pipe ; and the nearer the actual cable approximates to this ideal cable the better will be the result. I therefore construct my cable with a central conductor (of one or several strands) surrounded by a tube whose inner diameter is considerably greater than the outer diameter of the conductor. Around this is twisted in an open spiral, a cord of cotton or the like, preferably hard twisted. Its office is to prevent the collapse of the pipe by supporting it at intervals along its interior, and when the pipe is sufficiently strong I dispense with this spiral for there is obviously more surface contact between the conductor and the spiral than there would be between the conductor and the inner surface of the pipe were the spiral omitted. I find it advantageous to manufacture my improved cable as follows—that is to say, the conductor is composed of copper wires as usual, twisted into a strand. The cord is wound spirally around the conductor, as it is fed along by proper mechanism ; and the tube or pipe is formed of several thicknesses of paper rendered waterproof, and cemented by india-rubber cement to ensure strength and toughness after the spiral is put upon the conductor. The claim is :—In an electric cable the hollow core or tube *d* containing the conductor *a*, whose diameter is less than the inner diameter of the core *a* substantially as, and for the purpose described.

'Bus Bars and Cables in the Niagara Power House.—A detailed description of these is given in the *Electrical Engineer* of New York of November 20th. About 1,200ft. of cable has been used in carrying the current from the dynamos to the board, after test under 45,000 to 48,000 alternating volts. There are 427 copper wires in the cable, consisting of 61 strands laid up in reverse layers, each strand consisting of seven wires. Next to the strand of copper is a wall of rubber $\frac{1}{4}$in. thick, double-coated. Over this is wrapped absolutely pure rubber, imported from England and known as "cut sheet." Then come two wrappings of vulcanisable Para rubber ; over that a wrapping of "cut sheet," and on top of that two more rubber coats. It is then taped, covered with a substantial braid and vulcanised. This cable weighs just over 4lb. to the foot, of which 3lb. are copper and 1lb. is insulation. The Niagara 'bus bars are eight in number, and 50ft. 4in. long, each having 10 offsets. The bars are made up of five components. The centre and the intermediate components are seamless copper tubes made up by drawing a $\frac{1}{4}$in. tube over another of the same size, the wall being $\frac{1}{2}$in. thick. The end components are solid bars of copper $1\frac{1}{4}$in. thick. The diameters of these great 'bus bars are as follows: Centre component, 8ft. long, 3in. outside diameter, 2in. inside. Intermediate component, 8ft. 6in. long each (two of them), 2in. outside diameter, 1in. inside. The ends, solid (two of them), 10ft. 11in. long each, $1\frac{1}{4}$in. in diameter. These bars are screwed together, with a length of entrance of 10in., then thoroughly soldered, and the entire outside tinned. There are no corners or projections whatever. Each component has two offsets, consisting of split sleeves accurately fitted, screwed together with long-headed screws, the heads filed off flush, and finally soldered to the bar. The elbows, being the terminals of the cables, are taper-fitted to the ends of the offsets, and fastened with a counter-sunk screw. The entire system is then insulated by wrapping a perfectly pure rubber compound and pure rubber in alternate layers, building up a wall $\frac{4}{32}$in. in thickness ; then covered with thin rubber-covered cotton tape, and wrapped outside with a rubber-covered drill tape. The bars were vulcanised in a special apparatus. The effective pressure guaranteed on the cables is 10,000 volts alternating. The $\frac{1}{4}$in. wall when tested under water broke down at about 48,000 volts, and cables having a wall of $\frac{5}{16}$in. and $\frac{3}{8}$in. withstood a test of 52,000 volts, this being the extreme range of the testing apparatus, contact being kept on for one minute without effecting any perforation.

The Alternate-Current Transformer.—At the opening of his fourth and last Cantor lecture, Dr. Fleming continued the subject of transformer measurements. The Wheatstone bridge method was, he said, applicable to the measurement of the primary copper resistance (the secondary being short-circuited meanwhile to render the self-induction of the primary negligible). To measure the copper resistance of the secondary, on the other hand, the fall of potential method had to be used. As the temperature coefficient of the copper usually employed in transformer coils was about 0·4 per cent. per degree Centigrade, we can accurately determine the rise of temperature of a loaded transformer by ascertaining its cold and hot copper resistances. Having determined and plotted the *total* loss in a transformer at various loads, and its copper losses at these loads, we can deduce the hysteresis loss, since it is practically the difference between the ordinates of the curves of total and copper loss. The secondary drop of a loaded transformer, usually amounting to about three or four volts, due to magnetic leakage and the C R losses, was then discussed ; and a method of accurately measuring the same was described in which the indications of an electrostatic voltmeter were the actual dropped volts from which, after the C R losses had been deducted, the drop due to magnetic leakage could be deduced. Dr. Fleming then alluded to Mr. Mordey's ingenious method of detecting magnetic leakage by placing two thermometers, one mercury and one spirit, within the stray alternating field. As the former has eddy currents generated in it, and the latter not, the difference of the temperature indications of the two thermometers is a measure of the magnetic leakage. Magnetic leakage was, the lecturer pointed out, sometimes deliberately encouraged, as in the T.H. and Ferranti transformers, in which it is desired to obtain a constant current from a constant potential. Dr. Fleming then dealt with the time increase in the core loss of transformers, first pointed out by Mr. G. W. Partridge in *The Electrician* of December 7, 1894. The cause of this phenomenon was somewhat obscure, but it was shown by Mr. Mordey to be apparently due to the heating of the transformer rather than to any magnetic cause. He (the lecturer) had come across an instance in which the core loss had increased to four times its original value in a short time. The danger (due to electrical resonance) of suddenly switching transformers on to and off high-pressure circuits possessing appreciable inductance and capacity was then emphasised, and several instructive mechanical analogues were exhibited. The lecturer stated that almost all concentric cables he had tested had come out with a capacity of about one-third of a microfarad per mile. The specific inductive capacity of the impregnated paper used by the British Insulated Wire and other companies was about three, as compared with four for india-rubber. The distribution of alternate currents in thick conductors was then touched upon; with currents of about 100 ∽, solid copper conductors of more than $\frac{1}{4}$in. radius were useless. The lecturer concluded with an explanation of the utilisation of clock-face diagrams for the solution of alternate-current problems. The following formula for determining the condenser current in a circuit having a capacity C farads, and traversed by a current of frequency n, at a pressure V volts, was given amongst many others. Current $= C/10^6 \times V \times 2\pi n$.

THEORY AND CALCULATIONS OF ASYNCHRONOUS ALTERNATE CURRENT MOTORS.

BY A. HEYLAND (BUDAPEST).

PART I.—POLYPHASE MOTORS.

I.—*Deduction of Theory*

This method of calculation is based upon the practical adaptations of certain peculiar results, at which the author arrived in submitting the phenomena of mutual induction to a graphical treatment. The research was published in the *Elektrotechnische Zeitschrift*, 1894, p. 561, No. 41. This graphical treatment of induction phenomena will prove particularly applicable to the purpose in all cases in which we have to deal with a considerable straying of the lines of force; for the method enables us to group the rather complex stray field phenomena in a very simple and lucid manner. As the action of polyphase motors is chiefly determined by these stray lines, the idea naturally suggested itself to base a method of predetermination upon such considerations. The attempt has proved quite successful. The relations between the various quantities—dimensions of iron, power factor, load limit, &c.—can clearly be established, and the calculations of the polyphase motor be expressed in a few simple formulæ.

A few introductory explanations. The *polyphase motor* has been treated as a *transformer with rotating field*. The exciting armature forms the inducing or primary circuit, the short-circuit armature the induced or secondary circuit. This parallel between motor and transformer is permissible, under the supposition that the total reaction of the polyphase currents produces a rotatory field of constant intensity. In that case we may substitute for the primary or secondary alternating cur-

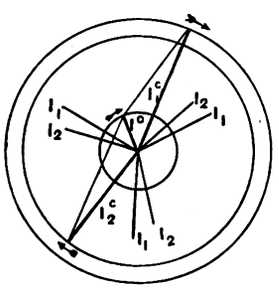

FIG. 1.

rents, whose amplitudes may be $I_1\ I_1\ I_1$ or $I_2\ I_2\ I_2$, equivalent continuous currents I_1^c or I_2^c, whose directions will revolve in the motor with the speed of the rotatory magnetic field (*see* Figs. 1 and 2).

The directions of $I_1\ I_1\ I_1$ and $I_2\ I_2\ I_2$ determine at the same time the positions of the primary and secondary coils, and hence also the relative positions of the two armatures. We recognise that the momentary positions of the two armatures do not influence the induction, since each of the two systems reacts upon the other like a uniform circuit. I_1^c and I_2^c then combine to form the magnetising current I^c, which produces the rotatory field. The velocity of the field we will call V, that of the short-circuit armature, which we assume to be the revolving part, v. Thus we gain a clear idea of the effects of electrical induction and mechanical rotation. As long as the armature is at rest, its coils, as well as the coils of the exciting armature, will be cut by the lines of force of the field with the velocity V. These lines will induce currents in the short-circuit armature, and impart a turning moment to it. The frequency of the induced currents in the armature is the same as in the primary circuit, which we will call p_1. When the armature yields to the turning moments with the velocity v, the armature coils will more and more recede from the lines of force, and they will only be cut with the velocity $V - v$.

The frequency of the armature currents will decrease. Let it become p_2, so that $\frac{p_2}{p_1} = \frac{V - v}{V}$. The E.M.F. in the armature will likewise decrease. As the resistance of the coils remains constant, the current relations will be the same as if we let the armature remain at rest, which would mean, let the motor act as a transformer, while increasing the armature resistance, this increase to be in the inverse ratio of p_2/p_1; that is to say, we add an external armature resistance which has the ratio $(p_1 - p_2)/p_2$ to the internal resistance. The internal losses will in both cases be the same. The mechanical work done by the motor under these conditions will be equal to the useful electrical work which a transformer of the same arrangement would perform in its external circuit.

These considerations demonstrate that, under the suppositions we have made, the polyphase motor may be regarded as a transformer. It may be interesting to point out in this place that the accuracy of the calculations in question does not, as might be assumed, depend upon the degree of approximation of the current curve to a sine curve. The accuracy is only influenced by the constancy of the combined effects of the polyphase currents in the motor.

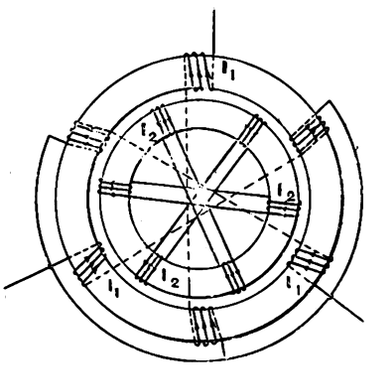

FIG. 2.

There is an essential difference between polyphase motors and our modern transformers. A well-built transformer with uniformly distributed coils has practically no self-induction in its several circuits. If we connected the primary and secondary coils, which we will suppose to be of equal number, opposed in series, they would behave like a bifilar resistance, and would not produce any phase difference in the circuit. This means that at full load, when the secondary ampere-turns of the transformer become almost equal to the primary ampere-turns, the phase shifting may practically be neglected as of no account. This circumstance renders transformer calculations very simple.

In the motor, the primary and secondary coils lie on separate armatures, with iron and air intervening. Hence there is

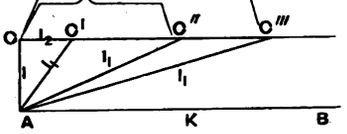

FIG. 6A.—Diagram for a Transformer without Stray Field, $\tau = 0$. (The Modern Transformer.)

self-induction in each single conductor, and the E.M.F. of this self-induction increases with the current intensity in both conductors. The result is that the phase difference between the secondary current I_2 and the E.M.F. grows continuously. The phase difference between the primary current I_1 and the P.D. at the terminals, K will at first decrease at a slower rate than in the case just mentioned; it will attain a *minimum*, and then rise rapidly.

For the modern transformer the current relations may, if we neglect hysteresis and Foucault currents, be represented in the well-known manner of Fig. 6A, lower down. I, the combined effect of I_1 and I_2, constitutes the magnetising current. At right angles to the magnetisation and the magnetising current lies the E.M.F., and, with sufficient accuracy for practical purposes, also the potential difference at the terminals, K. $I_2 = O C'$, $O C''$, $O C'''$ falls in the direction of the E.M.F., and, therefore,

Digitized by Google

also perpendicular to I = A C. I_1 results then, for every load, as the hypothenuse of the right-angled triangle whose cathetes are I and I_2. Within the limits of constant magnetisation, the point C′ C″ C‴ . . . will therefore move in a horizontal line, parallel to the potential difference K = A B at the distance I.

For the polyphase motor, the difference of phase between I_2 and the E.M.F. increases owing to the stray field with the load, and the point C′ C″ C‴ moves on a curve which must turn upwards (Fig. 6B). In that figure C″ marks the minimum of phase difference between I_1 and the P.D. at the terminals K. The *minimum of phase difference* between the *primary current and the P.D. at the terminals* affords, however, as will be shown, a direct measure for the *quality and the suitability* of the polyphase motor. The first point to be discussed is the relation between this minimum and the dimensions of the motor.

The article alluded to in the first lines of this paper showed how the dependence of the variable electrical quantities of a transformer (polyphase motor), the amplitudes of the primary voltage, secondary E.M.F., and current intensity, and their phase differences, upon the change of load, can be represented diagrammatically. The primary difference of potential, whose amplitude and phase should be constant for all loads, is represented by the constant base of the diagram, while the diverse vectors mark amplitude and phase of the other quantities. A very simple law was established. *The extremities of these vectors, which are the movable corners of the diagram, describe circles when the loads of the transformer vary within the limits of constant permeability of the iron.* These diagrams

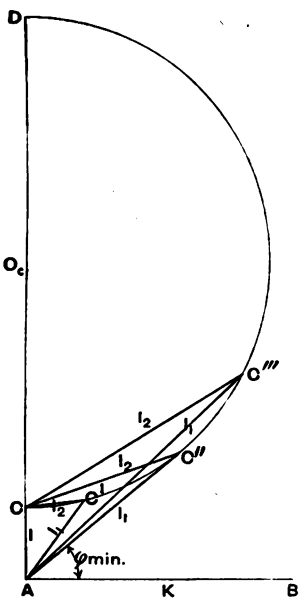

FIG. 6B.—Diagram for a Transformer with Stray Field, $\frac{A C}{C D} = (1+\tau)^2 - 1$.
(The Polyphase Motor.)

are reproduced in Figs. 3 and 4. The coefficients of induction, as used in the original deduction, have not been applied here as unsuitable for practical purposes. Nor have, for the present, the losses by hysteresis and Foucault currents been taken into consideration; these losses would exercise no influence upon the character of the diagram. In order to simplify the graphic treatment, the ratio of transformation has been assumed as 1 : 1. If any other ratio, $s_1 : s_2$, is to be employed, the secondary quantities have to be reduced with the help of the following coefficients:—

For the secondary current intensity, $\frac{s_1}{s_2}$,

" " tension and E.M.F., $\frac{s_2}{s_1}$,

" " resistance, $\frac{s_2^2}{s_1^2}$.

Fig. 3 represents a transformer without stray field, in which all the lines of force enclose primary and secondary coils. Approximately this illustration applies to the modern transformer. In Fig. 4 there is a stray field. Not all the lines of force enclose both coils uniformly; part of the lines enclose only primary, or only secondary coils. In Fig. 3:

K is the primary difference of potential at the terminals.
E the E.M.F., both of the primary and the secondary circuit, as the ratio of transformation is 1 : 1.
I_1 the intensity of the primary current.
I_2 the intensity of the secondary current.
I the combined effect of I_1 and I_2, *i.e.*, the magnetising current.
W_1 the primary resistance.
W_2 the secondary resistance.

In polyphase systems these same letters refer to one phase.

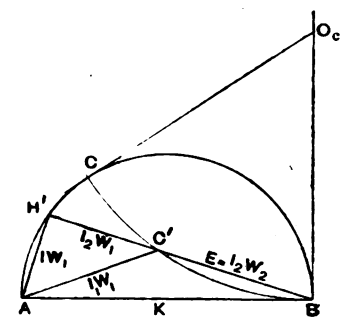

FIG. 3.—Diagram of the Relations between the Potential, the E.M.F., the Current and the Phase Difference in a Transformer without Stray Field. (The Modern Transformer.)

In the primary circuit the potential difference K = A B at the terminals is balanced by the back-electromotive force E = B C, and by the effect of resistance $I_1 W_1 = A C'$.

In the secondary circuit the current I_2 is opposite in direction to E, and $I_2 W_2 = E = B C'$.

If now B C′ is produced until it cuts the semicircle on A B in H′, the triangle A C′ H′ will indicate the directions of I_1, I_2 and I. I_1 lies in the direction of $A C' = I_1 W_1$; I_2 in the direction of C′ H′, the production of E; I in the direction of A H′, which is at right angles to B C′ = E, since the E.M.F. is perpendicular to the magnetisation. As now I is the resultant of I_1 and I_2, these three currents must correspond to a closed

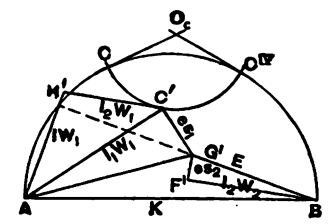

FIG. 4.—Diagram of the Relations between the Potential, the E.M.F. the Current and the Phase Difference in a Transformer with Stray Field. (The Polyphase Motor.)

triangle whose sides represent the three quantities in the ratio —A C′ : C′ H′ : A H′ = $I_1 : I_2 : I$.

As, further, A C′ = $I_1 W_1$, and
C′ H′ = $I_2 W_1$,
A H′ = $I W_1$,
we obtain A C′ = I_1 in the measure W_1,
C′ H′ = I_2 in the measure W_1,
A H′ = I in the measure W_1.

The diagram finally gives us the ratio

$$W_2 : W_1 = I_2 W_2 : I_2 W_1 = B C' : C' H'.$$

W_1 is constant, W_2 variable; hence the ratio $W_2 : W_1$ variable. When we alter this ratio—*i.e.*, when we change the load of the transformer—the shape of the diagram will also change, and it has already been demonstrated that, within the limits of constant permeability, the points C′ and H′ will move uniformly on the inscribed circles. The limit signifies, as long as the magnetisation, and therefore also the E.M.F., remain proportional to the magnetising current, or as long as the ratio E : I :: B C′ : A H′ is constant.

Digitized by Google

C′ and H′ coincide at C, when I_2 becomes = 0, and $W_2 = \infty$.

The triangle A B C is the diagram of open transformers.

At B, W_2 becomes = 0; $I_2 = I_1$, that is to say: For the theoretical case $W_2 = 0$, the diagram is reduced to the straight line A B, with which $I_2 W_1$ and $I_1 W_1$ coincide.

The points C and B lie on a semicircle described on A B as diameter. The centre of the circle on which C′ moves is determined as intersection of the tangents to the semicircle drawn at B and C.

In Fig. 4 we find the same quantities as in Fig. 3, and besides those due to the stray field—the E.M.F. of self-induction of the primary circuit e_{s_1}, and of the secondary circuit e_{s_2};

e_{s_1} is at right angles to I_1 and causes I_1 to lag behind the resultant of K and E;

e_{s_2} is at right angles to I_2 and keeps it behind E.

This type of graphic representation is well known.

The triangle A C′ H′ again represents the three currents I_1, I_2, I, and we have

$$I_1 W_1 = A C'$$
$$I_2 W_1 = C' H'$$
$$B F' = (I_2 W_2)$$
$$I W_1 = A H' \text{ (perpendicular to E)}.$$

The corners F′ G′ C′ H′ of this diagram likewise describe circles within the limits of constant permeability, as has also been demonstrated in the article in the *Elektrotechnische Zeitschrift*. This paper confines itself to the circle which is the locus of C′. The loci of F′ G′ H′ have not been marked. The C′ circle is determined similarly as before in Fig. 3. The circle cuts the semicircle on A B in two points, C and $C^{IV.}$ (Fig. 4A), so that triangle A B C is the diagram for $W_2 = \infty$, *i.e.*, of the transformer without load. Triangle A B $C^{IV.}$ depicts the theoretical case $W_2 = 0$. The centre of the circle

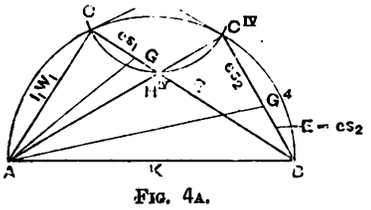

FIG. 4A.

is again the intersection of tangents drawn to the semicircle on A B at the points C and $C^{IV.}$. In the just mentioned case, $W_2 = \infty$, when the triangle A B C is the diagram, we have $I_2 = 0$; $I_2 W_1$ and I W_1 coincide with A C, *i.e.*, $I = I_1$; the E.M.F. E, at right angles to I, and the self-induction e_{s_1} at right angles to I_1, coincide likewise as regards direction; and it results,

$$B C = B G + G C = E + e_{s_1}.$$

In the diagram, triangle A B $C^{IV.}$, W_2 is = 0, therefore $I_2 W_2 = 0$. We see, now, from Fig. 4, that in triangle B E′ G′, e_{s_1} and E must coincide, whilst the infinitely small line $I_2 W_2$ would be perpendicular to e_{s_2}; E falls in the direction perpendicular to $I_1 W_1$ and I W_1, and hence also $I_2 W_1$ in the direction of $I_1 W_1$ and I W_1; e_{s_1} is at right angles to $I_1 W_1$, and has the direction of e_{s_2} and E. The current triangle is hence reduced to the straight line A $H^{IV.}$ C^{IV}, and

$$A C^{IV.} = I_1 W_1,$$
$$C^{IV.} H^{IV.} = I_2 W_1,$$
$$A H^{IV.} = I W_1,$$

while the electromotive forces would be indicated by the line B $C^{IV.}$, which forms the other side of the triangle A B $C^{IV.}$. Here we have

$$B G^{IV.} = E = e_{s_2};$$
$$G^{IV.} C^{IV.} = e_{s_1}.$$

There is a simple connection between the triangles A B C and A B $C^{IV.}$.

The magnetising current generates the main magnetic field, which we will designate by H. Each of the currents I_1 and I_2 generates a number of stray fields, which we summarise as the primary stray field h_1, and the secondary stray field h_2. We know that E is proportional to H, e_{s_1} proportional to h_1, and e_{s_2} to h_2, or

$$E : e_{s_1} : e_{s_2} = H : h_1 : h_2 \quad . \quad . \quad . \quad . \quad (1)$$

For constant permeability we have further: H varies proportionally to I, h_1 to I_1, and h_2 to I_2. The fields H_1, h_1, h_2 are not as the currents I, I_1, I_2; we have to consider the magnetic resistances of the various fields before we can settle their mutual relations. We may write

$$H : h_1 : h_2 = I : \tau_1 I_1 : \tau_2 I_2, \quad . \quad . \quad . \quad (2)$$

where τ_1 and τ_2 remain constant for constant permeability, and may be ascertained from the dimensions of the iron, &c.; lower down, when we come to the practical part, the τ will be further defined. Equation (2) gives

$$\frac{h_1}{H} = \tau_1 \frac{I_1}{I} \quad . \quad . \quad . \quad . \quad . \quad . \quad (3A)$$

$$\frac{h_2}{H} = \tau_2 \frac{I_2}{I}. \quad . \quad . \quad . \quad . \quad . \quad . \quad (3B)$$

Further, from (1)

$$\frac{e_{s_1}}{E} = \tau_1 \frac{I_1}{I}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (4A)$$

$$\frac{e_{s_2}}{E} = \tau_2 \frac{I_2}{I}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (4B)$$

or

$$\frac{e_{s_1}}{I_1} = \tau_1 \frac{E}{I}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (5A)$$

$$\frac{e_{s_2}}{I_2} = \tau_2 \frac{E}{I}. \quad . \quad . \quad . \quad . \quad . \quad . \quad (5B)$$

Now in $\triangle$ A B C

$$\frac{B C}{A C} = \frac{B G}{A C} + \frac{G C}{A C} = \frac{E}{I_1 W_1} + \frac{e_{s_1}}{I_1 W_1};$$

but $I_1 = I = A C$,

hence:
$$\frac{B C}{A C} = \frac{E}{I W_1} + \frac{e_{s_1}}{I_1 W} = \frac{E}{I W_1} + \tau_1 \frac{E}{I W_1},$$
$$\frac{B C}{A C} = \frac{E}{I W_1}(1 + \tau_1).$$

Secondly, in triangle A B $C^{IV.}$

$$\frac{B C^{IV.}}{A C^{IV.}} = \frac{B G^{IV.}}{A C^{IV.}} + \frac{G^{IV.} C^{IV.}}{A C^{IV.}} = \frac{E}{I_1 W_1} + \frac{e_{s_1}}{I_1 W_1}.$$

As now here $E = e_{s_2}$, it follows from (4B) that

$$\tau_2 \frac{I_2}{I} = \frac{e_{s_2}}{E} = 1, \text{ and } I_2 = \frac{I}{\tau_2},$$

Further,
$$I_1 = I + I_2$$
$$I_1 = I + \frac{I}{\tau_2} = I\left(1 + \frac{1}{\tau_2}\right).$$

Substituting,

$$\frac{B C^{IV.}}{A C^{IV.}} = \frac{E}{I W_1 \left(1 + \frac{1}{\tau_2}\right)} + \frac{e_{s_1}}{I_1 W_1} = \frac{E}{I W_1}\left(\frac{1}{1 + \frac{1}{\tau_2}} + \tau_1\right);$$

$$\frac{B C^{IV.}}{A C^{IV.}} = \frac{E}{I W_1}\left(\frac{\tau_2}{1 + \tau_2} + \tau_1\right).$$

By dividing we obtain an equation containing the four quantities:—

$$\frac{\frac{B C^{IV.}}{A C^{IV.}}}{\frac{B C}{A C}} = \frac{\frac{\tau_2}{1 + \tau_2} + \tau_1}{1 + \tau_1} = \frac{\tau_1 + \tau_2 + \tau_1 \tau_2}{1 + \tau_1 + \tau_2 + \tau_1 \tau_2}. \quad . \quad . \quad (6$$

We shall see that τ_1 and τ_2 are very small fractions; we may hence replace them by τ, as defined by the equation

$$\tau = \frac{\tau_1 + \tau_2}{2}. \quad . \quad . \quad . \quad . \quad . \quad . \quad (7)$$

We then obtain finally

$$\frac{\frac{B C^{IV.}}{A C^{IV.}}}{\frac{B C}{A C}} = \frac{2\tau + \tau^2}{1 + 2\tau + \tau^2} = \frac{(1 + \tau)^2 - 1}{(1 + \tau)^2}. \quad . \quad . \quad (8)$$

II.—*Practical Application of the Deduction.*

By applying in practice the formulæ deduced we can deal with polyphase motor problems in the same simple manner in which Kapp's graphic method solves transformer problems. A few lines suffice to depict the current relations.

Digitized by Google

The magnetisation is kept low in practice; the internal resistances W_1 and W_2 are also chosen as small as possible. The line A C (Fig. 4A), which represents the magnetising current as expressed in W_1, will hence be short compared to A B = K, and the point C will fall close to A. We may, therefore, regard A C as at right angles to A B, and the tangent at C, which contains the centre of the circle O_c, may also be considered as a perpendicular; thus C O_c at right angles to A B. This has been done in Fig. 5.

Under these conditions, point $C^{IV.}$ will shift considerably to the left. We now produce B $C^{IV.}$ and C O_c until they intersect at D. The circle described about O_c as centre will pass through D, C D being a diameter. We have then

$$\frac{A'B}{AD}=\frac{BC^{IV.}}{AC^{IV.}}, \text{ and } \frac{AB}{AC}=\frac{BC}{AC};$$

further, from (8),

$$\frac{AC}{AD}=\frac{\frac{AB}{AD}}{\frac{AB}{AC}}=\frac{\frac{BC^{IV.}}{AC^{IV.}}}{\frac{BC}{AC}}=\frac{(1+\tau)^2-1}{(1+\tau)^2},$$

and

$$\frac{AC}{CD}=(1+\tau)^2-1. \quad . \quad . \quad . \quad . \quad . \quad (9)$$

Equation (9) signifies: The ratio between the *diameter* C D and the *magnetising current* I is determined by τ. Fig. 6B

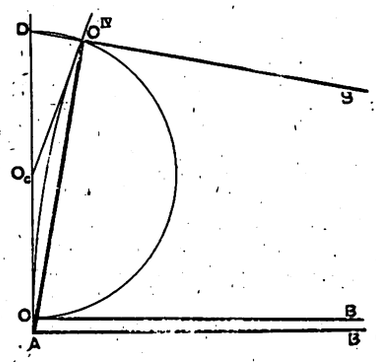

Fig. 5.

contains the essential parts of the diagram. The primary tension K falls in the horizontal; at right angles to it, the magnetising current I = A C, and the diameter of the circle C D. The latter results, as I = A C, from

$$CD=\frac{AC}{(1+\tau)^2-1}.$$

The influence of the stray fields we recognise by comparing this figure with a Kapp diagram, Fig. 6A. In this figure the magnetising current I = A C has been assumed as constant. The E.M.F., and practically also the P.D., at the terminals K, indicated by the base A B, will be at right angles to A C. I_2 = C′ C, C″ C, C‴ C . . . falls in the direction of the E.M.F., and I_1 results as hypothenuse A C′, A C″, A C‴ of the right-angled triangle whose sides are I and I_2.

With continuously growing I_2, the difference of phase between I_1 and K will soon become very slight.

In Fig. 6B, A C = I again stands for the magnetising current at no load. For heavier loads this current would change its direction, but this circumstance little concerns the present considerations.

With increasing I_2 the lag of I_2 will increase, and the points C′ C″ C‴ . . . will travel further upwards, moving the circle just constructed. The first case (Fig. 6A) may directly be deduced from the second case (Fig. 6B). In the first case we have no stray fields, h_1 and h_2, and τ becomes zero, so that the diameter $CD=\frac{AC}{2\tau}=\infty$. The circle passes into the straight line C C′ C″ . . . parallel to A B (Fig. 6A). The diagram (Fig. 6B) hence demonstrates how the difference of phase between the current intensities and the P.D. varies with the load, owing to the magnetic leakage. The lag of I_2 continues to increase with increasing load.

* τ^2 being very small, therefore $(1+\tau)^2=1+2\tau$ and $CD=\frac{AC}{2\tau}$.

The difference of phase ϕ between I_1 and K is the angle C′ A B, C″ A B . . . We recognise that ϕ diminishes at first, but less rapidly than it would do without any leakage; it then attains its minimum at C″, rapidly to increase again afterwards.

The work done upon each of the m primary circuits is K . $I_1 \cos\phi$; the total energy absorbed by the motor is the total work done upon these circuits, $A_1 = m \,.\, K \,.\, I_1 \cos\phi$. This $\cos\phi$ is known as the power factor. $I_1 \cos\phi$ represents that portion of the current which coincides with the P.D., and does work; it is the useful current. The other component $I_1 \sin\phi$ does not perform work. The relation between these quantities is expressed by $\cos\phi=\frac{\text{useful current}}{I_1}$.

As a rule it will be advisable to choose the *normal load* so that the ratio $\frac{\text{work done}}{I_1}$ is a maximum, when $\frac{I_1\cos\phi}{I_1}=\cos\phi$ itself will be a maximum. For this case, ϕ is a minimum The condition is fulfilled in Fig. 6B for ϕ = C″ A B when C″ A is tangent to the circle. We will designate the maximum power factor by $\cos(\phi_{min})=(\cos\phi)_{max}=f$.

(To be continued.)

HIGH-PRESSURE PROTECTED-CONTACT SWITCH.

In the course of one of his recent Cantor lectures Dr. Fleming exhibited a varied assortment of high-pressure switches and fuses, and amongst others a double-pole, high-pressure, "protected-contact" switch, made by the British Thomson-Houston Company.

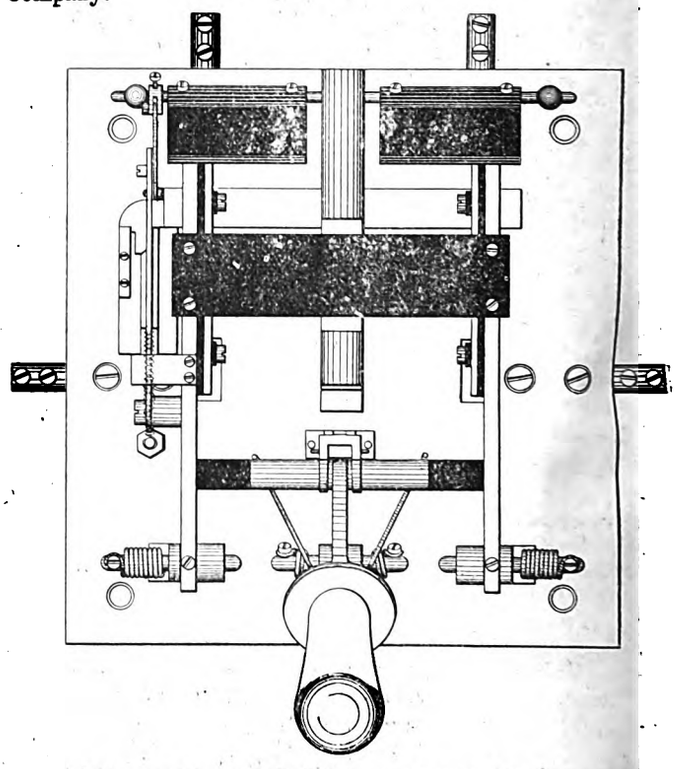

Fig. 1.—Thomson-Houston High-Pressure Protected-Contact Switch. Front view, with circuit-closed.

A front elevation of the switch with circuit closed is given in Fig. 1, and a side elevation with circuit opened in Fig. 2. The base of the switch is a block of marble about 10in. square and 1in. thick. The two conductors, it will be seen from Fig. 1, are led in on either side to bare screw-terminals, and out at the top. The two arms of the switch are 7½in. long, and 5½in. apart, insulation being afforded by two 1in. lengths of vulcanite. The two lower jaws of the switch are protected from accidental cross contacts when the switch is open by the switch frame itself, and by the interposition of a wall of marble (*see* Fig. 2) 1in. high and ⅝in. thick. The two top jaws are similarly separated, but to still further ensure freedom from accidental cross contact they are covered by vulcanite

Digitized by Google

shutters or shields 2½in. by 1½in. by ¼in. thick, lined with mica. These two shutters are fastened on to a common spindle actuated by a brass piece movable around a projection on the side of one of the arms of the switch (*see* Fig. 2). This brass piece slides, as the switch is depressed, in a slotted carriage until it comes in contact with an end stop; as the switch is still further depressed this carriage is pushed along against the backward pull of a powerful spring, rotating the shutter spindle by means of a bell-crank lever, and raising the shutters. At the moment the circuit is closed, a stud on the brass piece is released from under a cam, the brass piece rides up over the end of the sliding carriage, this is immediately pulled back by the spiral spring, and the shutters are pulled down onto the top of the switch arms. On depressing the handle and raising the switch arms free from the shutters, these are immediately pulled further down by the spiral spring, this time covering right over the contact jaws sunk in the base beneath.

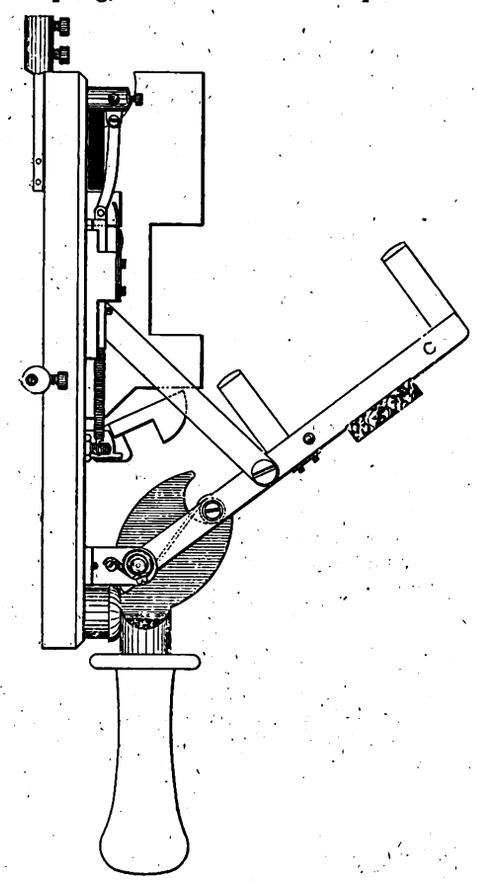

FIG. 2.—Thomson-Houston Switch. Side Elevation, Circuit opened.

THE REICHSANSTALT STANDARD WIRE RESISTANCES.*

BY K. FEUSSNER AND ST. LINDECK.

In 1888 investigations were commenced in the electrotechnical laboratory of the Reichsanstalt, with the object of constructing almost invariable standards of resistances suitable for practical use, and to obtain a surer foundation for electrical measurements of precision.

Upon this investigation many communications from the Reichsanstalt have been published.† In the *Wissenschaftl. Abhandl. der Reichsanstalt*, 2, S. 503 (Julius Springer, Berlin, 1895) is a comprehensive account of this research, from which the following is abstracted. For an account of the investigations upon "Metals for Standard Resistances," and the communication on the "Permanence of Wire Resistances," the original Papers must be referred to.

I.—THE CONSTRUCTION OF THE STANDARD RESISTANCES.

The standard resistances are intended in the first place for the standardisation and checking of other resistances. For this purpose the Reichsanstalt has constructed a series of single resistances which range from 0·0001 ohm, with a number of intermediate values, to 10,000 ohms. In addition to check measurements they are intended to serve other purposes, as, for example, ratios for Wheatstone's bridge, or as resistances for current measurement by the potentiometer. For the latter purposes there are particular forms of resistances, the so-called ratio coils (*see* below) and the large main resistances.* In the present communication the standard resistances of 0·1 ohm and upwards only are considered, which are constructed of wire. For the lower standard resistances a new form has recently been devised in which a number of thin plates, preferably of manganin, are used as the main resistance. A full description of these latter resistances will be given when greater experience has been obtained with the new forms.

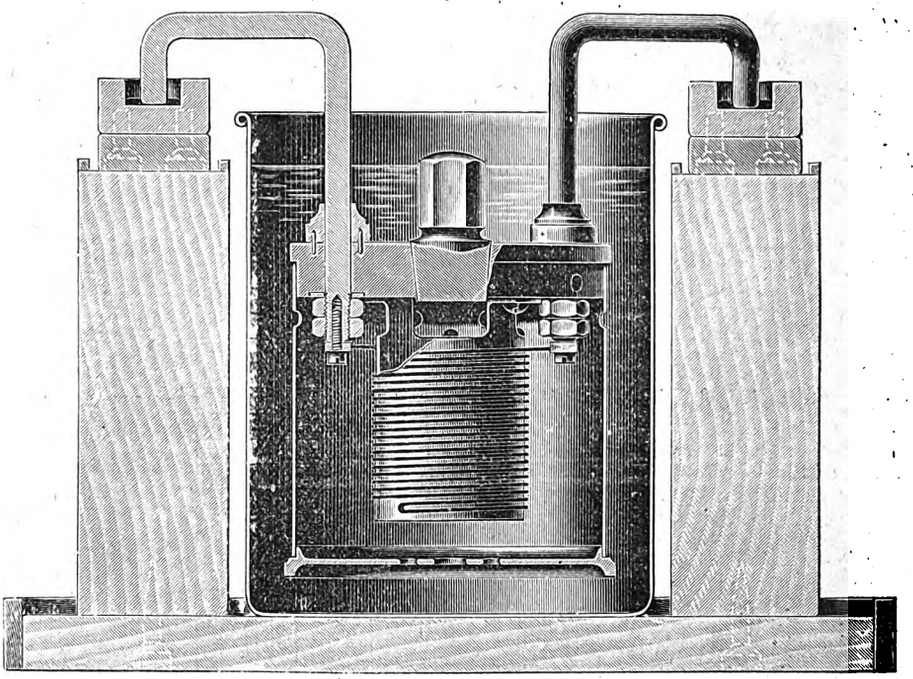

FIG. 1.—Reichsanstalt Standard Wire Resistance. Sectional Elevation.

Fig. 1 shows a standard resistance coil of 1 ohm, which is immersed in a paraffin oil bath in the usual manner. It hangs by the two leads from the mercury cups, and swings freely in the bath, so that the paraffin oil has free entrance on all sides. For the circulation of the liquid, the top, bottom and sides are perforated. The resistance wire, for reasons which are discussed in the original article, is, as a rule, of manganin. It is wound on a brass cylinder 4cm. in diameter in a single bifilar layer. For the 0·1 ohm standard a second wire having one-tenth of the section and ten times the length is joined in parallel with the main wire. This is for the purpose of enabling the value of the resistance to be more easily and accurately adjusted. The main wire is made approximately 1 per cent. higher than the final value of the resistance. An alteration of 1 metre in the length of the shunt is equivalent to one of 1mm. in the main wire.

For the connection of the ends of the coil with the leads the main wire is silver-soldered to the side of small square copper washers. These washers are screwed to the ends of the leads. The contact surfaces, having been previously tinned, are raised to the melting temperature by a soldering iron, while the screw is tightened up. This is the only connection which has been found sufficiently good for wires of less than four or five metres in length. If the wire is soldered directly to the copper leads, in course of time a marked alteration of the resistance results, as the solder alters its structure, and small crevices are formed round the soldered wire, which increase its working length. By this method of connection the advantage is secured that the resistance coil can be removed from the apparatus without destroying the adjustment.

The two terminals forming the working ends of the resistance lie in the copper blocks on each side underneath the bottom of

Digitized by Google

the mercury cups, in which the leads stand. To the resistance of the manganin wire, therefore, is added that of the two copper leads and of the mercury contacts. The latter is made very small, since the flat ends of the leads stand on the flat bottoms of the mercury cups. If these parts are well made and amalgamated, the variation of the contact resistance, on account of its small value, may be neglected. The resistance of the two leads together in the case of the 0·1-ohm coils is about 70, and for the 1-ohm coils about 140 microhms, and is in consequence so small that it does not sensibly affect the temperature coefficient of the whole apparatus; nor, when differences of temperature exist between the coil and the leads, do they appreciably affect the total resistance.

To prepare the resistance bobbin for the wire the ebonite cover is removed, and the bobbin covered with shellaced silk tape, and dried at 140°C. Then the double-white-silk-covered wire is wound doubled on itself, tied with silk thread, and covered with shellac varnish. The coil is then heated in a drying oven for 10 hours, at a temperature of 140°C. The shellac covering protects the wire during heating and in subsequent use, so well that no perceptible oxidation ensues. It also serves to hold the wire fast on the bobbin, so that no alteration of position can take place. From the long-continued heating the shellac becomes hard even at high temperatures. The insulation between wire and bobbin is of the order of one million megohms. In order to attain this high insulation, and at the same time to prevent the occurrence of polarisation effects, the wire should not be touched by hand while winding, but should be allowed to run through a clean cloth. The heating also eliminates the alteration of the specific resistance with time. In order to achieve this result most easily it is also important that

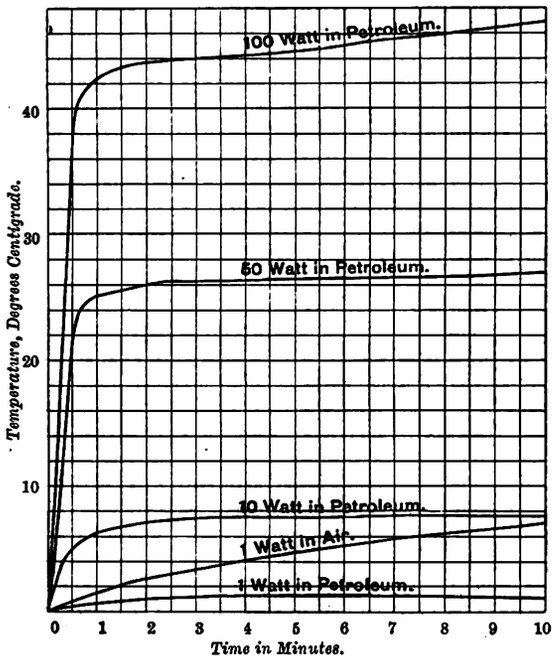

FIG. 2.

the wire should only be wound on cylinders having fairly large diameter. Obviously all unnecessary bending of the wire either before or during winding is to be avoided. It also appears advisable, for the same reason, that no very thick wire should be employed, but preferably that two or more wires in parallel should be used. Finally, an important consideration in the construction is that the apparatus should be so designed as to be capable of dissipating a large amount of electrical work in heat. The greater this is, the greater the range of use of the apparatus, and also the greater is the accuracy of the measurements.

The energy dissipated from the apparatus per second is expressed by the formula

$$Q = 0{\cdot}24\, J^2\omega \text{ cal} = (t_1 - t_2)\, F\, E,$$

where t_1 is the temperature of the wire, t_2 that of the surrounding medium, F the surface of the winding, and E the heat in calories dissipated per square centimetre surface per second per 1°C. difference of temperature. Our object is to secure a moderate heating of the wire for considerable values of Q. The surface F is therefore made as large as the dimensions of the whole apparatus will admit. We have a cylinder 4cm. diameter, with a wound length of about 4cm., making altogether about 100 sq. cm. radiating surface. It is therefore obvious why only one layer of wire is used; thus all parts of it are equally exposed to the surface, and can give off their heat. In order that the cooling of the surface should be great it is surrounded by an insulating mobile liquid. The best liquid for the purpose appears to be petroleum, since it is highly insulating, does not attack metal when pure, and leaves the shellac almost unaffected. Its large expansion with temperature ensures a good circulation from the coil round the whole bath. In order to assist this circulation, a fan is revolved in the bath, and a cooling worm can also be introduced to keep down the temperature.

A series of observations were made to determine the effect of these methods of cooling and to find a value for the quantity E under different conditions. The temperature of the wires was determined by a thermo-electric junction, while various currents were passed through the apparatus and the amount of cooling was varied. A standard resistance of 1 ohm, such as the one shown in Fig. 1, was immersed in a paraffin oil bath, 11cm. broad and 48cm. long, filled with liquid to a depth of 12cm., and provided with a fan fixed in the above manner. To one of the middle windings a copper wire and a constantan wire of 0·3mm. diameter were soldered. These wires rested on almost the same section main wire, were silk covered and enclosed in an ebonite *tube* of 1mm. diameter, which reached almost to the soldered joints, to prevent cooling. The copper wire was connected to a galvanometer, and from this a similar wire was joined to the end of the constantan wire coming from the coil. This second thermo-electric junction was immersed in a special petroleum both, the temperature of which was taken by a sensitive thermometer. Before each set of observations the galvanometer deflection given by a known difference of temperature between the two junctions was determined. Then various currents were passed through the coil so that 1, 10, 50 and 100 watts were dissipated by the instrument. The galvanometer deflections were observed every minute. The current in the resistances could be quickly reversed by a mercury commutator in order to eliminate the influence of the drop of potential in the main wire by observations with both directions of the current. In our apparatus the position of the thermo-electric couple was accidentally such that reversing the current produced no sensible effect.

The principal measurements* are shown in the curves (Fig. 2) and the corresponding Table I.

The curves show the variation of the temperature of the wire with time, for different expenditures of energy in the resistance. For large currents a constant temperature is reached in about 1min.; for smaller heating, and especially in air, a much greater time ($\frac{1}{2}$ to 1 hour) is required.

In Table I. W denotes the power expended, d the difference of temperature between the wire and liquid, and λ the calculated radiation per square centimetre per 1°C. temperature difference.

The resistance used in the investigations was constructed as shown in Fig. 1 (except that the diameter of the case was 70mm. instead of 85mm., as in the form shown), and was perforated in the same way with 5mm. holes in the bottom and sides. The fan in the bath was not rotated during the observations given above, as when moved the results were inconsistent. The increase of cooling when the fan *was* rotated was not great, sometimes even a decrease was observed. This is accounted for by the large coefficient of expansion of the paraffin oil, which causes hot streams of liquid to rise and escape by the holes in the cover, while the fan causes irregular currents. In any case, care must be taken that the current in the fan tube is directed downwards. But even then the cooling may be less rapid with the fan than without.

TABLE I.

W.	d.	λ
In air 1 watt	9·5°C.	0·00034
In paraffin 1 „	1·1°C.	0·0022
Do. 10 „	6·7°C.	0·0035
Do. 50 „	25·0°C.	0·0048
Do. 100 „	44·0°C.	0·0055

The casing of the apparatus is found to have considerable influence on the heating of the wire, since it opposes the motion of the air or liquid. Investigations were therefore made firstly without case, secondly with perforated, and thirdly with closed case. The following temperatures were observed:—

TABLE II.

—	Temperature in air after 30min.	Temperature in petroleum.	
	1 watt.	10 watts.	50 watts.
Without case	5·5°	6·5°	23·3°
With perforated case ...	9·5°	6·7°	25·0°
With closed case..... ...	12·7°	8·2°	32·8°

It is thus seen that the perforated case only alters the temperature of the wire by a small percentage, while a closed case causes a 30 to 40 per cent. greater rise in the temperature.

From column 3, Table I., it is seen that λ is not constant in petroleum (*i.e.*, the radiation from the surface is not proportional

* The investigation is given due to Herr Krannhals.

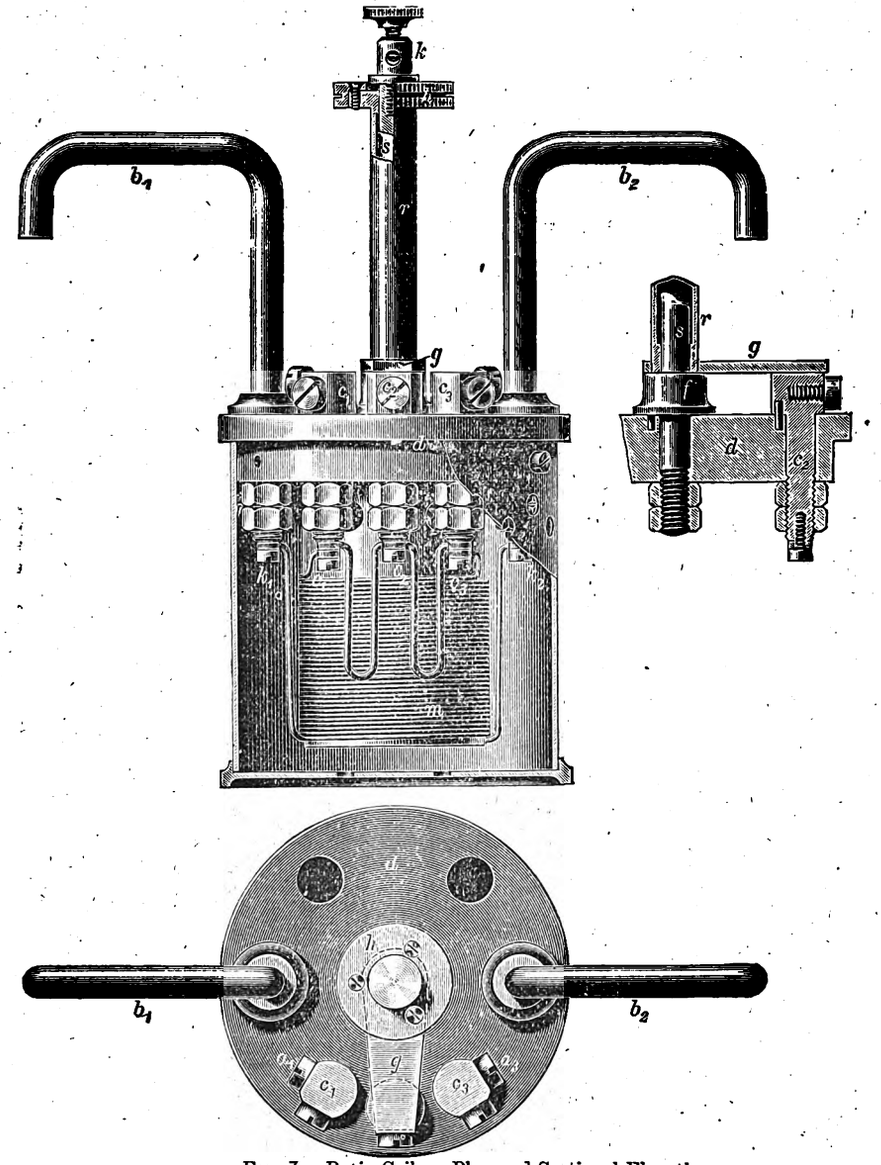

FIG. 3.—Ratio Coils. Plan and Sectional Elevation.

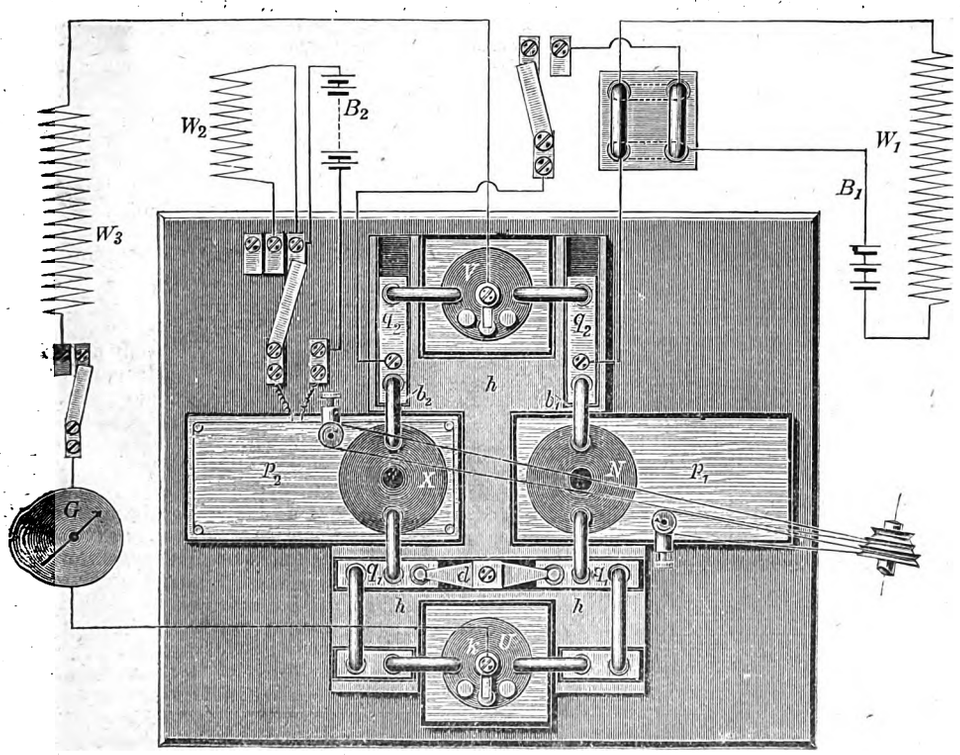

FIG. 4.—Apparatus for Standardising Resistances.

to the temperature difference *d*), and further, that the increase from 20°C. to 40°C. is greater than that from 0°C. to 20°C. This is easily accounted for by the greater mobility of paraffin at high temperatures.

The investigations described show that the standard paraffin bath resistances are capable of dissipating a large amount of heat. Originally these are wound with "patent nickel," and constructed for a maximum load of 1 watt. If the resistances are to be used as standards of precision, it is advisable, in order to make certain of their permanence with time, not to exceed this value, even with the new low-temperature coefficient alloys. For resistance comparisons there is usually no necessity to exceed this value. For *practical* measurements—for instance, the measurement of current by the potentiometer method—it is advisable to allow much greater energy dissipation. Resistances which should only be used for this purpose, and in which an accuracy of ½ per cent. is sufficient, can be loaded much more. From the above-mentioned measurements and the experience of the constancy of the resistance when maintained for a long time at a temperature of 100°C., as described in the original communication, it is found that for commercial standards of the above construction 100 watts may be allowed. Naturally care must be taken that the whole bath does not increase more than 10°C. in temperature. Either the current must only be passed for a short time (for the above size of bath containing about 4 litres, not more than 20min. with 100 watts), or powerful cooling of the paraffin must be adopted.

For measurements with the highest permissible current and high resistances the magnitude of the potential difference must be considered. It is advisable not to exceed 100 volts with this construction. We thus have the following values :—

TABLE III.

—	Highest permissible current.	
	Precision standards.	Commercial standards.
Ohms.	Amperes.	Amperes.
0·1	3·2	32·0
1·0	1.0	10·0
10·0	0·32	3·2
100·0	0·10	1·0
1,000·0	0·032	0·1
10,000·0	0·010	0·01

II.—PROCEDURE FOR THE COMPARISON OF STANDARD RESISTANCES.

The Thomson modification of the Wheatstone bridge which we have used for a number of years, with good results, for the accurate comparison of wire resistances with standards *of the same nominal value* will now be described.

(*a*) *Ratio Coils.*—Fig. 3 shows in plan and elevation the form of ratio coils used, which contain the two equal ratio resistances of the Wheatstone's bridge; between which resistances a small resistance is introduced for interpolation, which, for measurements of precision, is the thousandth part of each ratio resistance. For all practical cases two different classes of ratio coils are used, one with resistances of 100 ohms with an interpolation resistance of 0·1 ohm for the accurate comparison of higher resistances, from 0·1 ohm upwards; the other with ratios of 10 ohms and interpolation resistance of 0·01 ohm for the measurement of smaller

Digitized by Google

resistance down to 0·0001 ohm. A sliding contact connected to the galvanometer can be connected with three points of the interpolation resistance, viz., to the middle or to either end. It is thus in general not possible to bring the galvanometer deflection to zero as in a wire bridge; the relation of the resistances compared are interpolated from the deflections observed in the three possible positions of the contact.

As is shown in Fig. 3, the design of the ratio coil is in part the same as that of the wire standards (Fig. 1). The two ratio resistances are wound on the large brass tube m, and treated with the same care as the standard resistances, especially in the thorough ageing by heat. The outer end of each ratio resistance is soldered at k_1 and k_2 to the leading-in rods b_1 b_2, the inner ends to the contact blocks c_1 and c_3 fixed on the ebonite top. Between the contacts c_1 and c_3 the interpolation resistance (a wire or strip of 0·1 or 0·01 ohm) is soldered, the mid-point of which is connected with the contact c_2 in the same way. These contact blocks, c_1 c_2 c_3, are arranged on the ebonite top as shown in the figure, each about 1cm. diameter. In the middle of d a long thick rod, s, is fixed, which carries the terminal k for the reception of a galvanometer lead. Upon this rod a tube, r, loosely fits, to which below, where it slides upon a flange, f, the sliding contact g is brazed. Above, on the tube, is fixed a small ebonite-covered flange, upon which works a round nut separate from the terminal k. By turning the nut the pressure with which the sliding contact is made on the upper faces of c_1, c_2, or c_3 can be regulated. By turning the ebonite milled head h a sliding contact can be made on any one of the three blocks. Two stops on c_1 and c_3 prevent overturning. The rod s is made so long that the whole coil may be immersed in a petroleum bath, so that the contacts are about 1cm. under the surface of the liquid. The screws attached to the contact blocks, seen in the plan, which do not serve as stops, are used for measuring the single resistances. By these screws, also, high resistances may be connected in parallel with the ratio coils.

The comparison of the resistances with the given value can be performed with great accuracy; for example, for one of the Reichsanstalt ratio coils of manganin the following values were obtained:—

* *Ratio Resistances.*

Between k_1 c_1	100·013 ohms at	17·1deg.
,, k_2 c_3	100 012 ,,	17·3deg.

Interpolation Resistance.

Between c_1 c_2	0·0499 ohm at	17·5deg.
,, c_2 c_3	0·0498 ,,	17·5deg.

The minute inequalities in the resistances are eliminated by commuting—*i.e.*, by reversing the leads in their cups.

(*b*) *Wheatstone-Thomson Bridge for the Comparison of Standard Resistances.*—The use of the ratio coil requires no further explanation. The resistance to be measured, and a standard of the same nominal value, are connected together at one end, without any interposed resistance, by dipping their leads in the same mercury cup. From the mercury cups in which the other two leads dip, short thick copper wires are connected to the ends of the ratio coil, which completes the Wheatstone bridge. The leads to the galvanometer are connected to the terminal k of the ratio coil, and to the junction of the standard resistance and the resistance to be measured. The battery wires are connected in such a manner that the resistance of the thick, almost equally long, connections, when comparing resistances below 100 or 10 ohms, are added to the resistances of the ratio coil of 100 or 10 ohms, and thus, even in the most accurate measurements, may be neglected. In this simple method of connection, the ratio coil can be conveniently used for the calibration of rheostats, and for the comparison of one coil with a standard. For the rapid testing of resistance boxes, potentiometers, &c., this simple and convenient method is always used in the Reichsanstalt.

As has been seen above, screws are provided in order to allow high resistances to be connected in parallel, and thus to obtain known ratios. Thus it is possible, by shunting a 100-ohm ratio coil with 35,000 ohms, to alter the ratio of the two resistances, reckoned from c_2 in the ratio of 106·0/106·3; thus resistances which are adjusted in *legal* ohms may be compared with those based on the new *international* ohm without getting too great deflections when the contact g is on the block c_2. The shunt connection is so arranged that a small inequality in the ratio coils can be eliminated by commuting. In many cases, however, the resistance to be measured and the standard cannot be arranged with an end of each in the same mercury cup—for example, when the unknown resistance is to be tested at different temperatures, or if, as in the case of standard resistances of low value,* the resistance of a coil is not reckoned from the *outer* ends of the leads. In this case the bridge can be easily transformed as in Thomson's method.

In Fig. 4 is shown the arrangement for standards of the Reichsanstalt model, but which is easily adapted to allow wire resistances of any magnitude and also plate resistances of 0·01 or 0·001 ohm (the so-called small pattern) to be compared with standards of the same nominal value, and their temperature coefficient tested. The standard N and the resistance X to be measured are immersed in *separate* petroleum baths as before described.* In p_2 a rectangular frame of perforated brass sheet is immersed which carries an insulated winding of resistance wire wound from the bottom to the top of the liquid. This serves for the heating of the bath by current, for testing temperature coefficients. The required current is provided by the secondary battery B_2, which is also used for the galvanometer lamp and for driving a small electromotor. By means of a rheostat W_2, in the base of the apparatus, a uniform temperature is attained in p_2 in a short time. If, on the contrary, a lower temperature is required a cooling worm is inserted in p_2, through which cold water is passed. The petroleum in both baths is kept in constant motion by two small pumps driven by an electromotor. The two resistances N and X are on one side connected by a thick copper plate, d, which makes contact with its amalgamated ends in small cups in the mercury cup blocks q_1 q_1, and carries a terminal in the middle. Since the resistance of this connector is very small the galvanometer is connected directly to the terminal d when comparing high resistances at the temperature of the room. If the baths p_1 and p_2 are at very different temperatures, a 10-ohm ratio coil U in a small petroleum bath is connected up, bridging over d, and the galvanometer connection is made to the terminal k on the coil U. The influence of thermo-electric forces is thereby greatly diminished, and the resistance of the connector itself, when N and X are 0·001 ohm or less, is eliminated, as in Thomson's modification of Wheatstone's bridge. The leads b_1 and b_2 of N and X rest in long mercury cup blocks, q_2 q_2, between which a ratio coil, V (for comparison of resistances of 0·1 ohm upwards, usually a 100-ohm, and for lower resistances a 10-ohm coil) is connected in the same way, which is also immersed in a separate petroleum bath. In the battery circuit are one or more secondary cells, B_1, a commutator, switch, and regulating resistance, W_1; a similar resistance, W_3, is inserted in the galvanometer circuit.

The whole of the measuring apparatus is immersed in petroleum, the temperature of which in p_1 and p_2 can be measured by thermometers inserted in the coils. In this manner not only the temperature of the resistances can be accurately known, but the thermo-electric forces (a source of error which need scarcely be considered when using manganin) are almost eliminated. It should be mentioned that the wooden supports for the mercury cups are not solid, but are hollowed and filled with kieselguhr.

In practice, with the above arrangement, resistances can be quickly and accurately compared to a few millionths of their value. The accuracy attained in the measurement will be illustrated by an example.†

III.—Constancy of the Wire Resistances.

In order to discover the behaviour of the type of standard resistance described in Section I., in practical use, 45 of these coils, which were tested in the Reichsanstalt in the years 1891 and 1892, were on the request of the Reichsanstalt returned by the owners and underwent a further test in June, 1894. These resistances were mostly graduated in tenths and were for the most part used in electrotechnical and physical laboratories and some of them in electrotechnical workshops and central stations. The measurements were conducted as described above, the resistances being always compared with standards of the same kind, the constancy of which had been periodically compared, directly or indirectly, with the mercury standard. The results of these measurements, published in the *Wissenschaftlichen Abhandlung*, were the following: Of all 45 wire resistances tested (42 of manganin, 3 of constantan) we have for a period of from 1½ to 3 years—

25	coils showed a variation of from		0·00	to 0·01	per cent.
13	,,	,,	,,	0·01 ,, 0·02	,,
5	,,	,,	,,	0·02 ,, 0·05	,,
2	,,	,,	,,	5·05 ,, 0·25	,,

It must be remarked that these resistances were not only used in laboratories for resistance measurements with small currents, but also for the measurement of currents by indirect comparison, so that in some cases the current density certainly exceeded the permissible values for measurements of precision. From these results the conclusion has been arrived at that *manganin has been found very suitable for wire resistances in practical use.*

Of standards wound with constantan too few have been tested to be able to pronounce definitely upon their constancy; still, it would appear from experience up to the present that constantan is equally good in this respect. The properties of constantan render it especially suitable for rough technical resistances in which less accuracy is required than for resistances of precision. The experience with these resistances will be made public later.

The above-mentioned periodic comparisons of the primary wire-standard of the Reichsanstalt, with accurately-determined mercury

* Feussner. *Zeitschrift für Instrumentenkunde*, 10, S. 425, 1890.

† A lengthy example is given here in the original text.—Ed. *E.*

Digitized by Google

resistances, give very satisfactory results as to the constancy of the resistance, and give also valuable proof of the degree of constancy of the resistance value, which may now-a-days be reached with properly made wire standards. For the first series of these comparisons the *primitive* mercury standard of the Reichsanstalt, which is described in the *Zeitschrift für Instrumentenkunde*, 11, S. 173, 1891, was used. Later the wire resistance was connected to the *ultimate* (*definitiv*)* mercury standard (*see* W. Jaeger, *Wissenschaftlichen Abhandlungen der P. T. R.*, 2, S. 1) in October, 1892, November, 1893, and May, 1894. It appears that for 7 one-ohm wire standards (5 manganin, 2 "patentnickel") the greatest resistance variation was 0 004 per cent., so that already it appears difficult to guarantee the constancy of the fundamental unit of comparison over the whole period.

ELECTRIC ELEVATORS, WITH DETAILED DESCRIPTION OF SPECIAL TYPES.†

BY FRANK J. SPRAGUE.

The time has passed when anyone can doubt that one of the most important applications of the electric transmission of power and one in the number and variety of its applications already rivalling the electric railway work which has made such marvellous strides in the past eight years, is that of the operation of all classes of hoisting machinery. Some idea of the extent of the present elevator business may be gathered from the fact that in New York City alone there are not less than 5,000 elevators of various kinds, more, in fact, than there are street cars, and more people are carried vertically than there are horizontally. Ignoring for the moment the specific methods of application, and discounting the difficulties naturally met in developing machines to do the duty required in modern office work, not alone the technical difficulties, but those commercial ones naturally met when a new company enters the lists with untried machines against the entrenched forces of existing industries, there was still much of encouragement to be derived from a backward glance at the industrial changes wrought in the last few years. The elevator field, indeed, is a large one, and if the system is electric, then, considered from a commercial standpoint, there appears the following possible classes of work :—

1. High-speed passenger service where no hydraulic plant is possible because of limited space.

2. High-speed passenger service in competition with hydraulic plants, the electric plant doing equal duty, costing less, occupying less space than the hydraulic, and costing much less to operate.

3. Substitution of new high-speed electric service in place of old steam and slow hydraulic services in buildings where the limited space and interference with operations will not permit consideration of a new hydraulic plant.

4. Passenger elevator service in buildings where the loads are comparatively light.

5. Passenger service in private houses where safety, simplicity and noiselessness are essential.

6. Freight and special classes of work.

For convenience we may classify elevator work as "first-class, that requiring speeds from 300ft. to 600ft. a minute," including the first three duties above mentioned, and as "second class" those requiring speeds of from 50ft. to 250ft. a minute," which include the remainder. In general there has been required and developed two kinds of machines to perform these services. The first is the outcome of the increased height of buildings and the demand for high speed and smooth motion, largely regardless of cost of apparatus, space occupied, or cost of operation. The hydraulic elevator was the result of this demand, and was the only one that up to a year or so ago was accepted for this service.

The second class of elevator work, that which requires lower speeds, is applied to small apartment houses and other buildings where lighter elevator duty is required. This, for a long time, has been fairly supplied by worm-gear elevators, and the replacing of the steam engine by an electric motor has enormously broadened the field for this class of machine.

Taking the drum type, and considering electrical control on a machine over-balanced for average service, the load up or down is sometimes with and sometimes against the machine. To control such a machine directly from a supply circuit (and I cannot seriously consider any other, no matter how ingenious or refined, as meeting general conditions), there is one method only, and that is the use of a rheostat in starting, and the inverse variation of the strength of the shunt field for about a two to one variation in speed. A cumulative series coil is only permissible in starting if variations of speeds are controllable, and in any event these variations are limited. Such a machine is, however, the best for second-class service.

Let us consider for a moment a hydraulic system, and institute a few comparisons. It consists primarily of a steam cylinder, or a multiplicity of steam cylinders, working ordinarily under poor conditions of steam economy—that is, with a fixed cut-out in the high-pressure cylinder of a compound pump, or no cut-off in any cylinder of a simple pump. This element corresponds to the cylinders of a steam engine in the electric system, which use steam expansively with a cut-off varying according to the load, and under pressure conditions which are somewhat better than exist in a pump. It is to duplicate the results of this system of variable cut-offs and steam expansion, that the energies of the various pump builders have been more or less ineffectually bent for a great many years in plain acknowledgment of that defect in their simple and duplex pumps, the latter of which is common to almost every hydraulic plant of any size in the United States. It is true that a so-called "high duty" pump with equalising piston is used on some of the larger elevator plants, but its use has not proven by any means entirely successful, because of the spasmodic nature of the service. Among the high duty pumps, the flywheel type, such as is used on large water pumping stations, has been attempted, but rarely, I may fairly say, with success.

The next element is the water cylinder, which corresponds to the dynamo in the electric system, and on account of the high friction due to the packing, the efficiency of a water cylinder with its valves is not ordinarily equal to that of a dynamo, which with a motor stands to-day the typical example of an efficient energy converter. The next element is the piping and the tanks, compression or roof, and perhaps an accumulator, into or through which the water is pumped for delivery to the controlling valves of the elevator, and that which corresponds to this in the electric system is its simple wiring, and if a storage battery is used, then this last in conjunction with it.

Any competent engineer knows that, measured by standard practice, a given number of pounds of energy can be delivered to the controlling apparatus of an electric elevator for less pounds of steam—that is, water evaporated—through the medium of no less than 50 combinations of engines and dynamos, than can be delivered to the valves of any hydraulic cylinder through the standard pumps permissible in average elevator service. To be specific, the average water evaporation on a compound duplex pump, which is almost universally used, will in practice be not less than about 60lb. to 70lb. per horse-power of water energy delivered to the controlling valves, whereas the electric combination will easily give the same for less than 40lb.

There are exceptional conditions in which a higher economy can be gotten in a hydraulic system, but they are few and are not typical, and under equal conditions the steam consumption in an electric system can be cut in two.

But this is not all. The fact is persistently ignored, although the attempt is made to offset it by recent experiments with a differential piston, that a standard hydraulic elevator uses the same amount of water under the same pressure for every foot of travel of a car, which volume of water and pressure are determined by the maximum load which has to be carried, although the average load on the ropes, including the excess of car over counterweight, is not over one-third of the maximum. On the other hand, the electric elevator uses, and must use, under normal conditions, current directly proportional to the work, modified in a small degree by starting and slow running. In short, over and above the friction load of the generating system, the steam consumption in the engines and the generation of electricity in the dynamo vary with the demand of the elevator machines. It is a system which is of necessity automatic. On the other hand, the hydraulic system is one of the most flagrant violators of the relation which should exist between demand and supply.

Leaving out central station supply—always, when properly equipped, to be preferred when the electric service is of a spasmodic or limited character—and considering for the present those large plants which characterise the modern office or hotel building

* This *ultimate* standard agrees with the *primitive* to 0·0001. For the production of wire copies of the latter the value of Mascart, Nerville and Benoît for the specific resistance of mercury at the observing temperature of 18deg. (σ_{18}=1·01608) was used. This latter value is, with great probability, from the measurements of Herren Kreichgauer and Jaeger (*Wied. Ann.*, 47, S. 513, 1892) on the one hand, and of Guillaume on the other, about 0·0022 too small. The absolute accuracy of 0·0001, which, up to October, 1892, was given for the Reichsanstalt standard of 1 ohm, is thus on this account also somewhat too great. For all wire standards tested after October, 1892, in *legal* ohms, the absolute accuracy can be only taken as 0·0003. By multiplication by 1·0002 the error due to the mistaken temperature coefficient of mercury can be eliminated, and thus the absolute accuracy of all these resistances would be well within 0·0001. For the resistances standardised by the international ohm the ultimate mercury standard is used as a basis (measured at 0°C.), which is not affected by any inaccuracy in the temperature coefficient of mercury. Thus the standard coils of 1 ohm may be relied on to an accuracy of 0·0001.

† Abstract of a Paper read before the American Institute of Electrical Engineers

Digitized by Google

and in a way rival central stations, every engineer knows that the fewer the number of well-proportioned units the more alike they are, the freer the interchangeability between themselves, and the greater the extent to which any one unit can be utilised, the better the system for power generation and conversion, no matter what its character.

The best modern practice makes a three-unit direct-connected engine and dynamo plant the best for lighting a building. There is an empirical relation existing between the number of lights required in a building as ordinarily designed, and the elevator service. When, in addition to the lighting service, such a building adopts electric elevators, it is not now necessary that it shall add an independent generating plant.

All that is required is that the three units should be somewhat increased in size and, perhaps, one of them preferably divided, the mains all taken to a common switchboard with two-way switches, and every engine and dynamo thus made interchangeable on either the lighting or elevator circuits, and at times both, especially if using a slow-acting corrective converter, some of each can be run from the same engine anp dynamo. So, instead of five or six units, some water and some electric, the entire generating plant is reduced to a single system consisting of three units of one size, or two of that size and two of a half size, which can be run interchangeably, and one of which is almost always in reserve.

Just here it is well to consider the probable application of the storage battery, which, if built with plenty of lead, with large surfaces and for heavy momentary discharges rather than for long-time steady discharges, will prove a most important adjunct to elevator service, which, like railway work, is spasmodic in character.

To meet the hydraulic machine there was designed and developed what is now known as the Sprague-Pratt multiple sheave electric screw elevator, following the general lines of a tension hydraulic machine in the matter of rope movement, limit safeties, and method of control. The net result has been that this machine now stands the superior to the hydraulic elevator in that it has its speed and capacity with, if anything, greater safety, and certain advantages in its automatics. On high lifts it occupies less space, it is more flexible in its application, is more economical to operate, and it is more easily cared for.

General Description.—The machine may be described as the combination of two old elements with one new one, with specific safeties and methods of control. Briefly, it is of the horizontal multiple sheave type, with a travelling crosshead and frictionless nut driven by a screw revolved by a motor directly connected, and governed by a pilot motor and rheostat. The general construction consists of a heavy main beam, carrying the travelling crosshead and the lower screw bearing, with special castings bolted at each end, one carrying the fixed set of sheaves, and the other the thrust bearing, brake and motor. The regulating apparatus is independent and self-contained, and placed on the wall. From the car to the system of multiplying sheaves the direct multiplying machine and the horizontal hydraulic elevator are practically the same. The crosshead, however, marks the point of departure in the two types. In the hydraulic machine, this crosshead is rigidly attached to the end of a rod which terminates in a piston moving in a cylinder having an inside length equal to the lineal movement of the crosshead. This cylinder in the vertical type of hydraulics varies from 30ft. to 50ft. in length, with from 2 to 12 sheave multiplications, and in the horizontal types the multiplication runs as high as 14, with corresponding diminution of length of cylinder and increase in cross-section. Whatever the gearing, however, the length of cylinder is a function of the car travel. In this electric elevator, the crosshead being moved along a screw, stationary so far as the lineal movement is concerned, there is, with any given number of sheaves—only one variable—the length of screw; and, for all heights above about 100ft., the electric machine has an advantage in matter of length, which, with increased rises, becomes of great importance.

Looking to the needs of office buildings, there has been adopted two methods of rope multiplication, determined by the height of building, and so selected that the length of machine over all shall not exceed about 30ft. for rises approaching 300ft. actual car travel. From this the length grades down to about 21ft., so that all rises between 60ft. and 300ft. can be taken care of with an extreme variation of 9ft. or 10ft. in the length of machine, and there is thus provided limiting dimension data of great convenience and utility.

These systems of multiplication I may term direct and indirect. In the former, the entire multiplication, varying from six to ten, is done at the machine, and the ropes lead from the end sheaves over the shaft sheaves direct to the car. A free counter-weight is used, the ropes being fastened to the car frame.

Economy of operation and smoothness of movement, however, are antagonistic in their relations to the amount of counter-weight carried. The best method is probably that used when there is a single multiplication in the shaft, giving a two to one counter-weight travelling at half-speed, and carried by all the car-hoisting ropes, as is done for short-rise vertical hydraulic elevators.

For long rises I have adopted a combination vertical and horizontal machine rope practice, giving even a more compact machine, a longer life of ropes, and better counter-weight results.

Where space is limited I use a double-decked machine, and in the new Commercial Cable Building, which is to be 21 stories high, the machines will be treble decked, and about 10½ft. in height.

Details.—Turning now to the detail construction and operation of this machine, there are a number of features claiming special attention, each unique in character, and marking a radical departure from all other elevator practice. These are the nut, screw and thrust bearing, the brake, the motor and the regulator apparatus. One of the most interesting as well as important features, and, perhaps, the one which has been most frequently attacked, is the nut system. It joins the crosshead of the travelling sheaves by a conical seat. There is no fastening between the nut and the crosshead, the continual weight of the car always keeping them in contact; and the friction at this point, being greater than between the nut and the screw, enables the latter to transmit a straight-line movement in the crosshead when the screw is revolved by the motor, and also to revolve the screw and drive the motor as a dynamo when the mechanical brake releases the screw to allow the car to descend. These are the normal functions of hoisting and lowering. There are several other distinct functions of this nut which will be described in considering the "safeties."

Continuing the line of transmission of power, the only points of contact between the interlocking nut and screw are by a chain of balls which occupy a number of threads, and enter and leave the ends of the nut through tubes which are connected together so as to make a continuous conduit. This is one of the most vital points of the elevator apparatus, and herein lies one of the most potent reasons of its success—the reduction of friction by rolling instead of sliding surfaces on almost all parts under pressure—for not only is the nut so constituted, being in fact a developed spiral thrust bearing, but the thrust bearing at the motor end of the screw is taken on balls, and the sheaves are carried on ball or roller bearings.

This nut being a vital part, its development has been most thorough, and a peculiar treatment of steel which has been adopted renders its surface so hard that the wear is very small, and it is well within commercial limits.

So free is the machine from static friction that it is possible to start the car with a very slight increase of current over the normal hoisting current, providing time be taken so that the work done in acceleration is small to the work of lifting, although that is not the usual practice. The balls have an average crushing strain of 25,000lb. each, but the working pressure varies from only 50lb. to 125lb. per ball. The nut system is a compound one, for, besides the working-ball nut, there is another, called the "safety nut," to which I will make reference later, keyed to it, and between the two is a powerful spring under compression. The screw is a forged bar of high carbon steel, with a peculiarly-shaped thread, the finished screw having a tensile strength of 700,000lb. It passes through the clearance hole in the steel trunnion crosshead, which carries the travelling sheaves, then through the nut, and is carried at the outer end by a fixed bearing. This screw is sectioned, being joined to the armature shaft by a cone-seated coupling secured by a taper gib.

The in-board end of the armature shaft, which is in effect the extension of the screw, terminates in the thrust bearing, where the pressure is taken by about 200 steel balls carried in a bronze guide plate and bearing by specially-hardened steel discs. The thrust of the screw being thus taken up on the in-board end, the strain on the screw is invariably between that end and the travelling crosshead—never beyond this; hence it is always under extension strain—never under compression, and cannot buckle.

The action of the balls on the screw, which is untreated, is peculiar. They form a path for themselves, partly by wear, but principally by rolling compression of the steel, which finally becomes exceedingly hard, such that the edge of any ordinary machine tool would be turned. The balls themselves wear very evenly. Oblique forms in normal practice cannot exist. Beyond the thrust plates is keyed an iron pulley, connected by a flexible coupling with the motor shaft. The function of the brake is that of locking the screw when at rest; it is not a means of varying the speed. In case of accident it has the additional function of helping to stop the screw. It may be described as a compound electro-mechanical brake. A steel brake band, wood-lined, is anchored at one end, the hoisting-side on the motor-bed frame, and the other end is continually pulled down by a powerful spring under compression. The mechanical movement in opposition is through the medium of a peculiar magnet. It is operated by a dual circuit, one in hoisting, another in lowering. In the event of failure of current for any reason, or too high a speed on the down run, this magnet releases the brake in the latter case by a snap switch, operated by an adjustable Pickering centrifugal governor driven by the main screw—and the brake band promptly grips the brake wheel softly yet powerfully.

Digitized by Google

Motor.—The motor, which is of the multipolar type, is carried on the same casting which contains the thrust bearing. The field magnets are of steel, and are excited by two circuits; one, known as the shunt circuit, being variable in strength at will, so as to vary the maximum speed of the machine, and the other, a series circuit, which acts to strongly compound the field. This type of elevators is differentiated from all other electrics by the fact that the action is like that of the hydraulic, for it always works against gravity. In hoisting, the motor takes current from the line, but in lowering its main circuit is cut off from the line, and the motor, rotating in an opposite direction, is driven as a dynamo by the weight of the car. A strong element of safety existed in the fact that the current in the field coils is never reversed, and consequently the machine is never demagnetised. Hence, under certain conditions of the operation of the safeties, it has a power of self-excitation which is of importance. The armature which turns in this field is of the ironclad type, and not liable to injury of any kind. It is mounted on a sleeve, is of the 2-path series winding, has a very large commutator, and, of course, multiple carbon brushes. The field coils can be removed without disturbing any other part.

Control.—Considered in its simplest form, and in connection with its action upon the motor and multiplying machine, without reference to the means of communication between the car and the regulator, this last is a very simple device. It is composed of two parts, each made up of peculiarly-shaped iron grids of various sizes arranged in circular form, connected to copper contacts on a slate disc over which passes a heavy carbon brush. The use of iron castings of a specific composition possesses great advantage over any form of wire resistance, not alone in the matter of cost. They are flexible, they expand in any direction readily, and, as made, they have a resistance of from forty to fifty times that of copper, or roughly, that of German silver. The grids are interchangeable, and any of them can be readily replaced.

One side of the rheostat is for regulation in hoisting, the other for lowering. Instead of moving this regulator by hand it is operated by a pilot motor wound with a right and left-handed field, one or the other of which only at a time can be in circuit with the armature. This pilot is connected to the rheostat arm by a single-reduction worm gear, and is operated either from the basement or the car, according to the position of the "change over" switch, by an "up" and "down" button with an automatic lever stop which normally has to be held by the operator to prevent the pilot returning to a stop position. The spindle of the rheostat arm operates switches co-ordinating in their movement, in turn controlling the magnetic make-and-break circuit switches, the down brake, and also the automatic stop lever switches which limit the pilot movement. The use of magnetic switches instead of hand-control switches not only removes the arcing from the face of the rheostat, but it gives the benefit of instantaneous cut-offs not possible by any other means of control. This, on fast machines, is of the utmost importance, and the practical application is that if a car is on the "up motion," and an operator, because of carelessness or because of fright, lets go his stop handle, the current is instantly cut off, the regulator following to stop, and the car is arrested in the shortest time practicable.

Assuming that the circuit is made for the up movement, it first meets with a resistance sufficient to about hold the car and lift the brake. This resistance is then gradually cut out, the torsional effort of the armature is increased, giving the car an upward movement with an acceleration depending upon the rate of movement of the rheostat arm, and with a final velocity determined by the point at which the arm is stopped. If, while hoisting, for any reason the current is cut off, the torsional effort ceases, the brake instantly comes into action, and the car comes to rest.

In lowering, the brake is lifted by an independent circuit, but the armature is first short-circuited on itself, and becomes a most powerful dynamic brake. As the resistance in this circuit is increased, the car runs faster. When it approaches the lower limit of movement, an independent retarding circuit is established, and gradually reduces the resistance. This brings the car to the slowest movement.

The pilot movement regulation is, to my mind, an absolute necessity of fast passenger work; and its application, although at first attended with a number of annoying difficulties, is to-day by far the most reliable method of control known.

Safeties.—On the car we use a special centrifugal which is attached to the lower section of the car frame. It consists of two long levers, short-fulcrumed at the sides of the car and operating clamping jaws which run in close proximity to the car rails, but normally out of contact with them. On the hoisting machine there are a number of safeties. One which is perfectly apparent is due to the fact that the crosshead is moved by a screw with a heavy armature on the end of it, which is driven through the medium of a nut by a car of limited driving capacity. The screw itself is of forged steel, under tension and torsion strains, with a safety factor of at least 20 to 1.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-day) FRIDAY, February 14th.

KINGS COLLEGE ENGINEERING SOCIETY.

4:15 p.m. Meeting at King's College, Strand. Paper to be read: "The Time Rate of the Growth of Magnetism in Iron, and its Importance to the Electrical Engineer, with experiments," by Ernest Wilson.

PHYSICAL SOCIETY.

5 p.m. Annual General Meeting at Burlington House. Paper to be read: "On the Determination of High Temperatures with the Meldometer," by Prof. W. Ramsay and N. Eumorfopoulos.

MONDAY, February 17th.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture I.: "The Chemistry of Certain Metals and their Compounds used in Building, and the Changes produced in them by Air, Moisture, and Noxious Gases, &c.," by Prof. J. M. Thomson.

TUESDAY, February 18th.

SOCIETY OF ARTS.

8 p.m. Foreign and Colonial Section. Paper to be read: "The Development of Electrical Traction Apparatus," by H. F. Parshall.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be further discussed: "The Manufacture of Aluminium by Electrolysis, and the Plant at Niagara for its Extraction," by Alfred E. Hunt.

WEDNESDAY, February 19th.

ROYAL METEOROLOGICAL SOCIETY.

7:30 p.m. Ordinary Meeting at the Institution of Civil Engineers, 25, Great George-street, Westminster.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Paper to be read: "Report of the Royal Commission on Secondary Education," by H. Macan.

THURSDAY, February 20th.

FINSBURY TECHNICAL COLLEGE.

Biennial Conversazione.

FRIDAY, February 21st.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Students' Meeting. Paper to be read: "Some Central Station Experience," by W. Fennell.

SATURDAY, February 22nd.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "Light," by the Right Hon Lord Rayleigh.

BOOKS RECEIVED.

"Computation Rules and Logarithms." By Silas W. Holman. (New York: Macmillan and Co.) Price 5s.

"Laxton's Price Book" for 1896. 79th Edition. (London: Kelly and Co.) Price 4s.

"Chemistry for Engineers and Manufacturers." By Bertram Blount and A. G. Bloxam. Vol. 1. (London: Charles Griffin & Co.)

"The Engineer's Year Book" for 1896. By H. R. Kempe. (London: Crosby, Lockwood and Son.) Price, 8s.

"Flicker" Photometry of Coloured Lights.—In the current number of the *Physical Review* of New York Mr. F. P. Whitman gives some account of the use of the "flicker" photometer in comparing lights of different colour, and states that this method approximates in convenience and accuracy to any of the ordinary photometric appliances using lights of the same colour. The chief test by which this conclusion is arrived at is that different observers whose vision is normal obtain similar results; whereas, by other methods, the comparison of coloured lights by different observers was found to give results often differing by 50 per cent. The flicker method of photometry is based upon researches made by Prof. Rood, who has shown that if a rotating disc, rotating rather slowly, is painted with two different shades, either of gray or some other colour, a flicker is produced, which, however, will gradually disappear if successive pairs of colours more and more alike are chosen. The author has adapted this principle to a photometer, which he calls a flicker photometer, in which a rotating sector disc is made to give intermittent comparisons between two coloured lights on a photometer bar. It is found that differences in colour do not, with such an instrument, affect the measurements.

The Electrician.

The Oldest Electrical Journal (1861—1878.)

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny
Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone No. 6949. *Telegrams:* "ELECTRICIAN NEWSPAPER LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed "Coutts and Co."*

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The Rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	Year.	Half-Year.	Quarter.
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.

(Post free, payable in advance.)

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 4 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. FLEMING, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Vol. I. Price 12s. 6d., post free 13s. *Vol. II. is in preparation.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.

VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free, 8s.

VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. 93 original illustrations, handsomely bound. price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. SNELL. 10s. 6d.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free 8s.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GHIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d. net, post free, 13s., abroad, 13s. 6d.

"THE ELECTRICIAN" PRIMERS. In Two Volumes. Price: Stout paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

THE WORK OF HERTZ. By Dr. O. J. LODGE. Price 2s. 6d.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c. By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. *[In preparation.*

MOTIVE POWER AND GEARING. By E. TREMLETT CARTER. *[In preparation.*

FULL CATALOGUE POST FREE ON APPLICATION.

NOW READY.—Vol. XXXV. of "THE ELECTRICIAN," bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

The published price of Volumes previous to Vol. XXXV. is 12s. 6d. post free 13s. 6d. Many of these Volumes are very scarce.

GERMAN STANDARDS.

In the lucid intervals—which have of late been very few and very far between—when the British taxpayer is permitted to withdraw his attention from Boer politics and the vagaries of South American Republics, and to give some little consideration to the affairs of his own dull domestic circle, there is one perennial question—Education—which is always to the front. The cry which is ever heard above the discordant strife of formularies, codes, schemes secondary, schemes technical, and the like, is "More Money." No one cares to spend money for "that which is naught," but most reasonable men are willing and ready to give of their substance, provided they can realise that something is produced, some good attained for themselves or others—especially the former.

We print on another page a Paper by Drs. FEUSSNER and LINDECK, which throws light on an aspect of the education question that has not, so far, been brought very prominently before the tax-paying public. To the initiated, however, the function of research as a part of the education problem, both in its relation to that increase of knowlege which concerns itself with teaching "the young idea," and in relation to that other increase which has for its object the general improvement of industrial processes and methods, is becoming every day more fully appreciated. This growing need has so far been met in this country by individual effort, with the consequence that an unknown, but certainly very large, amount of money and skill has been frittered away in needlessly repeating investigations that might have been carried out once and for all. It is true that we can point to good research work carried out by associations, institutions and societies for the common weal, though such work has been none too plentiful. But small as it has been, it has served to show how important such work is to our national industry, and how much need there is for a greater and greater development along these or similar lines. What the proper lines are is a matter which urgently calls for discussion. As an instance

Digitized by Google

of the way in which the Germans have sought to solve the problem, we may cite the splendid fruit yielded by their national laboratory at Charlottenburg, not, be it remembered, in the high altitudes of pure research, but in the prosaic production and testing of apparatus of precision and appliances for the measurement and comparison of resistances. Assuming that our British instrument makers are on a level with those of other countries, both for precision of work and accuracy of method, it must nevertheless be acknowledged that the attainment of their high standard of excellence has been the result of an unduly lavish outlay. The English method, moreover, tends to a cast-iron inflexibility of design. Is it conceivable, for instance, that the material and form of our resistance standards would have been perpetuated for 30 years if there had been in existence a public institution charged, amongst other duties, with the investigation of the production and preservation of standards of electric resistance? The Cavendish Laboratory has been the scene of excellent scientific work of all kinds, and notably in the matter of testing electric resistances, but neither a MAXWELL nor a RAYLEIGH, with all their experimental genius, can make bricks without straw or costly researches without funds. Notwithstanding the exceeding excellence of their intentions, the British Association, since MATTHIESSEN'S work of 32 years ago, has only been able to provide its Electrical Units Committee with an extremely modest endowment. MATTHIESSEN'S work ought to have been followed up as new manufacturing processes were introduced, and reliable alloys with valuable properties were gradually evolved. That duty, however, remained unfulfilled for over a quarter of a century, until the establishment of the Reichsanstalt created the opportunity which was eagerly seized by HELMHOLTZ and his staff, and the vigour and skill with which the duty has been performed are attested by the invention of "constantan" and "manganin."

In a future issue we hope to refer more in detail to the forms of apparatus and methods described by Drs. FEUSSNER and LINDECK, and to the results quoted by them. Meanwhile, we commend the Paper to the careful consideration of educationalists and manufacturers, so that they may see how useful such an institution as the Reichsanstalt may be to *them*, not merely, we repeat once more, to the high-and-dry professor. That some such State-endowed laboratory or laboratories should be founded in this country is already abundantly evident, and the spheres of influence in which they can fittingly operate are widening every day. It is all very well to ruthlessly cry "*delenda est Germania*." Even if this feat were possible no permanent good can accrue unless we learn the lesson that German industrial rivalry repeats *ad nauseam* —to wit, the supreme necessity of adopting scientific methods throughout, from the raising of the raw product to its final transference, in return for hard cash, into the hand of the consumer. A servile imitation of German methods is neither desirable nor in all probability feasible, since the racial factor is a stubborn one, which cannot be neglected; what may suit the Teutonic temperament is scarcely likely to suit equally well the free and easy Briton. Science, to use an Americanism, has come to stay; the sooner we Britons pay a more fitting tribute to it the sooner shall we be able to dispense with the adventitious aids advocated by the economic crank. Just at present all the energy, enterprise and originality so long characteristic of the race would seem to be concentrated on the confines of the Empire, whilst those at home are lazily content to rely on big battleships and other such implements of war to "smash, pulverise and destroy" their trade rivals.

BRIGHTON CURVES.

Everyone who has had the privilege of visiting the very successful municipal electric lighting station at Brighton, under the kindly *ægis* of Mr. Arthur Wright, must have come away with the conviction that if elaborate statistic spinning and unwearied curve-tracing can ensure economical working, there is no need to go further in pursuit of the cause of the pronounced prosperity of the Brighton municipal venture. However, the now popular "Wright" method of charging for current, and the ingenious combination of low-pressure continuous-current and high-pressure alternate-current supply in one and the same outlying district, are evidences that something else than accurate measurement of outgoings and incomings has contributed to the prominent position now held by Brighton in the long list of municipal electrical undertakings. But statistics have the merit of being capable of reduction to the form of curves, and two curves from Mr. Wright's museum, which we give this week, will, we venture to think, preach to central station engineers the gospel of Brighton better than any long disquisition or wearisome analysis.

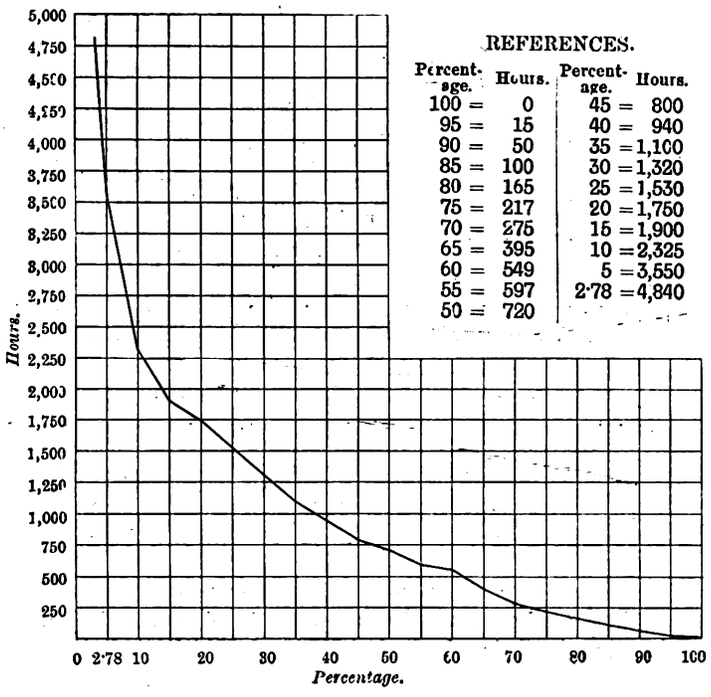

FIG. 2.—Curve showing number of hours the Load on the Brighton Station exceeded a given percentage of the annual maximum load.

The curve (Fig. 1), which has been brought up to December, 1895, shows how much more nearly the total expenditure of a municipal central station varies in accordance with the maximum rate at which this is called upon to deliver in each year, than it does on the total number of units sold in any month during that year. For instance, the solid line shows the actual sale of electricity in every month since January, 1892, taken for the purposes of the curve at the uniform price of 6d. per unit. The dotted lines show the actual total monthly expenditures during the four years, and the crosses, joined by chain-dotted lines, show the maximum load in kilowatts observed in each year. The moral of this curve is obviously that *the total monthly expenditure is very closely a linear function of the maximum rate at which electricity has to be supplied in a given year*, and that it is in no very obvious way a function of the monthly sales. Those engineers who have not studied the question from this point of view, and who advocate charging at a uniform rate per unit, may be unaware that in most of the fairly-established central stations it is generally found that the total fixed expenditure or standing charges are quite 85 per cent. of the total annual expenditure. For example, the standing charges of the Brighton station in 1895 amounted

Digitized by Google

to about £14,000 out of a total expenditure of £16,500, showing how insignificant (even in a town like Brighton, where coal is so expensive) is the only item varying with the monthly sales when compared to the total annual expenditure.

The other curve (Fig. 2) should be especially interesting to those engineers who are studying the question of the right size of unit to be put down in a central station, and it seems to strongly justify the English practice of having the plant split up into many units of dissimilar size. This curve represents the number of hours in a complete year that a station which has arrived at a certain stage of steady growth will be called upon to supply a load exceeding any given percentage of its maximum load. For instance, it will be seen that a load equal to 95 per cent. of the highest observed in the year was only continued for five hours out of the 8,760 hours in 1895. A load equal to 75 per cent. of the maximum was only placed upon the station for some 250 hours in the year, and a load of 50 per cent. of the maximum for about 750 hours; whilst for 1,500 hours (or for nearly one-fifth of the year) the station had to deal with a 25 per cent. load, and for 3,500 hours (or 40 per cent. of the time) with a 10 per cent. load. Although the shape of this curve will be modified by any improvement of load factor, such a curve forms a very safe basis on which to discuss the proper division of generating plant.

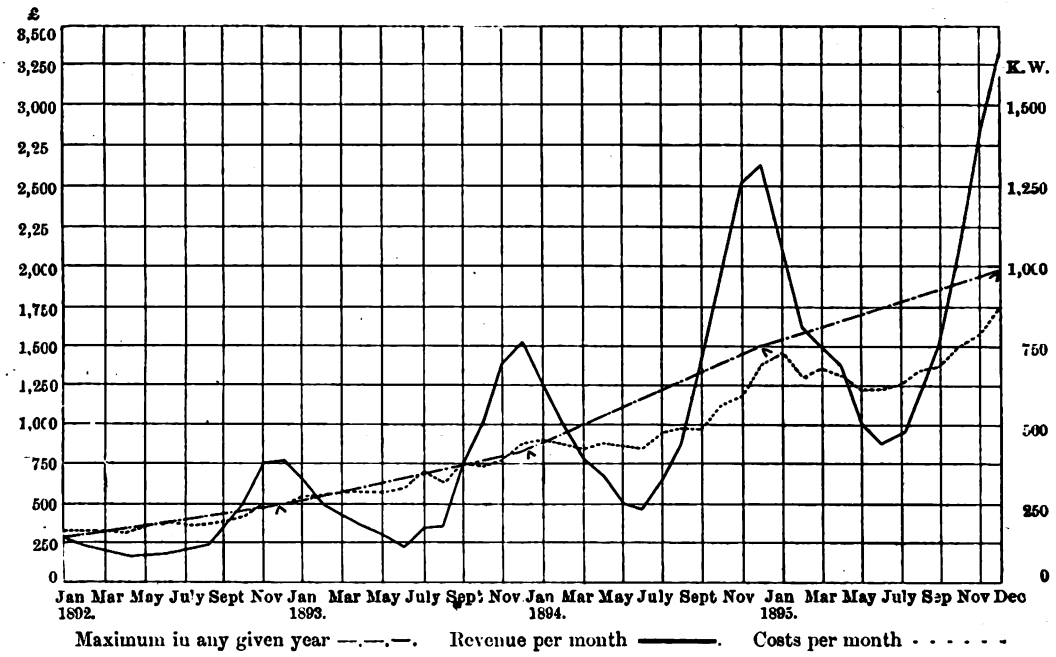

FIG. 1.—Curve showing how monthly expenditure is related with the maximum rate at which Electricity is supplied in any given year, rather than with the monthly sales.

THE NATURE OF CHEMICAL CHANGE AND THE CONDITIONS WHICH DETERMINE IT.*

(Continued from page 487.)

Whatever hypothesis be adopted, the determination of the essential qualities of an electrolyte—a correct answer to the question: What is an electrolyte?—is of fundamental importance. The electricians would say it is a substance which, whilst conducting, undergoes decomposition, which is a purely practical definition. The "ionists" say that it is a substance in a state of ionic dissociation; but theirs is a dissociation of a most mysterious kind—confined to a very limited number of substances—affecting members of the same group in a most arbitrary manner, as whilst some respond, others do not, to the call to ionise on entering into solution—in no way to be co-ordinated with their relative stability as determined by any ordinary chemical method—and conditioned by the agency of a solvent which, though by hypothesis a mere screen, yet exercises a most potent influence, as solvents generally besides this one have little if any action. I discussed the question tentatively at Aberdeen, but did not arrive at any satisfactory conclusion as regards compounds which *per se* act as electrolytes. Facts have since come to light which make me more hopeful. In the case of the metallic protochlorides, so many of which are electrolytes, whilst the corresponding perchlorides are not, electrolysis involves the chloride acting both as electrolyte and "chlorine depolariser," and it is conceivable that the occurrence of decomposition is dependent on, and in a measure condition by, the depolarisation—in other words, that separate molecules are conjointly influenced by the electromotive force, and that while under it the one molecule promotes the decomposition of the other. The readiness with which the silver and lead haloïds undergo electrolysis may be explained in a similar manner, if it be assumed that they are capable of exercising at least a temporary affinity for halogens. It is remarkable that the elements from which electrolysable haloïds are derived occur closely together in the periodic system, and it may be said within the section of the alkali metals. As the alkali metals form tri-iodides, and similar compounds have been obtained from silver haloïds, as well as tetra-haloïd compounds of lead, there is reason to believe that the power of attracting halogens here postulated is actually existent, especially at high temperatures, when the fundamental molecules may be supposed to be more or less free from mutual control, and more likely, therefore, to form compounds with other elements.

From this point of view the behaviour of silver haloïds and of other substances which act as simple electrolytes is strictly comparable with that of composite electrolytes, as I have termed conducting mixtures of dielectrics; and if such a view could be accepted, the phenomenon of electrolysis would appear to be strictly comparable with those of chemical change—both would occur within complex molecular systems. The behaviour of aqueous solutions on electrolysis may conceivably be more analogous to that of haloïds than is commonly supposed, if it should turn out, for example, that, in the case of solutions of sulphuric acid in water, the first products of electrolysis are, as I have tentatively argued (compare *Proceedings*, 1893, 190), hydrogen and *persulphuric acid*. As I will show later on, it would not be difficult to apply a similar hypothesis to other acids and generally to aqueous solutions—especially if water be the *significant* substance in all these changes.

In discussing this, it is necessary to consider the acids themselves, as the suggestion here made in a measure involves the conception that acids such as sulphuric acid are hydrates, not hydroxides. Without attempting to discuss this matter in detail, I may say that, in my opinion, there is no evidence which in any way obliges us to regard sulphuric acid as $SO_2(OH)_2$; on the contrary, all the arguments are equally compatible with the assumption that it is a compound such as may be represented by the formula $SO_3 \cdot OH_2$, in which the radicles SO_3 and OH_2 are still preserved. There is no reason why such a view should not be extended to all "inorganic" acids, and if it be assumed that solutions of the halhydrides contain hydrates, the behaviour of such solutions as acids is strictly comparable with that of acids generally. Organic acids are peculiar in so many ways that they may well also be peculiar in their constitution and different from those derived from elementary oxides.

* Abstract of an address delivered by Dr. H. E. Armstrong before the Chemical Society.

If sulphuric acid be a hydrate, viz., $SO_3 \cdot OH_2$, persulphuric acid is probably $SO_3 \cdot O_2H_2$,* and the formation of the latter during electrolysis as the primary product would, in a sense, involve the oxidation of water, so that the change would be similar in form to that which I have supposed to occur when a silver haloïd is electrolysed. By thus extending the view that electrolysis is the outcome of the combined action of the electromotive force and of some effect which the one set of molecules exerts upon the other set while both are under the influence of the electromotive force, a clearer conception is gained of the possible nature of the effect which the one set of molecules exercises on the other set. The peculiar value of water as a solvent is also in a measure explained.

As regards the differences observed between acids, I have elsewhere pointed out in a note on the formation of salts (*Chem. Soc. Proc.*, 1891, p. 118), that "It may be supposed that in all cases the acid and the base in the first instance combine, and that the salt is formed by subsequent interactions within the molecule. In like manner, acids form dissociable compounds with water, and it is by the occurrence of change within such systems under the influence of an electromotive force that electrolysis is effected. In those cases in which the compound is highly unstable and prone to dissociate, the opportunity for change to take place within the system is but slight, and consequently the acid is a weak one, and its solution of relatively low-conducting power."

The argument here used would apply equally to alkalis and salts, although it may be doubted whether dissolved salts as such promote electrolysis: it is not improbable that they are more or less hydrolysed, and that the products condition electrolysis; on this assumption, the conductivities of salt solutions afford a measure of the extent to which hydrolysis has taken place in them.

Experience shows that action at once necessarily takes place so soon as a conducting circuit is established, provided that the sum of the changes be exothermic—thus, copper readily dissolves in cold dilute sulphuric acid if coupled with platinum in nitric acid, or in presence of oxygen, although the heat of dissolution of copper in sulphuric acid is negative. This principle is one of extraordinary importance, and I desire to draw attention to one illustration of its application which I believe to be of consequence. It is well known that Baeyer in 1870 pointed out that the resolution of glucose during fermentation into alcohol and carbon dioxide, and indeed the phenomena of fermentation generally, may be accounted for by the assumption that translocation of hydrogen and oxygen atoms is induced through the alternate separation of the elements of water and their addition in different order, changes which would involve the accumulation of oxygen atoms at certain parts of the molecule, thus constituting points of weakness where disruption of the molecule would inevitably occur.

The conception is one of remarkable beauty, and undoubtedly a sufficient explanation, as changes precisely similar to those attending fermentation may be effected by simple hydrolysis; thus glucose may be converted into lactic acid by heating it with alkali; and on boiling fructose with muriatic acid an acid is formed, *i.e.*, lævulinic acid, $CH_3 \cdot CO \cdot CH_2 \cdot CH_2 \cdot CO_2H$, the production of which clearly involves a reduction of some of the $CH_2 \cdot OH$ and $CH \cdot OH$ groups, and oxidation of others, in the manner pictured by Baeyer. The only difficulty is to account for the occurrence of such changes under the conditions prevailing during fermentation, and here Baeyer has left the problem unsolved.

It can scarcely be doubted that the truth of Faraday's doctrine of the unity of chemical and electrolytic change will ere long be generally recognised now that it has been shown in so many cases that interaction does not occur between *two* (pure) substances.

The essential moment conditioning the occurrence of chemical change, according to the view of which I am an advocate, is the formation of a conducting system in which electrolysis can occur, and within which, as already said, change will necessarily take place so soon as the system is established, if exothermic change be possible under the conditions—as in the case of any voltaic cell. Substitutions on this hypothesis are but secondary results consequent on additions.

Much has been done of late to discover that water plays an all-important part in determining many chemical changes, but the nature of the influence which it exerts has been little considered, and I am alone, I believe, in pointing out that mere moisture should be insufficient to condition change in many cases—in the formation of water, for example, from hydrogen and oxygen, the interaction of nitric oxdie and oxygen, or the action of chlorine on metals, &c., as in such cases there would not be an electrolyte present. On the other hand, it would presumably suffice to determine the interaction of ammonia and hydrogen chloride, for example, as the latter and water together form an electrolyte. I believe this to be the criterion by which the efficiency of water *per se* may be judged of; in other words, that it will *per se* condition the occurrence of an interaction between two substances only if it be capable of forming a composite electrolyte with at least one of them; in all other cases something besides water must be present which will render the water conducting by forming with it a composite electrolyte. The number of such substances is, as already pointed out, comparatively limited.

In further illustration of this argument, the rusting of iron may be referred to, as notwithstanding its importance and the amount of discussion it has given rise to, the exact nature of the change is by no means determined. According to Crum Brown (*Journal* Iron and Steel Institute, 1888, 2, 129), liquid water, oxygen and carbon dioxide are the essential elements concerned in the formation of rust. But it may well be doubted if a solution of carbon dioxide in pure water be an electrolyte, in which case perhaps the carbon dioxide initially but serves to promote the formation of acid from a trace of some salt which happens to be present, and the primary product derived from the iron is the corresponding iron salt; this last, however, being even more amenable to attack by carbon dioxide than the salt originally present, the acid is continually regenerated. On this view, it is easy to understand the protection afforded by an alkali. I have on more than one occasion urged that probably it is always necessary that liquid-water systems should be formed if change is to occur, at least in the case of changes taking place under ordinary conditions, *i.e.*, at ordinary temperatures. Apparently it is only at high temperatures or under the influence of an electric discharge, that this condition need not be secured, and in such cases it may be supposed that the conditions are such as to favour the momentary formation of what are practically liquid systems in the atmosphere within which the change occurs. It is not improbable that the influence which surfaces often exercise in promoting gaseous changes may at least in some part be due to the increased opportunity they afford for the formation of liquid systems to take place.

The absolute function which the (composite) electrolyte fulfils in such systems is obscure at present, as it is but stating a fact to say that the presence of a conductor is essential in order that a current may flow: it would seem not improbable that it in some way constitutes a mechanism whereby the discharge or degradation of the energy expended in the change is effected. The question is one of great interest and importance, especially when viewed in connection with the inquiry into the nature of valency and with the fact that an action impossible within an endothermic system at once takes place when an element (a depolariser) is introduced which constitutes the system one within which as a whole endothermic change can occur.

H. B. Dixon's observations on the combustion of carbonic oxide, as well as those of Victor Meyer and his co-workers on the formation of water, and also those of Pringsheim, followed by those of Victor Meyer and Bodenstein, on the formation of hydrogen chloride, all bring into prominence the fact that the occurrence of change in gases is dependent on conditions which are essentially of the same order as those obtaining in the case of liquids. Prof. J. J. Thomson's observations on the discharge of electricity through gases (*Phil. Mag.*, 1893, 36, 313) apparently prove that what is true of chemical change is equally true of the electrical discharges which can be produced in rarefied gases—that the phenomena in both cases, in fact, are electrolytic manifestations, and that discharge could not take place in a pure gas. It appears to me unnecessary to assume that such changes are dependent on the occurrence of atomic dissociation of the molecules of the interacting substances prior to the formation of the molecules of the substances which are the ultimate products; indeed, the observations referred to may almost be regarded as proof that such is not the case. No more striking evidence that the occurrence of a discharge in a gas is dependent on the presence of a something besides the gas—on the formation of a complex conducting system—could be given than is afforded by the beautiful experiment exhibited by Dewar at the Royal Institution, showing that the discharge at once ceases in one of Crookes's phosphorescent tubes on cooling with liquid oxygen. Such treatment cannot be supposed to cause the condensation of the residual air, but may well condition the deposition of the traces of vapour (? of conducting water) present in the gas, thereby destroying the systems within which conduction can alone occur.*

* Berthelot has actually obtained a persulphate from sulphuric anhydride and a peroxide.

* It is noteworthy that J. J. Thomson himself draws the conclusion from his experiments that the discharge through a gas does not consist in tearing the atoms of a single molecule apart, but rather in tearing atoms from off complex aggregates of molecules. I may here point out, with reference to his observation, that a much higher potential difference is required to start a discharge in a highly dried gas than is required to maintain the discharge when once it has taken place, that if a trace of air were present a trace of nitric acid would be formed, which might render the minute amount of moisture present conducting; during rest this would be attracted to the walls of the tube, and therefore it would be at first difficult again to start the discharge, as indeed he found to be the case.

Digitized by Google

It may be here pointed out that this argument is perhaps also at least partially applicable in explanation of the erratic behaviour of the discharge in vacuum tubes. If the discharge occur within a complex system, it may well be that certain conditions will favour the formation of a conducting system including one, and others of a system including another, of several substances present in a tube—such an explanation, for example, would account for the fact that the mercury spectrum is only sometimes seen in tubes connected with a mercury pump. And having regard to the fact that a gas may exhibit several spectra, it may be that the spectrum of a given substance varies more or less according as it is included in one or other of several conducting systems.

If the occurrence of chemical change be dependent on the formation of liquid or quasi-liquid systems, the reduction of temperature sufficiently to produce solidification should prevent change. This is probably the explanation of observations such as have been made by Dewar and Pictet. There is probably no more effective method of drying, if drying be defined as the removal of liquid water, than that afforded by cooling to the very low temperatures obtained with the aid of liquid oxygen. In like manner, I am inclined to doubt whether any photographic action be possible at very low temperatures, and would attribute the slight effect observed by Dewar to the action of the phosphorescent light emitted by the plate itself on the sensitive film after the temperature has risen sufficiently for the water within the film again to become liquid. I have long been convinced that photographic phenomena and procedure can and should be treated from the electrolytic point of view (*Camera Club Journal*, 1892, 61, 124; 1893, 48, 71).

We are but beginning to recognise that what is true of ordinary interchanges, *i.e.*, that the change takes place with a complex conducting system, must be equally true of changes of the converse order, so-called decompositions, including dissociation phenomena generally. Among the chief experimental contributions to our knowledge of this subject, we may reckon first and foremost the classical work of Grove on the decomposition of water at high temperatures, and the observations of Deville, as well as those of Victor Meyer and Langer, showing that the decomposition of carbon dioxide takes place in porcelain at a temperature several hundred degrees below that at which it occurs in platinum vessels. Perhaps Frederick Siemens, more than anyone, has dwelt on the influence of conditions other than those of mere temperature on the stability of substances at high temperatures.

It must always appear paradoxical that water should undergo decomposition at a temperature which necessarily must be below that which can be developed in its formation by combustion from hydrogen and oxygen; or, assuming that the effect is primarily of an electrical character, that it should be decomposed by an electromotive force lower than that which can be developed by the interaction of the elements into which it is resolved.

The problem is akin to that involved in the electrolysis of water, which can be effected by electromotive forces much smaller than about 1·4 volts, the value calculated from the known heat of formation of water.

Two explanations are possible—one involving the assumption of dissociation, the other of an available external source of energy; it is needless to say that the former has long been the popular view. Reference has already been made to current views on the dissociation of water, and the question raised whether we are justified in concluding that water under ordinary conditions is dissociated, even to a very slight extent. But whatever the ultimate conclusion, even if pure water be undissociated and an absolute dielectric, it may well be that in the case of a conducting mixture we are dealing with systems which, although free from any elements of dissociation, may yet be prone to undergo internal changes much after the manner of those pictured by Williamson in his celebrated essay on etherification (*J. Chem. Soc.*, 1851, 4, 110), changes which, as Fitzgerald has pointed out, would in effect be of the same order as those postulated by the modern school of dissociationists. On the other hand it is not impossible that our conclusions are all based on observations made either with polarised electrodes or with media which have been to some extent impure.

In the experiment devised by Helmholtz and described in his Faraday lecture, the attempt was made, by means of an additional electrode of palladium which could be charged with hydrogen, to remove all traces of dissolved oxygen, and this object is supposed to have been effected; but I venture to doubt the possibility of securing complete depolarisation in such a manner.

With regard to its behaviour at high temperatures, if pure water be to some slight extent dissociated, even under ordinary conditions, as is suggested, it may fairly be expected that it would undergo further dissociation, to a greater extent and more readily than appears to be the case, as the temperature is raised; the important experiments made by V. Meyer and Langer on the behaviour of various gases at very high temperatures apparently also lend no support to this view. The dissociation of water takes place more particularly in contact with heated platinum—copper, although readily oxidised, appears to have no specific influence in promoting its decomposition. Platinum, however, occludes both hydrogen and oxygen and may be supposed to be always charged with one or other of these gases—so that if the decomposition of water at high temperatures by platinum take place within a circuit including one or other of these gases, the electromotive force required to produce the change will be lower than that developed in the formation of water owing to the operation of a back electromotive force. It may be that heated copper does not decompose water, both because it does not polarise as does platinum, and perhaps, also, because the heat of formation of its oxide is lower than that of water under all conditions.

H. B. Baker's observations on the influence of moisture on the decomposition of ammonium chloride by heat (*Trans.*, 1894, 65, 615) are of great importance as the first of their kind, and must serve to direct attention to the value of further experiments of a similar character. It does not appear to me that we are yet justified in assuming that if dry such a substance would not decompose if heated; should we not, perhaps, rather consider that it would decompose somewhat suddenly when a sufficiently high temperature was reached—when the temperature was, in fact, a trifle higher than that corresponding to its heat of formation? The presence of moisture would promote decomposition because it is capable of interacting exothermically with one of the products—viz., hydrogen chloride. As change is influenced in both directions by moisture, the rate at which it would proceed in a case like that of ammonium chloride would, therefore, depend on the amount of moisture present; if the amount were very small the pressure of dissociation would be attained only after the lapse of a considerable interval of time. The interesting account recently given by Rose (*Trans.*, 1895, 61, 893) of his observations on the influence of moisture on the pressure of dissociation of gold chloride—the first of their kind made to test this view—I think, clearly appears to afford confirmation of the correctness of this conclusion. With reference to this question, it may be here suggested that the occurrence of but slight decomposition when calcium carbonate is strongly heated in almost closed vessels may be due not only to the fact that under such conditions the maximum opportunity is given for recombination, but also to the almost complete exclusion of moisture under such conditions. The practice of burning chalk wet is calculated to favour the maintenance of the "back electromotive force" developed in the interaction of lime and water to the utmost possible extent, and thus to hasten the rate of change; in other words, the acceleration is not the outcome of the removal of the gaseous products of change alone. Similar considerations apply to the incomplete *per saltum* combustion of gaseous mixtures at high temperatures.

It is an interesting question whether compounds such as potassium chlorate, which decompose exothermically, will be affected by the presence of moisture or substances exercising equivalent effects; and this inquiry is clearly of special importance in connection with that into the stability of explosives. Baker's experiments have afforded negative results, but the subject is deserving of much closer experimental study. In such cases we are dealing with closed systems in a measure comparable with a charged Leyden jar, in which there are parts capable of interacting kept asunder by a non-conductor. The question is whether change be induced by communication being set up between these distant parts by the interposition of an external conductor, or, in other words, the completion of a circuit; or whether it be the outcome of a disturbance similar to that which would have the effect in the case of a Leyden jar of smashing aside the dielectric at some point, and consequently of bringing into contact the two coatings previously kept apart. The manner in which the decomposition of potassium chlorate is promoted by the presence of various substances might be regarded as evidence in favour of the former view were it not that anything which would give rise to changes developing a back electromotive force would at once alter and of course increase the rate of change; and such actions are clearly not impossible in the case in question. It would be a matter of great interest to closely study the behaviour of some of the complex carb-oxylic acids which lose carbon dioxide when heated, or of the keto-acids from which carbon monoxide is evolved, with the object of ascertaining whether the rate of change is in any way dependent on the amount of impurity present—whether, in fact, such compounds would prove to be the more stable the greater the care taken in their purification, including dehydration under purification; but it is not to be expected that positive results will be attained in such cases until the approach to purity becomes very close. In the case of single substances undergoing rearrangement of parts, it is not unlikely that "residual affinity" may come into play as much as it does in the case of ordinary interactions, and therefore that such decompositions will equally depend on the realisation of particular conditions; in other words, that the stability of compounds ordinarily reckoned very unstable may be very considerable in the pure state.

The instability of liquid ozone, to which attention has been drawn by Dewar and Liveing's observations, for example, may not

Digitized by Google

be an intrinsic property of ozone in the liquid state, but may be conditioned by the circumstance that, being liquid, it is more readily brought into circuit or coupled up with impurities which happen to be present, so that opportunity is given for change to set in. The decomposition of liquid ozone would seem, in fact, to be comparable with that of a liquid system of sulphur dioxide, oxygen and water, in which change occurs somewhat readily, although a gaseous mixture of the same substance is stable, according to H. B. Dixon.

Of the many directions in which the introduction of electrical conceptions into chemistry promises to be of service, the determination of the "electromotive efficiency" of chemical change appears to be one of the most important.

Braun in Germany, and in this country Alder Wright, whose loss we so much deplore, have devoted much attention to the determination of "chemical affinity" in terms of electromotive force, following the method first adopted by William Thompson (now Lord Kelvin), and successfully applied by him to the Daniell cell. Thomson's calculations involved the assumption that the energy of chemical change becomes wholly converted into electrical energy, but the comparisons which have been since made *seem* to show that in cells other than the Daniell this is rarely, if ever, the case. Helmholtz and others, in fact, have proposed to draw a distinction between free and bound energy, the latter being that portion of the total energy of the system which is not convertible into electrical energy, but becomes frittered down into heat in chemical changes. It has always seemed to me that most physicists who have discussed these matters have had far too little feeling as regards the nature of chemical changes, and that the conclusions have been too often based on *à priori* considerations. Obviously, it is necessary to know the precise character of the changes going on under particular conditions in any cell before the attempt can be made to ascertain whether the electromotive force developed is the precise equivalent of their "chemical energy." Our knowledge as to what goes on in solutions is so vague, however, that at present we can never assert that we know precisely what is happening in a particular system. As Herroun has pointed out in an important Paper on "The Divergence of Electromotive Forces from Thermochemical Data" (*Phil. Mag.*, March, 1889, 209), there is reason to believe that in the case of a number of metals, silver and mercury, for example, it is probably altogether wrong to base calculations on the assumption that the heat of formation of a hydrated salt, or of the salt in a solution of the concentration of that which is ultimately formed in the cell in which the metal is dissolved, is the heat of formation to be made use of in the calculation of electromotive force; we must, in many cases, rather assume that the anhydrous salt is alone formed in the circuit. In like manner, Robertson and I have contended (*Roy. Soc. Proc.*, 1891, 50, 108) that in the lead-sulphuric acid-lead peroxide cell the active acid is not that actually filled in, but a lower hydrate or the anhydrous acid; in this manner it is possible to account for the cooling observed during the discharge of an "accumulator," as the separation of molecules of the acid from a solution (by dissociation) would, of course, involve cooling.

If, as Faraday has said, the forces termed chemical affinity and electricity are one and the same, there does not seem to be any reason why there should not be an integral conversion of the energy of chemical change, nor any necessarily valid objection to the view than an explanation of the discrepancies which have been observed is to be sought for in phenomena that prevent an integral "conversion" from being realised. Meanwhile, the determination of electromotive force may be of great service as enabling us to discriminate between a number of conceivable modes in which change may occur in a given case. Thus it is clear, for example, that whereas a metal like zinc is dissolved by, say, sulphuric acid in a circuit of which the hydrated, not the anhydrous, acid forms a part, metals like silver, mercury, lead and even nickel (compare Herroun, *loc. cit.*, p. 226) require to be coupled with, it may be, the anhydrous acid, but in any case, with one which is less hydrated than that which is active in the case of zinc; the anhydrous salts formed in such cases apparently undergo hydration outside the circuit of electrolytic change, and their hydration only affects the temperature of the cell, so that the phenomena are comparable with those which attend local action in a cell in which ordinary or imperfectly amalgamated zinc is used.

In other words, it is not a mere question as to what is present in a solution; the *compatibility* of the various substances must also be considered, and of this we know very little at present. Incompatible molecules may get in the way and hinder change, but only compatible molecules can co-operate in changes, so that we cannot simply write $C=\frac{E}{R}$, and treat R as the resistance of the solution as a whole in which the change takesplace; it may of ten be the resistance of circuits within the solution, the precise nature of which it is difficult, if not impossible, to determine.

It is impossible to doubt that, as a means of determining the precise character of the changes which may be going on in a complex system, the determination of the electromotive efficiency of various combinations will prove to be of the utmost importance. As a further illustration of the manner in which we may derive assistance from the introduction of such physical considerations, attention may be directed to the complex changes attending the action of metals on nitric acid, a subject which has long troubled the minds of chemists, and which has always exercised a special fascination over me. There is little, probably no hope, that we shall ever arrive at a satisfactory solution of this complex problem, so long as we regard it from a purely chemical point of view.

The observations of fundamental importance which must be first taken into account in discussing such changes are those of Millon (1842), Russel (1874) and Veley (1891), showing that silver, copper, &c., are not soluble in nitric acid free from nitrous compounds. In my opinion, however, these observations cannot be regarded as proof that nitrous acid is the solvent of the metal; the conclusion to be derived from them, I think, is of a far more interesting character.

Silver has a negative heat of dissolution, the value calculated from the data given by Thomsen being (at 18deg.):—

$$2Ag+2HNO_3, Aq = -51{,}580 \text{ gram-deg. C. units.}$$

This value, however, is reduced to - 40,700 if the heat of dissolution of silver nitrate be deducted. As the reduction of nitric acid to nitric peroxide ($2HNO_3 - O = N_2O_4, H_2O$), according to Thomsen, involves an expenditure of but 10,010 units, the oxidation by *nitric acid* of the hydrogen displaced by silver dissolving in nitric acid would give $68{,}360 - 10{,}010 = 58{,}350$ units, which is considerably in excess of the value $-51{,}580$, and still more so if the lower value corresponding to the formation of the anhydrous salt be taken. Silver, therefore, should be easily soluble in nitric acid if this acid can act as a *depolariser*. A still stronger case may be made out by considering the values for mercury and copper, as the heats of dissolution of these metals, although negative, are considerably lower than that of silver. Such facts appear to leave little room for doubt, and to justify the important conclusion that the nitrous compound is the active depolariser.

To conclude that such metals as bismuth, copper, mercury and silver are dissolved by nitrous acid, not by nitric acid, is to attribute to nitric acid properties which would make it entirely peculiar among acids, for it appears to be a characteristic property of acids generally to dissolve metals generally whenever the conditions are such that exothermic change can occur.

It seems to me that such problems can only be treated from an electrolytic standpoint, and the fact that we do not always so treat them is evidence of a most extraordinary failure on the part of chemists to apply Faraday's teachings. Unfortunately the physicists have also neglected this subject, having apparently left it to the chemists to discuss the changes attending the interaction of metals and acids; the result is blank ignorance of all that is fundamental with regard to such matters on the part of both chemists and physicists.

Objection has been taken to the use of the hypothesis of nascent hydrogen in explaining the effects produced with nitric acid. No doubt the conception is much misunderstood and misused; but it is, after all, a conception which cannot be put aside. Hydrogen undoubtedly is often displaced and brought into action without ever escaping from the circuit in which, and along which, it is displaced; "nascent" hydrogen, in fact, is but hydrogen in circuit, the hydrogen which is active at the surface of the plates in a Grove's gas battery, or which effects reduction when condensed in charcoal, being as much "nascent" in this sense as that displaced from water, say, by sodium amalgam in presence of a reducible substance. Moreover, the "activity" of such hydrogen depends entirely on its origin. This cannot be denied in face of the fact that if in cells of the Daniell type, for example, cadmium be substituted for zinc, not only is the electromotive force developed lower, but lower to the extent to which the heat of dissolution of cadmium in the acid used is less than that of zinc.

In dissolving metals in nitric acid we are but dealing with "cells" of the Grove type. If nitrous acid be in any way directly active as solvent of the metal, in all probability it can but act along with the nitric acid, and not to its exclusion; but it is useless to discuss this question further until we are sure that nitrous acid actually exists, and there is much reason to doubt this. As copper is readily dissolved by diluted sulphuric acid in presence of oxygen, although insoluble in the acid alone, it is inconceivable that nitric acid should not be equally active in presence of a sufficiently active depolariser—when the conditions are such, in fact, as are secured by the presence of oxygen together with copper and sulphuric acid, and a system is formed within which exothermic change is possible.

In all cases of chemical change energy is ultimately degraded, but in most cases a switchback rather than a simple inclined plane is the graphic analogue of a circuit of chemical change. Or, still better, we may liken it to a system of pipes laid up and down hill through which water is supplied to a town, in which case the function of the depolariser is comparable with that of the stand-

Digitized by Google

pipe or accumulator at the pumping station, up and through which the water is forced in order to secure the head which is necessary to overcome the friction in the pipes and to cause water to mount the hills in the district supplied, as well as to raise it to the tops of the houses and in the fire mains. Such hydraulic systems can only be constructed of pipes which can be fitted together, just as chemical changes can only be brought about between compatible substances. Lastly, those who enjoy a constant service have no right to assume that the supply of water is automatic; on the contrary, a complex organisation which may altogether escape notice is required to secure it. And so it may be in the case of electrolysis and chemical change.

(To be concluded).

HIGH-VACUA RESEARCH.*

During the 56 years which have passed since Faraday first offended physical mathematicians with his curved lines of force, many workers and many thinkers have helped to build up the nineteenth century school of *plenum;* one ether for light, heat, electricity, magnetism; and the German and English volumes containing Hertz's electrical Papers given to the world in the last decade of the century, will be a permanent monument of the splendid consummation now realised. But, splendid as this consummation is, we must not fold our hands and think or say there are no more worlds to conquer for electrical science. We do know something now of magnetic waves. We know that they exist in nature and that they are in perfect accord with Maxwell's beautiful theory. But this theory teaches us nothing of the actual motions of matter constituting a magnetic wave. Some definite motion of matter perpendicular to the lines of alternating magnetic force in the waves and to the direction of propagation of the action through space there must be; and it seems almost satisfactory as a hypothesis to suppose that it is chiefly a motion of ether with a comparatively small but not inconsiderable loading by fringes of ponderable molecules carried with it. This makes Maxwell's "electric displacement" simply a to-and-fro motion of ether across the line of propagation—that is to say, precisely the vibrations in the undulatory theory of light according to Fresnel. But we have as yet absolutely no guidance towards any understanding or imagining of the relation between this simple and definite alternating motion, or any other motion or displacement of the ether, and the earliest known phenomena of electricity and magnetism—the electrification of matter, and the attractions and repulsions of electrified bodies; the permanent magnetism of lodestone and steel, and the attractions and repulsions due to it; and certainly we are quite as far from the clue to explaining, by ether or otherwise, the enormously greater forces of attraction and repulsion now so well known after the modern discovery of electromagnetism.

Fifty years ago it became strongly impressed on my mind that the difference of quality between vitreous and resinous electricity, conventionally called positive and negative, essentially ignored as it is in the mathematical theories of electricity and magnetism with which I was then much occupied (and in the whole science of magnetic waves as we have it now), must be studied if we are to learn anything of the nature of electricity and its place among the properties of matter. This distinction, essential and fundamental as it is in frictional electricity, electro-chemistry, thermo-electricity, pyro-electricity of crystals, and piezo-electricity of crystals, has been long observed in the old known beautiful appearances of electric glow and brushes and sparks from points and corners on the conductors of ordinary electric machines and in exhausted receivers of air pumps with electricity passed through them. It was also known, probably as many as 50 years ago, in the vast difference of behaviour of the positive and negative electrodes of the electric arc lamp. Faraday gave attention to it[1] in experiments and observations regarding electric sparks, glows and brushes, and particularly in his "dark discharge" and "dark space" in the neighbourhood of the negative electrode in partial vacuum. In [1523] of his 12th Series he says: "The results connected with the different conditions of positive and negative discharge will have a far greater influence on the philosophy of electrical science than we at present imagine." His "dark discharge" ([1544—1554]) through space around or in front of the negative electrode was a first instalment of modern knowledge in that splendid field of experimental research which, 15 years later, and up to the present time, has been so fruitfully cultivated by many of the ablest scientific experimenters of all countries.

The Royal Society's *Transactions* and *Proceedings* of the last 40 years contain, in the communications of Gassiot,[2] Plücker,[3] Andrews and Tait,[4] Robinson,[5] Cromwell Varley,[6] De la Rue and Müller,[7] Spottiswoode,[8] Moulton,[9] Grove,[10] Crookes,[11] Schuster,[12] J. J. Thomson,[13] and Fleming,[14] almost a complete history of the new province of electrical science which has grown up, largely in virtue of the great modern improvements in practical methods for exhausting air from glass vessels, culminating in Sprengel's mercury-shower pump, by which we now have "vacuum tubes" and bulbs containing less than 1/190,000 of the air which would be left in them by all that could be done in the way of exhausting (supposed to be down to 1mm. of mercury) by the best air pump of 50 years ago. A large part of the fresh discoveries in this province has been made by the authors of these communications; and their references to the discoveries of other workers very nearly complete the history of all that has been done in the way of investigating the transmission of electricity through highly-rarefied air and gases since the time of Faraday.

Varley's short Paper of 1871, which, strange to say, has lain almost or quite unperceived in the *Proceedings* during the 22 years since its publication, contains an important first instalment of discovery in a new field—the molecular torrent from the "negative pole," the control of its course by a magnet, its pressure against either end of a pivoted vane of mica according as it is directed by a magnet to one end or the other, and the shadow produced by its interception by a mica screen. Quite independently of Varley, and not knowing what he had done, Crookes[15] was led to the same primary discovery, not by accident, and not merely by experimental skill and acuteness of observation. He was led to it by carefully-designed investigation, starting with an examination of the cause of irregularities which had troubled[16] him in his weighing of thallium; and, going on to trials for improving Cavendish's gravitational measurement, in the course of which he discovered that the seeming attraction by heat is only found in air of greater than 1/1,000[17] of ordinary density; and that there is repulsion increasing to a maximum when the density is decreased from 1/1,000 to 36/1,000,000, and thence diminishing towards zero as the rarefaction is farther extended to density 1/20,000,000. From this discovery Crookes came to his radiometer, first without and then with electrification; and, powerfully aided by Sir George Stokes,[18] he brought all his work more and more into touch with the kinetic theory of gases; so much so that when he discovered the molecular torrent he immediately gave it its true explanation—molecules of residual air, or gas, or vapour projected at great velocities[19] by electric repulsion from the negative electrode. This explanation has been repeatedly and strenuously attacked by many other able investigators, but Crookes has defended[20] it, and thoroughly established it by what I believe is irrefragable evidence of experiment. Skilful investigation perseveringly continued brought out more and more of wonderful and valuable results: the non-importance of the position of the positive electrode; the projection of the torrent *perpendicularly* from the surface of the negative electrode; its convergence to a focus and divergence thenceforward when the surface is slightly concave; the slight but perceptible repulsion between two parallel torrents due, according to Crookes, to negative electrifications of their constituent molecules; the

change of direction of the molecular torrent by a neighbouring magnet; the tremendous heating effect of the torrent from a concave electrode when glass, metal, or any ponderable substance is placed in the focus; the phosphorescence produced on a plate coated with sensitive paint by a molecular torrent skirting along it; the brilliant colours—turquoise-blue, emerald, orange, ruby-red—with which grey colourless objects and clear colourless crystals glow on their struck faces when lying separately or piled up in a heap in the course of a molecular torrent; "electrical evaporation" of negatively electrified liquids and solids;[21] the seemingly red-hot glow, but with no heat conducted inwards from the surface, of cool solid silver kept negatively electrified in a vacuum of 1/1,000,000 of an atmosphere, and thereby caused to rapidly evaporate. This last-mentioned result is almost more surprising than the phosphorescent glow excited by molecular impacts in bodies not rendered perceptibly phosphorescent by light. Both phenomena will surely be found very telling in respect to the molecular constitution of matter and the origination of thermal radiation, whether visible as light or not. In the whole train of Crookes' investigations on the radiometer, the viscosity of gases at high exhaustions, and the electric phenomena of high vacuums, ether seems to have nothing to do except the humble function of showing to our eyes something of what the atoms and molecules are doing. The same confession of ignorance must be made with reference to the subject dealt with in the important researches of Schuster and J. J. Thomson on the passage of electricity through gases. Even in Thomson's beautiful experiments showing currents produced by circuital electromagnetic induction in complete poleless circuits, the presence of molecules of residual gas or vapour seems to be *the essential*. It seems certainly true that without the molecules there could be no current, and that without the molecules electricity has no meaning. But in obedience to logic I must withdraw one expression I have used. We must not imagine that "presence of molecules is *the* essential." It is certainly *an* essential. Ether also is certainly *an* essential, and certainly has more to do than merely to telegraph to our eyes to tell us of what the molecules and atoms are about. If a first step towards understanding the relations between ether and ponderable matter is to be made, it seems to me that the most hopeful foundation for it is knowledge derived from experiment on electricity in high vacuum; and if, as I believe is true, there is good reason for hoping to see this step made, we owe a debt of gratitude to the able and persevering workers of the last 40 years who have given us the knowledge we have; and we may hope for more and more from some of themselves and from others encouraged by the fruitfulness of their labours to persevere in the work.

NEW PROPERTIES OF CATHODE RAYS.*

BY JEAN PERRIN.

(I.) Two hypotheses have been brought forward to explain the properties of cathode rays. Some, like Goldstein, Hertz and Lenard, think that the phenomenon, like light, is due to etherial vibrations[1] and even that it is short-wave light. From this it would follow that these rays would have rectilinear propagation, would excite phosphorescence, and impress photographic plates. Others, like Crookes and J. J. Thomson, think the rays are due to negatively-charged matter moving at a high speed. From this their mechanical properties would follow, also the manner in which they are deflected in a magnetic field. This last hypothesis suggested certain experiments to me which I propose to briefly describe without troubling myself for the moment whether the hypothesis accounts for all the facts known up to the present or whether it alone can do so. The supporters of this hypothesis assume that the cathode rays are negatively charged. So far as I know, this electrification has not been ascertained. I, therefore, first tried to discover whether or no it existed.

(II.) To effect this I had recourse to the laws of influence, which enable us to ascertain the introduction of electric charges within a closed conducting envelop and to measure these charges. I therefore caused the cathode rays to penetrate into a Faraday cylinder. To this end I employed the vacuum tube represented in Fig. 1, in which A B C D is a metallic cylinder closed everywhere except at a little opening in the centre of the face B C. This played the part of the Faraday cylinder. A metal wire soldered at S to the wall of the tube placed the cylinder in communication with an electroscope. E F G H is a second metallic cylinder *in permanent communication with earth* and pierced only by two small openings at β and γ. It protects the Faraday cylinder against all external influence. Finally at about 0·1 metre in front of F G there is an electrode N, which served as the cathode, the anode being formed by the protecting cylinder E F G H.

When a cathode beam penetrated into the Faraday cylinder it invariably became charged with negative electricity. The exhausted tube could be placed between the poles of an electro-magnet. When this was excited the cathode rays, being deflected, no longer entered the Faraday cylinder and the cylinder was not charged; it became charged the moment the electro-magnet was no longer excited.[2] In short, the Faraday cylinder is negatively charged when the cathode rays penetrate it, and only when they do so: *cathode rays are therefore charged with negative electricity.*

It is possible to measure the quantity of electricity which these rays convey. I have not completed this investigation, but I may give an idea of the order of the amount of the charges obtained when I state that with one of my tubes at a pressure of 20 microns[3] of mercury, and for a single interruption of the primary coil, the Faraday cylinder received sufficient electricity to bring a capacity of 600 C.G.S. units to a potential of 300 volts[4].

(III.) Cathode rays being negatively charged, the principle of the conservation of energy induced me to search for the corresponding

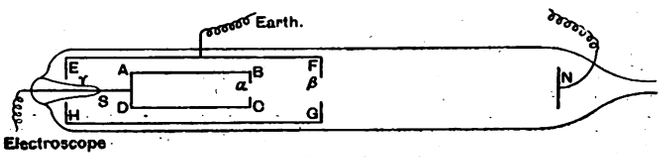

FIG. 1.

positive charges. I believe I have found them in the very region where the cathode rays are generated, and that they travel in the reverse direction and precipitate themselves on to the cathode.

To verify this hypothesis we have only to make use of a hollow cathode, pierced by a small aperture, through which the attracted positive Electricity may enter. This electricity can then act on a Faraday cylinder inside the cathode. The protecting cylinder E F G H, with its opening β, fulfilled these conditions. I therefore employed it this time as cathode, the electrode N being the anode. The Faraday cylinder was then invariably charged with *positive electricity* of the same order of quantity as the previously-obtained negative charge. Hence at the same time that the negative electricity is radiated from the cathode; positive electricity travels towards the cathode.

I experimented to discover whether this positive flux formed a second system of rays absolutely symmetrical with the first.

(IV.) For this purpose I constructed a tube (*see* Fig. 2) analogous to the first, with the exception that between the Faraday cylinder and the opening β there was a perforated metallic diaphragm, β', so that the positive electricity which had entered through β could only act on the Faraday cylinder by traversing also the diaphragm β'. I then repeated my former experiments.

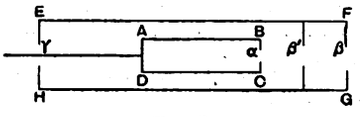

FIG. 2.

When N was the cathode the cathode rays emitted traversed the two apertures at β and β' without any difficulty, and caused the gold leaves of the electroscope to diverge widely. But when the protecting cylinder was the cathode, the positive flux, which, as was shown by a previous experiment, enters by the aperture β, did not succeed in separating the gold leaves, except at very low pressures. If we substitute an electrometer for the electroscope we shall see that the action of the positive flux is real, but that it is very small, and increases as the pressure decreases. In a series of experiments at a pressure of 20μ this action brought a capacity of 2,000 C.G.S. units to 10 volts, and at a pressure of 3μ, in the same time, to 60 volts.[5]

By means of a magnet the action could be completely suppressed.

(V.) These results, taken as a whole, do not appear to be easily reconcilable with the theory that cathode rays are ultra-violet light. On the contrary, they support the theory that attributes these rays to radiant matter, a theory which may at present, it seems to me, be enunciated as follows:—In the vicinity of the cathode the electric field is sufficiently strong to tear asunder *into ions* some of the molecules of the residual gas. The negative ions start off

Roy. Soc. Proc., June 11, 1891.

* *Comptes Rendus*, Vol. CXXI., No. 27, p. 1130.

[1] These vibrations might be something else than light. Quite recently Herr Jaumann, whose hypotheses have been criticised by M. H. Poincaré, suggested longitudinal vibrations.

[2] All these experiments succeeded equally well with an induction coil or with a Wimshurst machine.

[3] [1 micron = 10^{-6} mètre = $\frac{1}{1000}$th of a millimetre.—ED. *E.*]

towards the region where the potential increases, acquire a considerable velocity and form cathode rays; their electric charge, and consequently their mass (at the rate of one gramme-equivalent per 100,000 coulombs), is easily measured. The positive ions move in the reverse direction; they form a diffused tuft, susceptible to magnetism, but are not a regular radiation.[6]

ALL SORTS AND CONDITIONS OF RAYS.

The *Comptes Rendus* for January 27th and February 3rd contain numerous communications on X and other rays, of which communications we give a brief summary below :—

On. p. 188 of the *Comptes Rendus* for January 27th there is a Paper by M. Gustave Le Bon, entitled "Dark Light." M. Le Bon states that recent announcements on the subject of the photographic power of rays emanating from the cathode compels him to make public some researches, still incomplete, which he has been carrying out for the past two years on photography behind bodies opaque to ordinary light. M. Le Bon states that his experiments prove that ordinary light, or at least certain rays, traverse the most opaque bodies without difficulty. "Opacity is a phenomenon which only exists for an eye like ours; constructed a little differently, it could see through a brick wall."

The following is M. Le Bon's own description of what he has done :—"In an ordinary positive photographic frame introduce a sensitive plate, and above it a photographic *cliché*, then above the *cliché*, and in intimate contact with it a sheet of iron entirely covering the front face of the frame. Expose the plate thus masked by the metal sheet to the light of a petroleum lamp for about three hours. A strong and very prolonged development of the sensitive plate, pushed to complete blackening, will give a very pale but very clear image of the *cliché*. We need only slightly modify the previous experiment to obtain images almost as good as if no obstacle had been interposed between the source of light and the sensitive plate. Without altering the arrangement just described, place behind the sensitive plate a sheet of lead of any thickness and bend down its edges so that they just cover the sides of the iron plate. The sensitive plate and the *cliché* are thus imprisoned in a sort of metal box, the front of which is formed by the sheet of iron, and the back and sides by the sheet of lead. After three hours' exposure to the light of the petroleum lamp, as before, we shall obtain, after development, a good image. . . . Solar light yields the same results as a petroleum lamp, and does not appear to be very much more active. Cardboard and metals, especially iron and copper, are easily traversed by light. The passage of light through the most opaque bodies is only a question of time."

In the *Comptes Rendus* for February 3rd, p. 233, M. Le Bon describes the precautions who took to eliminate any possible effect due to light "stored up" by the *clichés* previous to the experiment. He only employed *clichés* which had been in contact with the sensitive plate in the dark for a whole day without producing any effect. As to heat being a possible cause of the phenomenon, M. Le Bon kept sensitive plates in contact with *clichés* for 12 hours at a temperature of 50°C. without getting a trace of an image. Photographic effects have been obtained by M. le Bon through aluminium, copper and iron sheets from 0·5mm. to 0·8mm. thick. Photographers' black paper, in spite of it being only about 0·02mm. thick, is only slightly transparent to these rays, whilst, as will be remembered, it is very transparent to cathode rays.

On p. 235 of the same number, MM. L. Benoist and D. Hurmuzescu present a Paper on "New Properties of the X-rays." These gentlemen experimented on the effects of X-rays on an electrically-protected electrified Hurmuzescu electroscope about 20cm. distant from the Crookes tube. Using various laminæ in the window of the metallic cover of the electroscope, they found that X-rays immediately and completely discharged the electroscope, though *more rapidly in the case of negative charges than in the case of positive.*

On p. 237 M. Albert Nodon states that he finds he cannot get any appreciable impression on a sensitive gelatino-bromide of silver plate exposed for 15min. behind several thicknesses of black paper to a 20-ampere arc at a distance of 40cm. Using orthodox Röntgen rays he finds that they are not differentially affected by differently coloured media—all colours appear to come alike to Röntgen rays.

On p. 237 M. V. Chabaud describes some experiments on the transparency of rectangular metallic laminæ, 0·2mm. thick, 35mm. long, 7mm. broad, arranged side by side on a piece of cardboard, and crossed by a transverse lamina of platinum $\frac{1}{10}$mm. thick. With a 45min. exposure and a 7cm. spark coil, he found that the platinum alone was quite opaque. He experimented with 0·2mm. strips of lead, zinc, copper, amalgamated zinc, tin, steel, gold, silver, aluminium and platinum. Mercury 0·1mm. thick was as opaque as the platinum.

On p. 238 M. G. Moreau has a communication on "The Photography of Metallic Objects through Opaque Substances by Means of the Brush Discharge of an Induction Coil without a Crookes Tube." The discharge was produced by a coil, worked by a 6-ampere current, between a positive point and a small plate or one or more negative points. The sensitive plate, with the object to be photographed (a one millimetre thick aluminium wheel), were placed inside a completely closed cardboard box. The box could be placed at right angles or parallel to the discharge, and could be separated from it by cardboard or a wooden screen 0 005 mètre thick. No result was obtained with the discharge at right angles to the box. Six photographs with the discharge parallel gave absolutely clear, strong negatives. Two photographs taken through wood showed the existence of decided absorption of the rays and of the appreciable refraction. Exposure varied from half an hour to one hour. Up to the present no results have been obtained with the discharge from an electrostatic machine.

[6] This research was carried out in the laboratory of the École Normale, and in M. Pellat's laboratory at the Sorbonne.

In this connection the following letter appearing in the current issue of *Nature* is of great interest :—

"A brief account of some experiments which I have been making in my laboratory at Blythswood, in connection with the new photographic rays, may, I hope, be of interest to the readers of *Nature*.

"Three or four years ago I constructed a very powerful Wimshurst electrical machine It has 128 plates, three feet in diameter, and is driven by an electric motor of about 1½ horse-power. With this machine, which was specially built for quantity, I can obtain a torrent of sparks a foot and half or two feet long; and it occurred to me to try to obtain photographs, after the manner of Röntgen, but without the intervention of a vacuum tube."

"A thick sheet of lead was placed upright between the poles of the electric machine, as a screen, and was connected to the ground, the two poles being insulated. A sensitive dry plate was put into the camera dark slide, with a metallic object to be photographed (a steel washer with holes in it), and this was connected, by a wire which passed out of the dark slide to the ground. The whole was wrapped up in four folds of a black velvet focussing cloth, and was put in some cases between the negative pole and the lead screen and in other cases between the positive pole and the lead screen, the plane of the slide being perpendicular to the line of discharge. In all cases good strong negatives were obtained with exposures of about twenty minutes. The machine was arranged to give a silent brush discharge during the experiments.

"I next tried similar experiments with the dark slide containing the sensitive plate quite out of the line of discharge, and with the plane of the plate parallel to the line of discharge, and obtained equally good results. It seems, therefore, that the vacuum tube is not essential to the production of the Röntgen rays. With reference to this, however, I am not so sure, as I think I may have been deceived by using isochromatic plates—at all events I am engaged in further experiments either to confirm or the contrary. Blythswood.

"Blythswood, Renfrew, February 10th."

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

New York, *February 1, 1896.*

Acetylene Gas.—The only enlivening feature at present relating to electrical affairs is furnished by discussions concerning acetylene gas. The promoters of the Willson patent are apparently making desperate efforts to dispose of stock, going so far as to fill entire pages in the daily press with "reading articles" setting forth the revolution which the new gas will cause in illuminating methods. In the West central station owners are being urged by agents to purchase the local right of manufacturing the gas, the argument being that their present electrical plant can be utilised in the manufacture of calcic carbide instead of, as otherwise would be the case, becoming a total loss in a few months from the competition of acetylene gas. The official estimates place the cost of manufacturing one ton of calcic carbide at $20·72, based upon a cost of $10 for a yearly 24-hour horse-power delivered. At the works now being built at Niagara the Acetylene Company will have to pay $20 per annual horse-power, and since the illuminating value of acetylene, as determined by disinterested experimenters, has been found to be only eight times greater than that of ordinary coal gas, it follows that, on the basis of the Company's own estimate, the equivalent cost of manufacture of the new gas will thus be over 40 cents per thousand. In the States, the *cost* of coal gas delivered into gasometers is as low as 17 cents per thousand, or less than half that claimed for the new

Digitized by Google

competitor by its promotors. In order, apparently, to avoid application of figures showing the large cost of distribution under present methods, it is proposed to furnish the gas in cylinders, much stress being laid upon the advantages of this method. The programme includes even the displacement of petroleum, as it is stated that small cylinders for use with portable lamps will be furnished.

LEGAL INTELLIGENCE.

Gaskell and Another v. Gosling.

This case came before the Court of Appeal (consisting of the Master of the Rolls and Lords Justice Lopes and Rigby) on Wednesday, and was an appeal by the defendants in the action Gaskell and Grocott v. Francis and Cunliffe Gosling (reported in *The Electrician* of December 6th last) from a judgment of the Lord Chief Justice. The plaintiffs are makers of porcelain parts of electrical apparatus, and carry on business at Longport, Staffs., and brought their action to recover from the defendants, who are members of the banking firm of Gosling and Sharpe, £488. 9s. 3d., under the circumstances reported in our Dec. 6th issue. The action raised the all-important question as to whether trustees for debenture-holders who appointed a receiver to carry on the business of a company which was in liquidation were themselves liable to pay for goods sent into the receiver. The goods in question were so supplied, and when payment was asked for it was said that the goods were supplied to the Company, and that the Company must be looked to for payment. Down to 1892 Messrs. Poole and White (Limited) carried on business in Bread-street, and they also had a factory in Kentish Town. It appeared that they had become indebted to Messrs. Gosling and Sharpe to the amount of about £3,000, which was secured by a trust deed executed in favour of the defendants—two members of the firm, one of whom had died since the commencement of the action. On July 22, 1892, the trustees certified that the debenture holders' security was in peril, and thereupon the debenture holders appointed a man named Kelly as Receiver. On September 1st a petition was presented by a creditor to wind up the Company, under which, on September 14th, a compulsory order was made. After the winding up order the business was carried on by Kelly. In 1893 the plaintiffs called at the office and saw Kelly, and ascertained that the business was being carried on for the benefit of the debenture holders, and from time to time they took orders and supplied goods to Kelly in his capacity, as they alleged, of receiver. Three sets of debentures, amounting to £11,000, had been issued, the first being for £7,000, the second for £3,000 (those held by the defendants), and the third for £1,000. But Kelly being appointed, as above stated, on behalf of the second set of debenture holders, it was not until February, 1895, that the first debenture holders came in and turned him out. While Kelly was carrying on the business over £700 worth of goods were delivered to him by the plaintiffs; but by means of small credits that sum had been reduced to the amount claimed. The Lord Chief Justice in giving judgment, said that it was necessary for Kelly to obtain money or credit to carry on the business, and that when he was appointed Receiver he disclosed the fact that he was Receiver, and he held that the defendants were undisclosed principals, and he gave judgment for the plaintiffs for the amount claimed with costs.

Mr. JELF, Q.C., who appeared with Mr. Hamilton for the appellants (the defendants), contended that by the terms of the trust deed under or by virtue of which Kelly was appointed Receiver he was distinctly made the agent of the Company, and that even after the Company had gone into liquidation he was as personally liable as if he had had no principal behind him—as a Receiver appointed by the Court.

The MASTER of the ROLLS: He was appointed with authority to carry on the business.

Mr. JELF: Yes, but in doing so the defendants were simply exercising the power given them by the deed for the protection of their security, and by the terms of which deed the Receiver was made expressly the agent—as would be expected—of the Company. He had no business to pledge anybody's credit.

The MASTER of the ROLLS said that Kelly in point of law was the manager for the defendants.

Mr. JELF replied that the very object of the appointment was not to cast any present or future liabilities on the debenture holders, but to give them greater security.

The MASTER of the ROLLS: Could Kelly have disobeyed any orders given him by the trustees?

Mr. JELF: Yes, certainly; he was under no orders from the trustees.

The MASTER of the ROLLS: Could they have dismissed him at any moment?

Mr. JELF replied that the trustees had that power, as they could not be bound for ever to a man who turned out to be an unsatisfactory man.

The MASTER: If they directed him to give a certain order, and he disobeyed it, could they have dismissed him?

Mr. JELF: If they were not satisfied with the way he was going on, they had power to put somebody else in his place.

Mr. REED for the respondents argued that the decision to which the Lord Chief Justice had come was the right one, and ought to be upheld. He submitted that it was very difficult to see how a receiver, as such, could do what Kelly was authorised to do and did. A Receiver, as such, he contended, would only be Receiver of the mortgaged premises. The defendants had used the original term in the deed and called Kelly a Receiver, and proceeded to give him powers which no Receiver ever could have. The powers which Kelly had were incident to an agent for debenture holders—incident to a manager of a business, but not incident to a Receiver.

The MASTER of the ROLLS: The whole question seems to me to be whether the Trustees appointed Kelly as the Company's manager or whether they appointed him as their own.

The contentions of the parties having been further discussed,

LORD JUSTICE LOPES said there was evidence to show that Kelly was carrying on the business as receiver for somebody, because the form in which the goods were ordered where, so and so, "Kelly, Receiver," upon which Lord Justice Rigby remarked that he was carrying it on for the benefit of all whom it might concern, and not only for the trustees.

After counsel on both sides had briefly replied, their Lordships intimated that they would give judgment this (Friday) morning.

Clarke v. Julius Sax & Co., Limited.

In the Chancery Division, on Friday last, a motion was made on behalf of Messrs. Julius Sax & Co. to rectify the register of designs by striking off the registered design No. 206,807, registered by John C. Clarke, on the ground that it was not novel and that similar designs had been used before. The design consisted of a lamp used for an electric lamp to light shop windows, and was practically identical or similar to lamps used for this purpose before.

The motion was opposed on the ground that the design was novel, inasmuch as it had been adapted and applied to electric lights.

For the motion it was urged that the design of a lamp had been used for gas, and the fact that it was now used for electricity did not make it a novel lamp. Many similar lamps had been used for gas before, and it was impossible for the plaintiff to get protection because he had adapted the lamp to electricity, any more than if he removed the electricity and put in gas.

Mr. S. EADY, Q.C., for the plaintiff, said he had cross motion against the defendants for infringement.

It was arranged to treat both motions as one.

Mr. V. SMITH, Q.C., for Messrs. Sax, said that if his Lordship was against him on the motion to rectify, he should submit that his lamp was not an infringement, and that, looking at the lamps that were in the market at the time, it was not a fraudulent design or an imitation of the plaintiff's lamp.

Mr. EADY said that the plaintiff and the defendants were not strangers, as the latter had entered into an agreement with the plaintiff for the supply of certain lamps, and there was an action now pending in the Queen's Bench Division because the defendants had obtained lamps from somebody else in direct breach of the agreement.

Mr. Justice NORTH, in giving judgment, said that in his opinion both the motions failed. He could not say the plaintiff's design was so entirely without novelty that it ought not to be registered, and in his opinion the defendants were not infringing the plaintiff's rights in what they had done. The result was he must dismiss both motions, and there would be a set-off as to costs.—Judgment accordingly.

South v. Dadge and Co.

In the Westminster County Court, on Tuesday, an application was made to commit the defendants to Holloway for non-payment of a judgment debt. The principal point to be decided was who were the partners in the firm of Dadge and Co., electrical engineers, against whom judgment had been obtained. One of the defendants, Mr. Nelson Dadge, stated that at the time the goods were delivered the sole proprietor was his father (Mr. Charles Dadge) who was a retired farmer and knew nothing whatever about electrical work; he was the electrician, but at this time he was an infant. In May last his father sold the business to himself and Mr. W. A Fraser, but as witness was unable to find the necessary capital the partnership was dissolved. The business was now being carried on by Fraser, under the style of Dadge and Fraser. His Honour (Judge Lumley Smith) decided that the firm of Dadge and Co., was Charles Dadge, and pointed out that, even if Nelson Dadge was liable, he was an infant at the time the debt was contracted. He had no doubt the affair was a juggle, and plaintiff had been cheated out of his money. No order was made on the present application, but leave was given to amend the summons so as to be against Charles Dadge, trading as Dadge and Co.

South Staffordshire Tramways Company v. Ebbsmith & Wain.

An action was heard before the Lord Chief Justice on Wednesday, which was brought to recover damages from Mr. Joseph Ebbsmith and Mr. W. J. Carruthers Wain for alleged fraudulent conspiracy by which, while occupying a fiduciary position, they had induced the plaintiff Company to purchase from them certain unnecessary land and worthless patents; and also to recover secret profits and monies of the Company alleged to have been employed by the defendants in packing meetings of shareholders; and for the recission of the contracts for the purchase of the said land and patents. The defendants denied the allegations. An imposing array of counsel were engaged in the case, which occupied the whole of Wednesday, and was continued yesterday (Thursday). Much conflicting evidence was adduced.

Lazare Weiller and Co. v. Bolton and Sons.

The hearing of this action was resumed in the Queen's Bench Division on Friday last. Full particulars were given in our last issue, and Mr. Justice Mathew, in giving judgment, said he had come to the conclusion that there was no ground whatever for imputing to M. Weiller that he had made any misrepresentation to the defendants, and that the defendants were bound by the contract. As to the letter written by M. Weiller, that was a contract binding on the plaintiffs, and the defendants were entitled to counter claim in respect of it. The question of damages would stand over for further argument. He hoped the parties would come to some arrangement.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

SPECIAL NOTICE—The 1896 (fourteenth annual) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is NOW READY. The published price of the Directory and Handbook is 7s. 6d., post free 8s. 3d., abroad 9s. The book is greatly enlarged, is quite up-to-date, and includes the new Board of Trade Regulations issued February 6th.

NEW BOOKS AND EDITIONS.

The following New Books and Editions of "THE ELECTRICIAN" SERIES *can be obtained of the Booksellers or direct from the Publishing Offices :—*

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett *(now ready)*. Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"THE WORK OF HERTZ."—By Dr. O. J. Lodge, with many origina illustrations, price 2s. 6d. nett, is now ready.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

"ELECTRIC MOTIVE POWER."—A new work, by Mr. Albion T. Snell with this title, is now ready, containing the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d. post free (abroad 11s.).

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by Messrs. W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—By Mr. F. Marten Weymouth is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.), Prospectus on application.

"PRACTICAL NOTES FOR ELECTRICAL STUDENTS."—By Messrs. A. E. Kennelly and H. D. Wilkinson, price 6s. 6d., post free.

"THE ART OF ELECTROLYTIC SEPARATION OF METALS."—A second issue of Dr. Gore's book is now ready, price 10s. 6d. post free.

TENDERS INVITED.—The Vestry of the parish of St. Mary, Islington, invite tenders for the supply of electrical and engineering stores, manhole and other covers, castings, and other iron-work, &c. Tenders must be sent to Mr. Wm. F. Dewey, Vestry Clerk, Vestry Hall, Upper-street, N., by 12 o'clock on the 23rd inst.

——— The Corporation of Sunderland invite tenders for steam engines, continuous-current dynamos, water-tube boilers, fuel economiser, water-softening plant, and cast-iron tank. Specifications, &c., can be obtained at the office of the Borough Electrical Engineer, the Electric Supply Station, Sunderland, and tenders must be sent to Mr. Fras. M. Bowey, Town Clerk, not later than 5 p.m. on Friday, the 13th March. Further particulars are given in our advertisement columns.

——— The French Authorities require tenders for the supply of 125 tons of bronze or copper wire. Tenders to the Direction Générale des Postes et des Telegraphes, 103, Rue de Grenelle, Paris, by the 27th inst.

——— The Bridlington District Council require tenders for the lighting of the public streets for one year from March 31, 1896. Tenders to the clerk, Mr. C. Gray, Bridlington, by the 17th inst.

——— Tenders are being invited by the Cuckfield (Sussex) Board of Guardians for a telephonic installation at the workhouse premises.

TENDERS ACCEPTED.—The Corporation of Birkenhead have accepted the tender of Messrs. Drake and Gorham for wiring the Town Hall for the electric light. The amount of the tender was £215.

——— The Electric Lighting and Tramways Committee of the Blackpool Town Council have accepted the tender of the Lancaster Carriage and Railway Company for two new tramcars, and the tender of Messrs. Crompton and Co. for motors, exciters and fittings.

TENDERS ACCEPTED.—The Portsea Guardians received nine tenders for installing the electric light in the Hospital and Imbecile block. The tenders ranged from £174 to £305. It was decided to accept the lowest tender, that of Mr. T. H. Sotheby.

——— The Bradford Town Council have accepted the tender of Messrs. Siemens Bros. and Co. for the supply of two dynamos for the proposed new electricity works in Valley-road for £2,650, and the tender of Messrs. Willans and Robinson for the supply of two 600 I.H.P. steam engines for £4,400.

——— The Harrogate Town Council have accepted tenders for building work in connection with the erection of their electric lighting station. The whole of the accepted tenders amount to about £3,100.

TENDERS RECEIVED.—The St. Pancras Vestry received twenty-five tenders for wiring and fitting up the Vestry Hall and offices for the electric light, but at the last meeting of the Vestry it was stated that no authority had been given for the issuing of advertisements inviting these tenders, and therefore the question of the acceptance of a tender was deferred for the present, and the whole matter referred back to committee for reconsideration. The tenders received varied in amount from £304. 6s. 6d. (Messrs. Laing, Wharton and Down) to £553. 11s. 3d. (Maple and Co., Limited).

PARTNERSHIP.—Messrs. Fred. A. Donnison and Fred. Berlyn inform us that they have started business as electrical engineers, and will trade under the style of "Fred. A. Donnison, Berlyn and Co.," at 8, Great Portland-street, W.

BUSINESS CHANGE.—The business of patent agents and consulting engineers, which has hitherto been carried on the titles of Fell and Wilding and Fell and James respectively, will in future be carried on under the sole title of Fell and James.

MAN WANTED.—The authorities of the Hospital for Consumption, Brompton, require an experienced man to take charge of their electric lighting plant.

LIQUIDATION.—At a meeting of the proprietors of the Electric Novelty Syndicate (Limited), on January 13th, it was resolved to wind up the Company voluntarily. This resolution was confirmed at a meeting on January 27th, when Mr. G. F. Haskins, 18, Walbrook, E.C., was appointed liquidator.

BANKRUPTCIES.—The public examination of George Isaac Reekes, lately carrying on business as an electrical engineer at Shrewsbury, took place at the County Court, Shrewsbury, on Tuesday last. The bankrupt's liabilities amounted to £906. 11s. 11d., and the assets to £137. 0s. 4d. The debtor stated that in 1893 he was manager to the Worcester Electric Light Company, and in July of that year started in business on his own account. He had little or no capital of his own, but he had borrowed £380, and in addition he had received money from relatives who did not now claim from the estate. Altogether he had lost £1,026 in two and a-half years, and he attributed his losses to want of sufficient capital at starting and to loss upon some of his contracts. The examination was adjourned in order that the debtor might produce further accounts.

——— Notice is given that all claims against the estate of Philip C. Pope, late electrical engineer, 6, Castle-street, Hapton, near Burnley, must be sent in to the trustee, Mr. T. Edelston (Official Receiver), Preston, by the 20th inst.

——— At the Halifax Bankruptcy Court, on Tuesday, a Receiving Order was made against Charles Frederick Fox, electrical engineer and contractor, of 1, Bond-street, Leeds. The liabilities are estimated to amount to £460.

PRITCHETT ACCUMULATORS.—Mr. J. A. Newton, of Cromwell-buildings, Melbourne, has been appointed by Messrs. Pritchetts and Gold as sole agent for their accumulators for Australia.

THE "JOURNAL."—Part 119 is now ready of the *Journal* of the Institution of Electrical Engineers, containing Papers on "The Electric Wiring Question," by F. Bathurst, and "Concentric Wiring," by Sam Mavor, price 2s. 6d.

THE TELEGRAPH WIRE EXPORT TRADE.—The value of the exports of telegraph wire and apparatus from this country during the last month amounted to £57,224, as compared with £296,145 in December. The respective totals for January, 1895 and 1894, were £35,193 and £18,738.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.—The fourteenth annual issue of this publication is now ready. The new volume is very up-to-date, and even contains the revised Board of Trade Regulations issued last week. The Directorial Section of the work is equally forward, and will be found to contain corrections and new names and addresses complete up to the 5th of the current month.

CATALOGUE.—Messrs. H. M. Salmony and Co., of Charing Cross-road, W.C., forward us a copy of their 1896 catalogue. Particulars

Digitized by Google

and prices of a great variety of electric light fittings and apparatus are given, including switches, cut-outs and ceiling roses, cables and wires, wiremen's tools, jointing materials and accessories, the "H.M.S." measuring instruments, incandescent and arc lamps, lamp holders, sockets, dynamos and motors, electric bells and indicators, telephones, Leclanché cells, storage batteries, &c. Various tables are given, and the catalogue also includes a suitable index. Messrs. Salmony notify us that in consequence of the great demand for their instruments and accessories, they have been compelled to transfer the manufacture of accessories to separate works at Cheapside, Birmingham, where they have laid down extensive plant, which will enable them to execute orders with dispatch.

CATALOGUE.—We have received from Messrs. P. R. Jackson and Co., of the Salford Rolling Mills, Manchester, a copy of Section A catalogue and price list. This is well illustrated, and the views of the works, shops, yards and foundries which introduce the book show that Messrs. Jackson and Co. are in a position to execute orders for electrical and general engineering plant of any magnitude. The catalogue before us deals chiefly with machine-moulded tooth, spur and bevel wheels, steel roll pinions, fly-wheels, castings, pulleys, and a large assortment of patterns for steel boiler blocks. Messrs. Jackson and Co. claim to have made ten times as many machine-moulded tooth wheels as any other makers, and an important testimony to the care which is used in their manufacture is shown in a letter from the Engine, Boiler and Employer's Liability Assurance Company, Limited, in the annual report of which Company some time back reference was made to the number of breakdowns in tooth-gearing for main-driving. Messrs. Jackson and Co. received at the time the satisfactory assurance that none of the breakdowns referred to occurred to wheels made by their firm. The groups of steel castings which are given in the photographic illustrations accompanying the catalogue show in a very clear manner the great variety of articles of this class which are turned out by Messrs. Jackson and Co., and certainly justify the claim of the firm of occupying a foremost position in this branch of trade. A very useful set of tables of wheel patterns is given. The catalogue is most complete and handily arranged, and should be of special use to electric traction engineers and other users of geared electric motors. Messrs. Jackson and Co. have been particularly successful in their electrical department, and have large orders on hand, including eight dynamo machines of 270 kilowatts each.

ABERDEEN.—The Docks and Pilotage Sub-Committee, which was recently appointed to consider the question of the electric lighting of the harbour, before coming to a final decision in the matter have decided to obtain information from other ports where electric light has been introduced.

AMBLESIDE.—At the last meeting of the District Council the Electric Lighting Committee recommended the Council to oppose the application of the Windermere and District Electric Supply Company for a Provisional Order, and that the Council themselves apply for an order to supply electric current. The recommendations were agreed to.

BEDFORD.—At the last meeting of the Urban Sanitary Authority the Electric Light Committee reported that the work in connection with the public electric lighting was proceeding satisfactorily, and that they proposed to remove the gas standards in the area in which the electric lamps had been erected, and they therefore recommended that the arrangements in connection with the removal be left in their hands. Mr. Miller, in criticising this report, started by stating that he was not going to speak of his connection with the gas company, but he thought the order for the removal of the gas lamps should come from the Authority and not the Committee, and he complained that "since he had been shunted off the Committee he had not been able to get any information." Mr. Taylor said that the gas company had duly received six months' notice that they would not want the lamps after a certain date. Mr. Miller then argued that this notice only referred to the supply of gas light, and that it had no reference to the removal of the standards. After considerable discussion the report was approved. A letter was then read from Messrs. Sharman and Trethewy, on behalf of the gas company, complaining of the manner in which the electric light cables were being laid, and of their proximity to the gas mains. It was decided to ask the gas company to allow the Committee to take a tracing of their maps, showing the positions of the existing gas mains and other underground works, and to ask the Company to give three days' notice when the Company intended to dig up the ground on the electric light mains. The Committee further recommended that the Authority borrow £12,500 on account of the loan of £27,000 already sanctioned, for carrying out the following work:—For public lighting only, St. Mary's, St. John's and all the streets east of the Hitchen railway (£1,000) for private lighting only, Bromham-road, Union-street, Ashburnham-road (northern half), Goldington-road (to Bower-street), Rothsay-road and Gardens, De Parys-avenue (northern part), Park-avenue, Embankment (Newham-road to Bushmead-avenue), Kimbolton-road (to St. Agustine's-road) (£8,750); machinery at central station (£2,500), and contingencies (£250). Alderman Richards, in moving the adoption of the report, said that the private lighting in the first section had been provided for, and when all the plant was put in the lighting of that part of the town would be complete. With regard to the second section, the Committee thought that, as a matter of finance and expediency, there would be an advantage in preparing for the private lighting before that of the streets.

BLACKBURN.—At the last meeting of the Town Council the Gas Committee reported that they had considered the report of the Town Clerk upon the application of the Blackburn Corporation Tramways Company for sanction to work two sections of their lines by electricity instead of by horses and steam. It was resolved, on the recommendation of the Committee, to sanction the application of the Company subject to certain terms, and the Chairman of the Committee and Town Clerk were appointed to negotiate with the Company as to these terms.

BLYTH.—The following striking description of the position of electric lighting matters in Blyth is taken from the *Newcastle Leader*:—

"Those monuments to the stupidity of the Cowpen Local Board, the standards and overhead network of electric wires, still ornament the streets of Blyth. The usual order of things has been reversed by gas superseding electricity, and there are a number of complaints from those ratepayers who were previously accustomed to peruse penny novelettes at their bedroom windows by the aid of the electricity which was generated in Cowpen. Now, alack! the upper storeys and the tiles are plunged in a perpetual darkness, and the only reminder of the past magnificence of the lighting system is the unsightly entanglement of wires which stretches over the town in a manner indicative of the remains of a huge cobweb. The result is not picturesque, and, moreover, it is painfully suggestive of the folly of an Authority which imagined that, by placing the lights at a great altitude above the buildings, two streets might be sufficiently illuminated by one lamp. The idea was almost as brilliant as the light, but it didn't answer, and the councillors are objecting now to these unsightly pillars remaining to perpetuate the memory of their original lighting scheme. The contractor has, in consequence, been ordered to remove his plant."

BRADFORD.—At the meeting of the Town Council on Tuesday, the minutes of the Gas and Electricity Supply Committee, recommending the Council to make applications to the Local Government Board for power to borrow £40,000 for the extension of the electricity works, were agreed to.

BURTON.—At the last meeting of the Town Council Alderman Coxon, in moving the adoption of the minutes of the Farm Committee, said that they had instructed the surveyor to prepare plans for installing the electric light at the pumping station. The Committee were using a good deal of gas at the station, and, as they were anxious to be as economical as possible, they thought the electric light would prove to be cheaper.

CAMBERWELL (LONDON).—The Clerk reported at the last meeting of the Camberwell Guardians that during the past year 6,918,500 cubic ft. of gas had been consumed. This cost of this amounted to £766. 14s., and as this sum appears to the House Committee to be excessive, it was resolved to recommend that Messrs. W. H. Allen, Son and Co. be asked to report as to the probable cost of installing the electric light throughout the entire building, and as to the utilisation of the existing engine and boilers for supplying the necessary power. The matter was, however, referred back for further consideration.

CLACTON.—At the last meeting of the District Council a long debate took place on the lighting question. Dr. Murray proposed that advertisements be issued inviting proposals and estimates for lighting the streets electrically. At the present time he said they were paying 5s. per 1,000 for gas of an inferior quality, and the cost of the electric light would not in any event be more than this, and, in addition, they would have the advantage of a far superior light. After considerable discussion, the matter was referred to the Lighting Committee for consideration and report.

CORK.—A scheme for the construction of a system of electric tramways in the city and suburbs of Cork has just been brought forward, and plans of the suggested lines have already been lodged with the Clerk of the Union and the other public officers. The promoters intend to construct a series of lines to Blackpool, the Lower-road, St. Luke's, Western-road, and Douglas Village. It is also contemplated to make connections with the termini of the Great Southern and Western, the Cork and Bandon, the Cork and Macroom and the Cork and Passage Railway Companies. The plans have been prepared by Mr. Walsh, C.E., and Mr. Maurice Healy, M.P., is the solicitor to the promoters.

CHURCH LIGHTING.—Certain improvements are at present being effected at the Halifax Parish Church, and it is also contemplated to introduce the electric light.——The Wesley Chapel at Stow-Hall, Newport, was lighted electrically for the first time on Saturday last. About 150 incandescents are used, and the light has given the greatest satisfaction. Messrs. R. Alger and Sons were the contractors.

Digitized by Google

DOUGLAS (ISLE OF MAN).—Mr G. Gillmore writes, in reference to a Trade Note in our last issue, that we have scarcely done him justice in his opposition to the introduction of the electric light into Douglas; but Mr. Gillmore will see, on again reading the paragraph, that we expressly stated that his opposition was only as to its inopportuneness. Mr. Gillmore explains that the ratepayers are discussing the expenditure of considerable sums of money on urgent town improvements, and this, he considers, justifies opposition to the immediate introduction of the electric light; but, as we read Mr. Berry's contention, it is that the electric light is one of the urgent necessities of the town, in order that its popularity with visitors may continue. We took exception to Mr. Gillmore's contention that the cost of electricity is three times that of gas, and our reference to Mr. Trotter's report was in this connection. How far the opponents of the electric light can go is shown by the figures given at the end of last week's paragraph.

DUNGANNON (IRELAND).—At the last meeting of the Town Commissioners a letter was read from Mr. C. M. Wilson, intimating his intention of applying to the Board of Trade for authority to establish electricity works in the town, and asking for the consent of the Commissioners to his application. After some discussion it was decided to offer no objection to Mr. Wilson's proposals, and to give him every assistance and encouragement in his endeavour to introduce the electric light into the town, as the Commissioners think the scheme will lead to considerable reduction in taxation for lighting purposes, and will be a great advantage to private persons using artificial light and also in the better protection of employés in factories, workshops and shops.

FAREHAM.—At the last meeting of the District Council a letter was read from the Local Government Board with reference to the purchase by the Council of the undertaking of the Fareham Electric Lighting Company. The Board stated that they would be prepared to sanction a loan of £6,681 for a period of 20 years for the purchase, but would not entertain an application to borrow money for the purchase of additional land, for larger cables for underground lines, or for the payment of interest on the purchase money. The Board further stated that they would have to be satisfied that the Board of Trade approved of the purchase. The Chairman (Mr. T. Pankhurst) thought the communication a very satisfactory one, and that after a little further explanation the Local Government Board would sanction the borrowing of the additional £320. He therefore suggested that they should pay the £4,886 to the Company, obtain the new engine and anything else that might be required for putting the works in proper order, and engage a consulting engineer to advise and assist them in putting the affair on a sound footing. Resolutions to this effect were passed, and another inviting Mr. E. Manville to act as consulting engineer was approved. It is satisfactory that there is now a fair prospect of this very tedious dispute coming to an amicable termination.

GLASGOW.—The sub-committee recently appointed to visit Edinburgh and report on the electric lighting of that city has just issued its report. The sub-committee favourably compare the system of lighting in Edinburgh with that employed in Glasgow, and the report concludes with the statement that the sub-committee found that the street lighting of Edinburgh was much better than that of Glasgow, that that result had been obtained by a more judicious employment of the light, and recommend that the matter be remitted back to them to consider and report as to what measures are necessary to improve the present electric lighting system, with power to confer with the Electric Lighting Committee. They also strongly recommend that the Electric Lighting Committee of the Corporation appoint some of their members to co-operate with this Sub-Committee in further investigation.——At the last meeting of the City Council Mr. Primrose moved the adoption of the minutes of the Watching and Lighting Committee, which recommended the Council to adopt the report of the Sub-Committee. He said it seemed strange that, while every important city in the Kingdom was rapidly extending their electric lighting works, they in Glasgow should have been at an absolute stand-still for two or three years. This condition of affairs he attributed to the fact that the Lighting Committee had been endeavouring to avail themselves of the incandescent gas light, which was certainly an improvement on the ordinary gas light, and might serve in some streets for a time, but it was insignificant as compared with the electric light. It was not creditable to them that in a city like Edinburgh, with only about one-third of the population of Glasgow, 440 electric lamps should have been erected for street lighting, while at Glasgow they stood where they had been two years ago—viz., 120. The lamps in Prince's-street, Edinburgh, were run at 15 amperes, and the remainder were run some at 12½ and some at 10 amperes. At Edinburgh the cost was £20 per annum per lamp, and it was hoped that within a few months this charge would be reduced to £18 per lamp; in addition, the Glasgow Lighting Committee had to incur an initial capital expenditure of about £20 for their posts and lanterns, while these were provided free of cost at Edinburgh. Mr. Primrose further attributed the success of Edinburgh to the low charge at which the Council started to supply current, and to the fact that current for motor purposes was supplied at 3½d. per unit. Many printers had discarded their gas engines, and were working their presses by means of electric motors. Butchers, also, were utilising electricity for driving their chopping machines. Further, in order to give a fair and impartial trial to the merits of the electric light, the Edinburgh Council appointed a separate committee, which was free and uncontrolled by the Gas Committee; they had permission to enter into the heartiest rivalry with gas, and their aim was to cheapen what would unquestionably be the light of the future, and to make its use more general throughout the city. After a long discussion, in which Messrs. R. M. Mitchell, Dr. Colquhoun and Mr. Walter Paton took part, the recommendations of the Committee were adopted.

HALIFAX.—The Town Council have decided to oppose the Bill which is being promoted for the construction of a system of electric tramways in the town.

HAMMERSMITH (LONDON).—At the last meeting of the Vestry the Electric Lighting Committee reported that they had instructed the surveyor to invite tenders for the excavation, &c., work necessary in connection with the erection of the electricity generating station in the Fulham Palace-road, and they had accepted the tender of Mr. Greenham for carrying out this work. The Committee now recommend that the surveyor be instructed to prepare the necessary plans for the buildings, and this recommendation was, after some discussion, agreed to.

HORFIELD.—At the last meeting of the District Council, Mr. A. G. Stennard moved a resolution in favour of the appointment of a Committee to take into consideration the best means of lighting the district electrically. After a short discussion the resolution was agreed to.

HUDDERSFIELD.—The Local Government Board have sanctioned the borrowing of a further sum of £50,000 by the Town Council for the purpose of extending the electric lighting works. The loan is for a period of 25 years. The Council have already borrowed £50,000 for electric lighting purposes; £38,000 of this sum is to be repaid in 15 years and the balance in 30 years.

HULL.—Dr. Holder has just decided to resign his position as chairman of the Electric Lighting Committee. It is at least satisfactory to note that he has decided to take this step when the electric light undertaking of the Corporation is in a thoroughly sound financial condition, and no small share of the credit for the present highly satisfactory condition of the department is due to Dr. Holder.

KEIGHLEY.—At the last meeting of the Keighley and Bingley Joint Hospital Board the Buildings Committee reported that they had had the question of the electric lighting of the hospital premises under consideration. They had received various voluntary estimates for the work, and these ranged from £493 to £538. The Committee, however, recommended that no action be taken in the matter at present, and this recommendation was agreed to. It was decided to advertise for tenders for fitting up a system of telephones throughout the buildings.

LAMBETH (LONDON).—The electric lighting question was once more discussed at the last meeting of the Vestry. Letters were recently received from Mr. G. W. Sax and the County of London and Brush Provincial Company on the subject of the transfer of the Vestry's Provisional Electric Lighting Order. Mr. Martin, in opening the discussion, said he thought that the letters contained much more matter than the whole Vestry could go into, and he, therefore, moved that a special committee be appointed to consider the letters. This resolution was duly seconded, but Mr. King moved an amendment that the letters be referred to the Lighting Committee, and that two members be also appointed by each of the standing committees. This proposition was finally carried by 25 votes to 15.

LEEDS.—At the meeting of the Highways Committee on Wednesday, it was decided to recommend the Council to adopt the suggestion of the Tramways Committee to introduce the overhead system of electric traction throughout their entire tramway system. The Committee are to visit Bristol on Monday next in order to inspect the system in operation there.

LONDON COUNTY COUNCIL.—On the recommendation of the Building Act Committee, the London County Council have approved of the plans submitted with the application of Mr. W. B. Pinhey, on behalf of the Charing Cross and Strand Electricity Supply Corporation, for the construction of a generating station, coal bunkers, and furnace chimney shaft at 85, Commercial-road, Lambeth, and have authorised the erection of the station, bunkers and shaft.

MORECAMBE.—The District Council have at last come to terms with the Morecambe Electric Light and Power Company for the sale of the Company's business and plant. The Council have decided to pay the Company the sum of £3,897 for the undertaking.

Digitized by Google

OFFICE LIGHTING.—Mr. F. H. Taylor has just completed the work of wiring and fitting up for the electric light to the new premises of the Salvation Army Bank and General Insurance Office.

PRESTWICH.—At the meeting of the District Council, on Wednesday, the General Purposes Committee presented a report on the electric lighting question. The Committee state that the initial expenditure of an installation would amount to about £15,000, and, provided they had applications for about 6,000 lights, they thought there was every prospect of making a profit on the undertaking. They recommended the Council to make inquiries as to the number of lights that would be required before proceeding further in the matter. The report was adopted.

STAFFORD.—At the last meeting of the Town Council, the Chairman of the Gas and Electricity Committee, Alderman Peach, submitted the quarterly accounts for the Electricity Department. He stated that up to the present the customers had expressed themselves highly satisfied with the light and with the charges made. The engineer (Mr. J. F. Bell) estimated the revenue from the supply of current for the ensuing 12 months at £1,000, and then he believed they would make both ends meet and be able to pay their way without any charge on the rates.

ST. PANCRAS (LONDON).—The Vestry have decided to issue regulations for the information and guidance of electrical engineers and contractors carrying out work in the Vestry's area. At the last meeting of the Vestry the draft of these regulations was finally approved.

ST. SAVIOUR'S (LONDON).—At the last meeting of the Vestry the Works Committee reported that they had considered the letter from the County of London and Brush Provincial Company asking for the consent of the Board to their application for a Provisional Order. The Committee had informed the Company that they were opposed to the project, as two companies were already authorised to supply electric current in the district, and some inconvenience and great annoyance would be caused if a third company had power to break up the roads and pavements in Borough High-street. In consequence of these representations, the Company have agreed not to include the Borough High-street in their Order, and to limit the area of supply to the small portion of the district lying to the east of Bowling Green-lane, in Newcomen-street, the principal object of the Company being to connect the two districts of St. Olave's and St. George-the-Martyr, for which the Company had already obtained powers. Under these circumstances the Committee recommended that the formal sanction of the Board be given to the application, and this was agreed to.

SUNDERLAND.—At the last meeting of the Highways' Committee the Electric Lighting Sub-Committee presented their accounts for the half-year ending September 30th next. The Committee anticipate that the expenditure for the period will amount to £1,541. 2s. 9d., and the receipts to £960. 15s., leaving a deficiency of £580. 7s. 9d. The estimate was approved. The Committee also decided to join with the other Corporations in opposing an application by the owners of the patents of the three-wire system for an extension of time. Under this patent the Council at present pay a royalty of £50 a year.

SWANSEA.—At the meeting of the Electricity Committee on Monday last the Council's Bill for the purchase of the local tramways was considered. The Chairman pointed out that the Company were endeavouring to depart from the terms originally proposed by the Corporation and accepted by them. The amount to be paid to the Company (£32,000) was to be applied by them as follows: £10,400 in paying off the existing mortgage debt on the lines, and the balance in the purchase of motor cars for the working of the tramway system. The Company now, however, asked for the payment of this sum without any restrictions. In addition to certain other modifications, the Corporation agree to purchase the plant at the end of the term (21 years) at a valuation on condition that the plant is kept in proper repair to the satisfaction of the Borough Surveyor. The Town Clerk was directed to convey these terms to the Company, and in the event of their non-acceptance he was directed to withdraw the Bill. A special meeting of the Council has been convened for to-day (Friday) to confirm the action of the Committee.

TELEPHONE SUBSCRIBERS' LIST.—The National Telephone Company announce that a subscribers' list is in preparation which will contain the names, trades and addresses of all subscribers to the National Telephone Company's system throughout the country. It is calculated that this list will contain about 75,000 names, and that it will be ready for delivery to subscribers at the end of June next.

THE THREE-WIRE PATENT.—A conference of delegates from the Corporation of Glasgow, Edinburgh, Aberdeen, Belfast, Brighton, Bradford and Lancaster was held at the offices of Messrs. Martin and Leslie, of Abingdon-street, Westminster, on Monday, to determine what steps should be taken with reference to the royalty claimed by the Westinghouse Electric Company, who are the owners of the Hopkinson three-wire patent. It was unanimously decided to oppose the application for extension, and it was decided on counsel's advice that the Corporations of Aberdeen, Belfast and Edinburgh, who had not yet paid a royalty under the patent, should offer independent opposition to the application.

TORQUAY.—At their meeting to-day the Town Council will discuss Mr. W. H. Trentham's amended report on the electric lighting question. The Electric Lighting Committee recommend the Council to proceed with the scheme, and to erect the generating station at the Beacon Quay cellars. The estimated cost of the entire scheme is put at £22,300.

VIENNA.—The lighting contract of the Imperial Continental Gas Association expires in 1899, and the *Daily Chronicle* states that Dr. Friebeiss, the Imperial Commissioner who is conducting the affairs of the Municipality while the City Council remains dissolved, has been requested by the committee associated with him in the management to apply to the Diet for permission to raise a loan of 30,000,000 florins for the purpose of purchasing the works of the Association and erecting new gas and electric lighting works in the city.

WAKEFIELD.—The new County Council Offices at Wakefield are to be fitted up for the electric light. Current is to be supplied by the Wakefield Corporation.

WALSALL.—It has been decided to wire the new baths for the electric light at a cost of £120.

WANDSWORTH (LONDON).—At a meeting of the District Board of Works last week attention was called to the fact that a local tradesman had opened the streets, laid an electric cable, and supplied current to private consumers without having received the sanction of the Board. A letter had been received from the County of London and Brush Provincial Company calling attention to this matter, and pointing out that they were the only persons having Parliamentary powers for opening the streets to lay electric mains, and that should any accident occur with the installation put down by Mr. Singer, they would probably be blamed. A discussion arose, and many of the speakers showed an inclination to support the application of Mr. Singer that the cable he had laid down should remain, and that he should have permission to put down a second cable. An amendment, however, that the matter should be referred back to the General Purposes Committee was finally adopted.

WATERLOO-WITH-SEAFORTH.—The District Council have decided to offer no objection to the application of the Liverpool District Lighting Company to the Board of Trade for a Provisional Order for the district.

WIMBLEDON.—The electric lighting licence of the District Council expires in July next, and recently application was made to the Board of Trade for an extension of time in order to enable the Council to apply for a Provisional Order. This extension has just been granted by the Board of Trade.

WORCESTER.—At the last meeting of the City Council, on the motion of Alderman Williamson, the Chairman of the Electricity Committee, the Council decided to borrow a further sum of £5,000 for electric lighting purposes

YORK.—At the general meeting of the shareholders of the York United Gas Light Company (Limited), last week, the Chairman (Mr. J. F. Taylor), in alluding to the subject of the electric light, said he had not usually alluded in his speeches to what some odd members of the public were apt to magnify as the light of the future—viz., the electric light. On the present occasion he would, however, do so. He then went on to quote some remarks of Prof. V. B. Lewes about the incandescent gas light. Mr. Taylor then told his hearers that, by using the best form of incandescent burner, light for light, the York gas might safely be said to be from 12 to 15 times cheaper than the electric light at its prevailing cost. The price of gas at York is from 2s. to 2s. 2d. per thousand, and it would be very interesting to know how Mr. Taylor arrives at his figures. It may be safely assumed that the speaker has not heard of Mr. A. P. Trotter's report on the comparative price of the electric light and gas recently prepared for the Hastings and St. Leonards-on-Sea Electric Light Company, or he would have been more guarded in his assertions. Mr. Taylor's previous forbearance towards the electric light may be accounted for by the fact that, though the York City Council have been for some time past talking of introducing the electric light, up till quite recently no very serious steps have been taken in the matter. Prof. A. B. W. Kennedy has now, however, been appointed consulting engineer to the Council, and doubtless Mr. Taylor has been reading the results of the Professor's connection with the Councils of Edinburgh and other cities, where very successful electric lighting works have been erected. Our readers will remember that at the last meeting of the Edinburgh Gas Company, the Chairman admitted that the electric light competition affected them in a very marked degree, and he issued an *ad misericordiam* appeal to the residents of Leith to come to the Gas Company's rescue. Mr. Taylor is perhaps fearsome of a similar result at York.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

January 23, 1896.

1,611. W. McGEOCH, JUN. Glasgow. Improvements in and relating to holders for incandescent lamps.*

1,669. W. TURNER. London. Improvements in or relating to electric batteries.

1,678. W. DIGBY. London. Improvements in electrodes for electrolytical purposes. (A. E. Woolf, United States.)

January 24, 1896.

1,685. T. COOPER. Walsall. Method of utilising primary induced currents of dynamo-electric machinery.

1,687. H. RUDOLF. London. Isolator for fastening electric conducting wires.*

1,695. T. MEACOCK. Birmingham. Improvements in connection with electric tramways.

1,744. D. KORDA. London. Improvements in electric traction.*

1,775. A. I. GRAVIER. London. Improvements in dynamo machines.

January 25, 1896.

1,793. J. M. INGLIS. Edinburgh. The Inglis electrical photographic lamp for studio purposes.

1,796. W. G. MULLINER and W. H. STURGE. Birmingham. Improvements in means for or connected with the charging of portable electric secondary batteries or accumulators.

1,838. H. W. C. COX and G. BOWMAN. London. Improvements in electrically-driven wool shearing or hair-clipping machines.

1,842. T. R. D. KENNY. London. Improvements in holders for electric glow lamps and analogous electrical contact devices.

1,843. D. URQUHART and F. WYNNE. London. Improvements in the means and apparatus for connecting electrically-propelled vehicles on tram and railways to fixed conductors.

SPECIFICATIONS PUBLISHED.

NOTE.—All Specifications can now be obtained at the uniform price of 8d. each.

1895.

684. CANNON. Incandescent electric lamps.

687. CHEFFEY, JAMES and WARD. Generating or transforming electric currents.

2,277. HIRCHMANN. Electric accumulators.

4,466. PATERSON and HILL. Search-light projectors.

5,956. PEARSON. Thermometric circuit closers.

15,787. BRAHAM. Electroliers, electric light standards, &c.

22,985. BREMER. Transmitting electric currents.

COMPANIES' MEETINGS AND REPORTS.

Cuba Submarine Telegraph Company (Limited).

The forty-ninth ordinary general meeting of this Company was held on Wednesday at the offices of the Company, 58, Old Broad-street, Mr. Charles W. Parish (Chairman) presiding.

The SECRETARY (Mr. James Scott) read the notice calling the meeting.

The CHAIRMAN: Gentlemen, I presume you will wish to consider the report as read. If you will allow me I will follow our usual custom and point out to you any important variations there may be in the accounts for the past six months as compared with the same period of 1894. As far as expenses are concerned we have an amount of £6,084 in the half-year now under review, as against £5,633 in 1894, an apparent increase of £451; but an item of £545 spent upon a new harbour length at Cienfuegos and other repairs more than accounts for this amount. The salaries and wages paid at the stations have risen from £2,018 to £2,165 on account of overtime necessary to meet the increased business. There is also an addition of £72 for travelling expenses; but, *per contra*, there is a reduction from £829 for maintenance of land lines to £532; so the total expenses of the stations come out at £3,000, as against £3,064 last year. The traffic receipts have increased from £19,088 to £23,934, which is a very large proportion, but you will please understand that it is due to the disturbed state of the island owing to the revolution, which still continues. After paying dividends at the rate of 8 per cent. per annum on our Ordinary shares and 10 per cent. on the Preference, you will notice we are able to place £10,000 to the reserve fund and carry forward £3,539 to the new account. This substantial increase to our reserve fund is most necessary, for we have to meet a heavy expense in connection with the new cable referred to in paragraph 6 of the report. To more clearly explain the position I would draw your attention to the chart hanging before you; you will notice the town of Manzanillo, and you will understand that the suggestion which the Spanish Government made to us was to connect this town by a cable to one of our existing lines running from Santiago to Cienfuegos; but these cables have been laid for so many years that we could not take the risk of disturbing them. Then followed long and difficult negotiations carried on partly with the authorities in Cuba, and then at Madrid, where Mr. Keith and Mr. Scott went to be in actual touch with the Government. These negotiations finally led to the Spanish Government granting us a subsidy of £2,000 per annum to lay and work a cable between Cienfuegos, Casilda, Tunas, Jucaro, Santa Cruz, and Manzanillo. This cable was successfully laid and duly received from the contractors by Mr. Keith, acting on behalf of the Company, and we have since received the thanks of the Spanish Government for having carried out the work so promptly. This cable has entailed our opening five new stations, which will increase our expenses accordingly; but, on the other hand, we hope a satisfactory traffic will gradually develop over and beyond the Government business. You will notice that it can be continued from Manzanillo to Santiago, if necessary, as mentioned in the report. Before I close my remarks I would like to mention the very valuable services the Company has received from Mr. Keith; he has just returned from Cuba, and reports that our cables and property are in satisfactory order. His special acquaintance with the local circumstances has been of great advantage to us. I would also like to bear witness to the excellent manner in which our Secretary has met the increase of work which has lately fallen upon him. Gentlemen, our next meeting will be our fiftieth, and I hope we may then meet you with the same satisfaction as we do to-day. I will now formally move—

"*That the report and accounts for the half-year ended December 31st last, now submitted, be received and adopted.*"

Mr. GEORGE KEITH seconded the resolution.

Questions relating to the new cable, as to the increased traffic likely to result therefrom, and especially as to the subsidy from the Spanish authorities, were put by several speakers, and Mr. DEARBERG called attention to the large amount placed to the credit of the reserve fund.

The CHAIRMAN, in reply, said: I have much pleasure in answering the various questions put to me. The matter of the new cable was to a great degree one of expediency. In the first place, the Spanish Government were determined to have a cable, and if we had not laid it they would have laid it themselves. In the second place, they give us a subsidy and pay half-rates for their messages. It was part of the original concession that they should do so, and I need only indicate to you the large increase in the receipts you have seen for the last two half-years to show how much that amounts to. Then, as to the amount we place to the reserve fund, I would have you remember that some of our cables have been down for a long time, and we should be to blame if we did not greatly increase our reserve fund to meet any casualties that may occur.

Mr. DEARBERG, intervening, observed that he did not complain of building up a reserve. What he complained of was that they put more to reserve than they paid in dividends.

The CHAIRMAN: I understand that, and on the whole I think it is rather pleasant for Directors to be scolded for not paying out more in dividends, because we are shareholders, and we should like to have large dividends as well as anybody else. It is because we know the details of the business that we feel we should not be justified in paying larger dividends. I warned you at the last meeting that it was probable we might have to reduce our rates, and we felt the large increase of business we had had was not due to any general expansion of business on the island of Cuba, but to quite exceptional causes, which might come to an end at any time. With regard to our deposit at the New English Bank of the River Plate, we have made a careful calculation, and we believe that the £8,000 in reserve will more than cover any loss that may accrue.

The resolution was then carried unanimously.

The CHAIRMAN then moved the following resolution:

"*That the following dividends for the half-year be now declared upon the shares of the Company, viz., at the rate of 10 per cent. per annum, subject to income tax, on the Preference shares, and 8 per cent. per annum, free of income tax, on the Ordinary shares, payable on and after to-morrow.*"

Mr. R. KAYE GRAY seconded the resolution, which was agreed to unanimously.

A cordial vote of thanks to the Directors concluded the proceedings.

Anglo-American Telegraph Company (Limited).

The ordinary general half-yearly meeting of this Company was held on Friday at Winchester House, the Marquis of Tweeddale (Chairman) presiding.

The notice calling the meeting having been read,

The CHAIRMAN said: Gentlemen, the report now before you is the best we have been able to present to you since 1892. In the half-year ended December 31, 1892, we paid you a dividend of £1. 10s. per cent., in 1893 it fell to £1. 6s. per cent., in 1894 to £1. 3s. per cent., while for the past half-year we are able to recommend you a dividend at the rate of £1. 8s. per cent., of which 10s. has been paid already, leaving a balance to be paid of 18s. The increased dividend is due, first, to improved traffic; secondly, to an increase in our receipts from the steamship "Minia," and, thirdly, to a considerable reduction in expenses. The increase in traffic amounted to £15,764, the result, of course, of the great improvement which has taken place in commerce and business, an improvement which I hope is destined to continue. The "Minia" has earned for us £1,350 more than last year, and we are able to report a decrease in the expenses of £1,056. This decrease in expenses is satisfactory, inasmuch as it compares with a half-year in which the decrease was no less than £3,399. I have before me a comparative statement of working expenses from the half-year ending December, 1891, and it shows a steady decrease from year to year to the present time, aggregating as much as £8,712. Our renewal fund now stands at the respectable figure of £624,265, and the value of the securities at the close of the half-year exhibited an increase of £74,000. In connection with the renewal fund, I may mention that owing to the lease of our offices in Throgmorton-street coming to a termination, we have

Digitized by Google

purchased the lease of very suitable offices in Old Broad-street. The cost of this new lease, which is for 13 years, is £28,541. The offices are very superior to those we had before, and I am glad to say that with the receipts obtained from letting off a certain portion of the building the cost to us is within a pound or two of what the offices were which we have relinquished. The condition of our cables is very satisfactory. It is true that during the half-year we have not been altogether free from interruption, but with the exception of the 1873 cable, which was interrupted in the preceding half-year, and repaired on July 16th, the interruptions have been confined to our short cables west of Newfoundland and to the cable in the shallow sea. The repairs to these cables have been executed with skill and promptitude always exhibited by our officials both on the ship "Minia," commanded by Capt. Trott, and by our local officials at St. Pierre, who, in face of great difficulty from the weather and otherwise, repaired one of our most important short cables with perfect success. The report refers to the French case, and that, I am sorry to say, is not any nearer, or very little nearer, settlement than it was when I last addressed you. I need hardly say that it is not from any want of energy on our part, but the French lawyers, not unlike our own, were not disposed to be in too great a hurry in the settlement of such matters. The present position is this: the French counsel have had the matter in hand for many months, and it is understood that the Company's case is in draft, but not settled. When it is settled it will be proceeded with before the proper Court, and I hope that when we next meet I shall be able to report some settlement. I am glad to be able to inform you that the new half-year has commenced in a manner which augurs very well for our meeting six months hence. With these observations I beg to move that the report and accounts be adopted, and the dividends set out therein be approved.

Mr. FRANCIS A. BEVAN (Deputy-Chairman) seconded the resolution.

Mr. GARNER asked if the Board could say when the renewal fund would have reached a sum which might be considered sufficient. In his opinion they did not require the £1,000,000 that was at one time suggested necessary.

The short discussion which arose referred almost entirely to the delay in the settlement of the French action, and questions as to the amount of costs already incurred by the Anglo Company in the matter, were put by several shareholders.

The CHAIRMAN, in reply, said: I have been asked, with regard to the renewal fund, when we are going to stop adding to it. It is far too early in the day to give any definite answer to that question. Our renewal fund is now worth about £670,000, but our cables are getting older every day, and when they were much younger we considered £1,000,000 would be barely sufficient to make us feel quite confident of being able to keep our four cables in proper condition. Then Mr. Wood asked if our cables were in working order. Well, of course, the French cable is not, but all the others are in good condition. We have no present intention of repairing the French cable. Mr. Griffith, as I understood him, complained of the delay that had taken place in the settlement of the French case. Well, there is an old saying that "you may lead a horse to the water, but you cannot make him drink." In the same way you may do what you can—our legal advisers here and on the other side do what they can—but we cannot force this case on the Court of Appeal any quicker than they are willing to take it. There is no delay on our part. I must say distinctly that we on this side of the table do not anticipate any very large result from this case. The French Cable Company is not in a very good condition, and I do not believe they would be able to pay any large damages; but in any case we do not expect to get any very substantial sum. If we do, we shall be only too pleased, but our present opinion is that it would not do to rely on any large sum being awarded for damages.

Mr. FRY asked when the Board formed the opinion that the amount the Company were likely to receive would be a small one. If he referred back to the old reports he found the prospect of the damages running into thousands and tens of thousands of pounds was held out to them.

The CHAIRMAN: When I spoke of the possibility of our receiving considerable damages the decision from which we are now appealing had not been given.

Mr. C. BURT hoped the shareholders would not press the discussion further. Every word spoken here against their interests would be carried to the other side and made use of against them. There was no doubt but that the first decision was greatly in their favour, and if it could have been carried out the Company would have received a very large sum. But from that decision appeals were carried from court to court, until now they were at the last appeal on a question of law. Surely, having gone so far, and paid, as he believed, almost every item of costs they had to pay to the present time, it was not worth their while to make this fuss and say they would not have the case finished. He felt sure that after waiting for so many years to get justice done them they would go on until they obtained a final decision.

After further discussion the resolution was agreed to unanimously.

The retiring Directors (Mr. Francis A. Bevan and Mr. W. S. Cunard) were re-elected.

Mr. GRIFFITH moved the re-appointment of the auditors, Mr. Joshua Dean and Mr. John Gane, F.C.A.

Mr. GARNER seconded, and the motion was agreed to.

The proceedings terminated with a vote of thanks to the Chairman.

Liverpool Overhead Railway Company.

The half-yearly meeting of the shareholders of this Company was held on Tuesday last at the Law Association Rooms, Liverpool, Sir W. B. Forwood presiding.

The CHAIRMAN, in moving the adoption of the report and accounts, said that the passenger traffic had increased during the past half-year by 140,000. There was, however, a decrease in workmen's special tickets of 90,000, which was accounted for by the fact that at the end of 1894 they gave up the 2d. return workmen's tickets. At first this step led to a large decrease in the number of workmen who used the early morning trains, but they were gradually coming back to the railway. The total number of passengers carried during the half-year was 3,780,000, the total for the year being 7¼ millions. Their gross revenue had been £31,590, showing an increase over the corresponding half-year of £5,916. They had therefore earned 1·97d. per passenger as against 1·67d. Their working expenses amounted to £18,893, an increase of £1,731, and the trains had travelled 7,000 more miles. Their working expenses as compared with revenue had been 60 per cent., against 67 per cent. in the same period of last year. After paying £2,500 interest on debentures, they had a balance of £10,196, which, with the balance brought forward of £1,302, left £11,499 available for dividend. The usual dividend of 5 per cent. on the Preference shares would require £2,600, and the Directors recommend the appropriation of £6,825 to the payment of a dividend of 3½ per cent. on the Ordinary shares, as against 2 per cent. for the same period last year. This would enable them to carry forward £2,074, as compared with £1,087. The chairman stated that considerably more money had been spent upon maintenance of way works, repairs, &c. That had been done in order to keep the railway in the best possible condition. The amount they had set aside for the renewal of boilers and machinery (£1,200) was rather more than in previous half-years, and they had started a contingent fund towards which they had carried £100. The Chairman then referred to the progress being made with the southern extension, and they hoped that part of the line would be opened in the month of August. They proposed to transfer the station from the extreme end of the Herculaneum Dock to the bottom of the footbridge over the Cheshire Lines Railway. That would be much more convenient to the artisans using the docks, and would be more accessible to the large population residing in that portion of Toxteth-park. The new station would be at the Dingle, in close proximity to the ancient chapel of Toxteth Park, and he thought that that part of the line would prove a valuable feeder to their general system. The line had been maintained in a thoroughly efficient condition during the past year. No less than 98·40 per cent. of their trains had been on time, and that showed not only that they had worked their system with great punctuality, but that there had been no breakdowns. A great deal of their success was due to their manager, Mr. S. B. Cottrell, and the members of his staff, who had given them the most loyal service, and showed great industry and watchfulness in looking after the concern. He was glad to say that they received no complaints from the public, a circumstance which proved that they were not only a great public convenience, but were doing their work well.—The motion was duly seconded and carried.—The retiring Director (Mr. H. Brocklebank) and the auditors were re-elected, and the usual vote of thanks brought the proceedings to a close.

Newcastle and District Electric Lighting Company (Limited).

The ninth ordinary general meeting of this Company was held on Tuesday at the Station Hotel, Newcastle-on-Tyne. The Chairman (Mr. John D. Milburn), moved the adoption of the following report:—"The supply of current continues to give satisfaction to the Company's consumers. The installations to the Company's mains during the year are equal to 3,200 10 c.p. lamps, bringing the total up to about 24,700; 471,662 units of electrical energy have been supplied, against 431,239 in 1894. 1,650 yards of main and branch piping have been added, together with 3,781 yards of main and branch cable. The condensing plant continues to work satisfactorily, and the Directors anticipate making other improvements with the object of still further reducing the cost of production. The gross earnings during the year amount to £4,302. 9s. 11d., and after paying interest, making provision for depreciation, and writing off the balance of formation expenses (£563) a dividend is recommended at the rate of 4 per cent. for the half-year ended December 31st (less income tax), making 6½ per cent. for the year." He said it was gratifying to be able to state that their output was still on the increase. They had issued no new shares because they had required no extra money. They were keeping up a depreciation fund; they were fully alive to its value, and intended to continue it. A dividend at the rate of 4 per cent. for the half-year ended December 31st, making 6½ per cent. for the year, was then declared. The retiring directors, Sir B. C. Browne and Col. H. S. Dyer, were re-elected, as were the auditors, Messrs. Strachan and Co.

Cambridge Electric Light Company (Limited).

The annual meeting of the shareholders of this Company was held on Friday last at the offices, Thompson's-lane, Cambridge. The CHAIRMAN (Mr. D. Munsey) in moving the adoption of the report and accounts, said that although they had made an extra profit and had generated more units than in 1894, their consumption of coal was about the same. This had been mainly brought about by the new sub-stations which had been constructed. The motion was seconded and duly passed.

The CHAIRMAN then referred to the fact that the Company had debentures to the amount of £3,000 or £4,000, and after they had paid their debts they would owe the bank £5,000 or £6,000. If the Directors issued any new shares the present shareholders would have the opportunity of taking them up *pro rata*, according to their holding.—A discussion also arose on the public lighting question. It was stated that the contract with the gas company would shortly expire, and a shareholder expressed the opinion that the Company ought to make an effort to secure the contract.—The Chairman, in reply, stated that the Corporation had already authorised them to erect four arc lamps on the Market Hill as an experiment.—The retiring Directors, Mr. W. C. Hall and J. B. Simpson, were re-elected, as was also the auditor, Mr. A. Rutter,

Digitized by Google

City of London Electric Lighting Company (Limited).

The report of the Directors of this Company, to be presented to the shareholders at the meeting to be held at Winchester House, London, E,C., on Friday next at 2:30 p.m. is as follows:—

Capital.—The expenditure on capital account during the year ended December 31st last amounted to £138,456. 2s. 6d. The balance of £100,000 of the present authorised amount of £400,000 Five per Cent. Debenture Stock has been issued, and an official quotation granted by the Committee of the Stock Exchange.

Revenue.—The total revenue for the year was £109,766. 19s. 10d., from which £50,666. 13s. 11d. has to be deducted, leaving a net revenue of £59,100. 5s. 11d., which, with £752. 13s. 11d. brought forward, makes a total available sum of £59,852. 19s. 10d., of which £12,076. 16s. has been distributed in interest on Debenture stock for the year, and £12,000 in interim dividend on £400,000 Six per Cent. Preference shares for the half-year to June 30th last, leaving for further distribution £35,766. 3s. 10d.

The Directors recommend dividends of 6s. per share on the Preference shares for the second half-year, making a total distribution of 12s. per share or 6 per cent. for the year, and 10s. per share on the Ordinary shares, being at the rate of 5 per cent. per annum. This will absorb £32,000, leaving a balance of £3,776. 3s. 10d. to carry forward. The necessary provision for depreciation in accordance with the City of London Electric Lighting Act, 1893, has been made.

The generation and distribution expenses for the year, including repairs and renewals, were 36·87 per cent. of the earnings, as compared with 46 for 1894 and 54·2 for 1893. The Company continues to make satisfactory progress, as will be seen by the following comparative statements, showing the position of the Company with regard to its earning powers as it was in 1892 and at subsequent periods:—

Number of Customers and Lamps Connected.

	Dec. 31, 1892.	Dec. 31, 1893.	Dec. 31, 1894.	Dec. 31. 1895.
Number of customers being supplied	242 ...	1,080 ...	2,740 ...	4,230
Number (equivalent) of 8 c.p. lamps connected	20,241 ...	65,341 ...	135,460 ...	195,317

On February 5, 1896, there were 201,126 8 c.p. lamps (equivalent) connected, and in addition 8,759 awaiting connection. In September last Mr. Joseph Bevan Braithwaite, Jun., resigned his seat on the Board, and two of the Directors (Lord Suffolk and Mr. F. W. Reynolds) now retire and offer themselves for re-election, as do the auditors (Messrs. W. H. Pannell and Co.).

National Telephone Company (Limited).

The report of the Directors of this Company for the half-year ended December 31st last, to be presented to the shareholders at the meeting to be held at the Cannon-street Hotel, London, on Thursday next at 1 o'clock, states that the income amounts to £422,649. 6s. 9d., compared with £378,789. 4s. for the corresponding period of 1894, an increase of £43,860. 2s. 9d. The working expenses amount to £216,537. 0s. 5d., compared with £205,192. 12s. 10d. for 1894, an increase of £11,344. 7s. 7d. The net result for the half-year's working (after deducting Post Office royalties amounting to £38,238 12s. 1d.) is a profit balance of £167,873 14s. 3d., against £138,642. 14s. 6d. for 1894, or an increase of £29,230. 19s. 9d. Out of the available balance of £138,217. 3s. 11d. the Board recommend a dividend at the rate of 6 per cent. per annum, less income tax, on the first and second Preference shares, 5 per cent. per annum, less income tax, on the third Preference shares, and 6 per cent. per annum, free of income tax, on the Ordinary shares, to transfer £35,000 to the reserve fund, and to carry forward the balance of £6,623. 7s. 11d.

The report for the half-year ended June 30, 1895, contained the following paragraph:—

"The draft of the formal agreement with the Post Office, for the acquisition by the Department of the Company's trunk lines, having been laid upon the table of the House of Commons in accordance with the promise of the Postmaster-General, the preliminary agreement requisite to give effect to the arrangements was duly executed and completed on March 15th last. The difficult and somewhat complicated details connected with the transfer of the Company's trunk lines are approaching completion, and payment of the purchase money, now in process of being ascertained, may be expected shortly."

In respect to the reference made in the report of the Directors for the period to June 30th last as to the Company's trunk lines being taken over by the Post Office, the many difficult questions involved in the settlement have led to some further delay. The amount due to the Company is now practically agreed, and there is reason to believe it will very soon be paid. In the meantime the Board are loyally co-operating with the Post Office in preparing for that transition in the conduct of the trunk business of the country which will follow the assumption of the trunk lines by the State.

Kensington and Knightsbridge Electric Lighting Company (Limited).

The report of the Directors of this Company for the year 1895, to be presented at the ninth ordinary general meeting, to be held at 1, Great George-street, Westminster, on Thursday next, at 5 p.m., states that the mains, which extended to a length of 18¾ miles on December 31, 1894, have been increased during the year 1895 to 20 miles, and that during the year the number of houses and shops connected with the system has increased from 908 to 1,109, while the number of lamps calculated on the usual basis of 8 c.p. has increased from 80,678 to 94,780.

The Debenture debt of the Company has been converted from Four and a-Half per Cent. First Mortgage Debentures to Four per Cent. Debenture Stock. The debentures were paid off at £105 by new stock issued to the holders. Further issues of Debenture Stock have since been made, £6,800 at £103, and £15,755 at £105 per cent., of which amount £11,780. 15s. 0d. was paid by December 31st. The Directors have thought it advisable to appropriate the balance of premiums thus obtained, after deducting the expenses of creation and issue of this stock, to the reduction of the cost of conversion, and have written £1,000 off the goodwill account and strengthened the renewal account by transferring to it £4,270. 2s. 11d., making the total amount placed to that account £9,990. 13s. 8d. After providing for the above amounts, and paying the dividends on the Six per Cent. First Preference shares to June 30, 1895, on the Five per Cent. Second Preference shares to September 30, 1895, and an interim dividend at the rate of 5 per cent. per annum on the Ordinary shares for the first half of the year, the balance standing to the credit of the nett revenue account for the past year is £5,227. 7s. 6d. Of this sum £1,450 has been appropriated to the payment of the First Preference dividend to the end of the year, and £150 has to be set aside to meet the portion of the dividend on the Second Preference shares accrued to the same date, leaving £3,627. 7s. 6d., out of which it is proposed to pay a further dividend on the Ordinary shares at the rate of 7 per cent. per annum for the past half-year, making, with the interim dividend paid to June 30th, 6 per cent. for the year. This will leave a balance of £1,089. 17s. 6d. No provision has been made in the accounts for Directors' remuneration.

Mr. Granville R. Ryder and Mr. Alfred Sohier Bolton offer themselves for re-election as Directors, as do the auditors, Messrs. Lovelock, H. W. S. Whiffin and Dickinson.

Bristol Tramways and Carriage Company (Limited).

The report of the Directors of this Company states that the gross receipts for the half-year amounted to £51,664. 17s. 9d., and the working and general expenses and renewals to £40,210. 9s. 11d., leaving a balance of £11,454. 7s. 10d., which it is proposed to appropriate as follows:—Interest on Four per Cent. Mortgage Debenture Stock, £1,378. 13s. 6d.; dividend at the rate of 6 per cent. per annum (to be paid on the 28th inst.) for the half-year ended December 31st, £7,350. A balance of £2,725. 14s. 4d. (including £200 for leased premises redemption, £1,000 for permanent way renewals, and £525. 14s. 4d. for electrical renewals) has been carried to reserve and renewal funds. The receipts from the tramways department show an increase of £4,271. The total number of passengers carried during the past six months on the Company's cars and omnibuses was 7,798,952. The Company's City and Kingswood Electric Tramway was formally opened on October 14th last, under favourable auspices, the public ceremony being attended by many distinguished scientific men, as well as the members of the Corporation and other local authorities. The Directors state that the working of the City and Kingswood electric tramway since the opening in October last has been most satisfactory, and the public greatly appreciate the immense advantage of a service so superior to that of the horse cars. For the four months during which the line has been opened the number of passengers carried has exceeded 1,000,000. Pursuant to an agreement with the Corporation the Company have applied to the Board of Trade for a Provisional Order to confirm the construction of the new lines in the vicinity of the tramways centre and St. Augustine's Bridge, and the Directors have included in the Order clauses enabling the Corporation and local authorities to approve of the use of electricity on other portions of the Company's existing system.

The retiring Director (Mr. Joseph Wethered) and the auditor (Mr. Solomon Hare) offer themselves for re election.

India Rubber, Gutta Percha, and Telegraph Works Company (Limited).

The Directors' report and statement of accounts for the year ended December 31st last (to be presented at the thirty-second general meeting, to be held at Cannon-street Hotel, London, on Thursday next, at 12 o'clock) are to hand, and appended to the accounts is the auditor's certificate, which is one to which shareholders may well pay more than usual attention. It is as follows:—

"I have examined the above balance-sheet with the head-office books and vouchers and the returns from Silvertown, Persan and the agencies; and, although not exactly in accordance with the form prescribed by the Articles of Association, it is, in my opinion, a fair and true balance-sheet, properly drawn up so as to exhibit a correct view of the Company's affairs, as shown by the books and returns of the Company, subject to the correctness of the value placed on the 'Debentures and Shares in other Companies,' and certain debts included in the item of 'Debts owing to the Company,' as to which I am unable to certify. Any possible contingencies with respect to these, however, are amply provided for by the reserve fund. The subsidiary books have, as usual, been examined in totals. I have had produced to me the inventories of stock of Silvertown, certified by the works manager. "J. F. Clarke, Auditor."

The accounts show that, after provision for doubtful debts, a net profit has been made of £49,325. 12s. Adding £20,913. 17s. 4d. brought forward, and deducting £12,500 interim dividend paid in July, there remains a disposable balance of £57,739. 9s. 4d. The Directors recommend the distribution of a dividend of 15s. per share, free of income tax amounting to £37,500, making, with the interim dividend, a total pay-

Digitized by Google

ment of 10 per cent. for the year, and carrying forward £20,239. 9s. 4d. The report states that the year's general business has been satisfactory; that the cable department and steamships have been moderately employed, and that the Silvertown and Persan factories are in good order.

It is satisfactory to find the announcement that before the next accounts are presented the Directors will propose alterations "in the Company's Articles of Association" as to the form of balance-sheet and profit and loss account "to meet the suggestion of the auditor" in the certificate to which we have referred above. It will be seen, on reference to the document itself, that for meagreness of detail and for "lumpings" this balance-sheet and profit and loss account are bad to beat. We especially commend to the notice of shareholders in the Company the items—

Reserve fund	£450,000	0	0
Debts and loans owing by the Company	150,446	19	4
Debts owing to the Company	275,376	7	3
Stock in trade (including 150 miles of cable laid)	264,217	3	6
Debentures and shares in other companies	210,589	8	0
Cash, stock, &c., after deducting liabilities	135,056	9	7
Gross profit	134,930	0	2

No details whatever are given as to the investments on reserve fund account, nor as to the nature of the "debts and loans owing by the Company." Truly there is room for extended information. At December 31st, 1891, the item "Debentures and shares in other companies" stood at about £25,000, and "debts owing by Company" at about £82,000. The "gross profit" item is more meagre of detail than usual; in the 1894 accounts this was stated as "Gross profit, including interest on securities, and *after charging commission*" (the italics are ours). The interesting and curiosity-invoking term "commission" does not figure anywhere in the present accounts.

The Company's Four and a-Half per Cent. Debentures are repayable next month, and it is intended to issue new Debentures at 4 per cent.

NEW COMPANIES, STATUTORY RETURNS, &c.

CORK ELECTRIC TRAMWAYS COMPANY (LIMITED).—This Company was registered in Dublin on February 3rd, with a nominal capital of £1,000, in £10 shares, to obtain the necessary authority to construct and maintain tramways in the city and County Cork, and to supply the same with electric or other motive power. The first subscribers, with one share each, are: M. Murphy, W. Carter, J.P., James F. Lombard, J.P., J. J. O'Connor, J. F. Murphy, B.L., M. Lombard, and Sir Francis W. Brady, Bart.

FOWLER-WARING CABLES COMPANY (LIMITED).—This Company was registered on February 4th, with a nominal capital of £200,000, in shares of £5 each, to purchase or otherwise acquire and take over as a going concern the business carried on by the Fowler-Waring Cables Company (Limited), incorporated in 1889, together with all or any part of the property, assets and liabilities of the Company in connection therewith; to carry into effect an agreement with the said old Company; to acquire, hold, deal in and grant licences in respect of patents for or relating to electric wires and cables and methods or processes for insulating electric conducting wires and other appliances, and to manufacture, sell and deal in electric and other cables and wires, and all materials, machines and appliances capable of being used for the purposes of telegraphs, telephones, electric light, &c., tubes, pipes, conduits, cables, pulp, paper, rubber, gutta percha, waterproofing fabrics, varnishes, &c. The subscribers, with one share each, are: George Fleming, Alfred E. Mavor, electrical engineer, 32, Victoria-street, S.W.; Lord Medway, J.P.; Walter Chamberlain, manufacturer, Harborne Hall, Birmingham; George F. Smart, William Fowler, engineer, 6, Lombard-street, E.C.; and W. Macintosh. The first Directors are: William Fowler, Walter Chamberlain, George Fleming, Lord Medway, J.P., and George F. Smart. Registered office, 32, Victoria-street, Westminster, London, S.W.

GENERAL CONSTRUCTION AND TRAMROADS COMPANY (LIMITED.)—This Company was registered on January 31st, with a nominal capital of £11,000, in £100 shares, to further the construction, equipment, and development of tramways, tramroads and light railways, and to carry on business as promotors, concessionaires, and contractors for public and private works. Mr. Edward Mather, civil engineer, of Salford Iron Works, Manchester, is one of the signatories, and subscribes for 25 shares. The first Directors are: B. Sykes, G. Flett, Edward Hopkinson, D.Sc., T. S. Turnbull and A. Bruce.

MACMILLAN AND CO. (LIMITED), Publishers.—This Company was registered on January 31st, with a capital of £240,000, in 1,400 Six per Cent. Preference and 1,000 Ordinary shares of £100 each, to acquire as a going concern the business of publishers and booksellers carried on in London under the style of "Macmillan and Co." The first Directors are G. L. Craik, F. O. Macmillan, G. A. Macmillan and M. C. Macmillan.

GUILDFORD ELECTRICITY SUPPLY COMPANY (LIMITED).—The annual return to December 18th was recently filed. The nominal capital is £20,000, in 3,900 Ordinary shares of £5 each, and 500 Founders' shares of £1 each. 974 of the former and 482 of the latter have been subscribed for, and £2 per share has been called on the Ordinary, and the full amount on the Founders' shares.

W. AND J. ROBINSON AND CO. (LIMITED).—An agreement has been entered into by this Company with Messrs. W. H. and J. L. Robinson, electrical engineers, of Bootle, by which it is agreed that the balance of the purchase price of the business acquired by the Company (£7,100) shall be paid to Messrs. Robinson, as to £2,600 thereof in cash, £2,500 by the allotment of 100 fully-paid shares (Nos. 3,233 to 3,732), and the remaining £2,500 by the issue of debentures.

UNIVERSAL ELECTRIC CARRIAGE SYNDICATE (LIMITED).—An agreement has been made by this Company with Mr. Walter C. Bersey for the acquisition of Patent No. 7,240 (1894) for adaptation of electric motors and mechanism to ordinary existing horse vehicles, Patent No. 17,445 (1894) for an electric magnetic friction driving clutch, application for Patent No. 37,019 (1895) for improvements in connection with the driving gear for giving motion to vehicles propelled by electricity, and application No. 16,521 (1895) for improvements in connection with the overhead system of electric traction. The consideration is the allotment of £2,500 in fully-paid shares of the Company.

VENEZUELA TELEPHONE AND ELECTRICAL APPLIANCES COMPANY (LIMITED).—The annual return to January 14th has been filed. The whole nominal capital of £70,000, in £1 shares, has been taken up, and 56,506 shares have been issued as fully paid, while the full amount has been called and paid on the remainder,

CITY NOTES.

MEMORANDA.—Bank rate, 2 per cent. (Feb. 22, 1894). Price of silver, 30⅞d. per oz. (Feb. 13th). Consols (2¾ per cent.) 108⅜–108½ for money, 108 7/16–108 9/16 for account; 2½ per cent. 105—105½ (Feb. 13th). Stock Exchange Settling Days: Consols, March 2nd; Stocks and Shares Continuation Day, Feb. 25th; Ticket Day, Feb. 26th; Pay Day, Feb. 27th; Mining Share Carry-over Day, Feb. 24th.

CASTNER-KELLNER ALKALI COMPANY (LIMITED).—The statutory meeting of this Company was held on the 6th inst. at the Cannon-street Hotel. The Chairman (Mr. W. Mather) stated that the Directors had secured a very convenient site for the erection of works at Weston Point. Building operations had already been commenced, and the work would be vigorously proceeded with during the next few months. The Chairman next referred to the fact that the Deutsche Solvay Werke Gesellschaft, who had been making investigations into the Castner-Kellner electrolytic processes, had been so satisfied with the results obtained that they had not only subscribed largely to the capital of the Castner-Kellner Company, but they had also decided to erect works in Germany simultaneously with the works which were being erected here. For the first few months the Directors intended to confine themselves to one-fourth of the plant they eventually contemplated putting down, and thus they would get such advantage as time and experience would give them.

CENTRAL LONDON RAILWAY COMPANY (LIMITED).—The half-yearly ordinary general meeting of this Company will be held on Wednesday, the 26th inst., at the Cannon-street Hotel, at three o'clock, to receive the Directors' report. An extraordinary general meeting will be afterwards held for the purpose of passing a resolution authorising the raising of £150,000 additional Ordinary capital by the issue of 15,000 new shares of £10 each. The transfer books of the Company will be closed from the 20th to the 26th inst. inclusive.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended February 9th were £972, against £1,022 in the corresponding week of 1895, a decrease of £50. The total receipts for the half-year amount to £5,997, against £6,041 for the corresponding period of 1895, a decrease of £44.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—The Directors of this Company have decided to recommend to the shareholders at the forthcoming meeting the payment of the following dividends (subject to the completion of the audit): 6s. per share on the Preference shares for the second half-year, making, with the interim dividend already paid, a total distribution of 6 per cent. for the year 1895, and 10s. per share on the Ordinary shares for the year 1895, being at the rate of 5 per cent. per annum. Notice is given that the transfer books and registers of members of this Company are closed from the 7th to the 21st inst. inclusive.

GAS LIGHT AND COKE COMPANY.—At the half-yearly meeting of this Company last week the Chairman (Col. W. T. Makins), in moving the adoption of the report and accounts, congratulated the shareholders upon the fact that "in spite of the competition of the electric light," the use of gas for public lighting was still on the increase. Col. Makins, doubtless, meant to say this gratifying state of affairs was in consequence of, and not in spite of the competition of, the electric light. Citizens who have the advantage of the electric light in one quarter are no longer satisfied with dimly lit, but by no means religiously lit, streets elsewhere, and demand increased light, which, as often as not, is provided in minor thoroughfares by additions to or improvements in the gas burners. This naturally leads to increased consumption, but cannot be truly said to be brought about "in spite of the competition of the electric light."

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended the 9th inst. amounted to £1,090. The amount for the corresponding week last year was £859. Increase, £231.

STOCK EXCHANGE NOTICES.—The Stock Exchange Commiteee have appointed Monday, the 17th inst., a special settling day in 200,000 shares (Nos. 100,001 to 300,000) of the Castner-Kellner Alkali Company (Limited), and have ordered the same to be quoted in the official list.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY (LTD.).—The Directors of this Company propose to pay a balance dividend of 10 per cent. (£1. 4s. per share), making 15 per cent. for the year 1895.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended February 7th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,848.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861–1878.

No. 927. [Vol. No. 17. XXXVI.] FRIDAY, FEBRUARY 21, 1896. PRICE SIXPENCE.

NOTES.

An Association, with offices at 27, Chancery-lane, to be known as the United Kingdom Telephone Defence Association, has just been launched, with a strong Executive Council, an influential General Council and a whole series of extremely laudable objects. The motive force of the Association, the Executive Council, consists of Prof. Silvanus Thompson, Mr. R. E. Crompton, Major-Gen. Webber, Mr. A. R. Bennett, Prof. A. B. W. Kennedy, Mr. C. R. Haig, Mr. H. H. Bridgman, ex-chairman of the City Commissioners of Sewers, and Mr. James Swinburne—a veritable Ministry of All the Talents, scientific, technical and commercial.

The objects of this organisation, as set forth in the admirably lucid and highly persuasive circular which is being distributed broadcast amongst the National Telephone Company's *clientèle*, are in general to secure an improved service at a reduced rate, and in particular to place the telephone subscriber's case in an effectual manner before the Telephone Select Committee, should this Committee attempt to renew its Sisyphean labour of piling up mountains of official and interested evidence to be toppled over, as soon as raised, by arguments and evidence the Committee refuses to listen to. If the Association continue as it has begun it should prove a much-needed telephonic anti-soporific. The last paragraph of the "Objects of the Association" is a somewhat vague, self-denying ordinance. Unless the United Kingdom Telephone Defence Association is in every sense of the term "to be registered as an association without profit," as was to all practical intent the whilom Association for the Protection of Telephonic Subscribers, the members would do well to insist that everyone belonging to one or other of its two councils shall pledge himself not to go over to the enemy, either as a director or as an official, without the consent of a clear majority of the members of the Association. The National Telephone Company, it must not be forgotten, is an adept at amalgamation and absorption.

In another column will be found a copy of Major Cardew's Report on the recent fatality at Cheltenham. The circumstances under which the accident occurred are set forth with exemplary brevity and lucidity by the Board of Trade Inspector, and his recommendations and remarks are worthy of the careful attention of all central station engineers responsible for high-pressure systems, who will be well-advised to set their houses in order before the inevitable "accident" occurs. In the ordinary acceptation of the word, an accident is an occurrence which, humanly speaking, could not have been foreseen; we decline to admit that the term is applicable to a fatality which arose from sending an unfortunate carpenter into a more or less crowded transformer-chamber to drill holes at a distance of a few inches from a number of innocent-looking but deadly metal surfaces. Under the conditions which obtained, it surely required a minimum amount of prescience to foresee an "accident" and, with 2,000 volts pressure, a fatality. It is not a question of elaborate and expensive precautions in view of a remote contingency best guarded against by the exercise of individual care, but merely of employing a few cheap and obvious devices to ward off mishaps which must otherwise inevitably happen at short intervals. Electrical engineers may be assured that the moderate suggestions as to safety appliances made by the Board of Trade will be converted into orders, and stringent orders too, if by any chance a public outcry should be raised. The policy of shutting the stable door after the horse has got out is as inexpedient as it is expensive.

The decision of the London County Council, notwithstanding Earl Russell's weighty arguments, to again oppose the Bill of the London United Tramways Company, in which power is sought to make use of the overhead trolley, is a typical instance of the gratuitous obstacles that are in this enlightened country placed in the way of tramway improvements. Insecure tenure, lack of capital, and a stationary traffic are too often the lot of our English tramway concerns, and are in themselves almost sufficient to entirely arrest the introduction of improved methods of traction. The London County Council, however, with a grand display of fidgety anxiety about the beauty of London, preferred to make quite sure that a capitalist concern should in no way prosper, and summarily vetoed a system of traction which has found favour not merely in far away America but in Bristol and Coventry and in many Continental cities, where the beauty of the streets is generally considered to exceed even the elusive charm of the Uxbridge-road from Shepherd's Bush outwards. We yield to no one in a desire that engineering "improvements" should not be permitted to further disfigure the metropolis of the Empire; but high as is our opinion of

Digitized by Google

the capabilities of the modern engineer, we must confess we never thought him capable of disfiguring the many dreary roads that lead out of London. By all means insist, if need be, on a conduit system in the central portions of London; but why refuse the inhabitants of Shepherd's Bush the boon of getting away from their hideous surroundings as fast as the electric car can take them; they are the persons most concerned, and by all accounts do not object to the proposed innovation. The overhead trolley, whatever its demerits—mechanical, electrical or æsthetic—and they are many, will always be the cheapest to erect, and, therefore, so long as our tramways are in the hands of companies liable to be bought out on onerous terms by the local authorities, this single advantage will rightly carry great weight, and should in all fairness and in all good sense be allowed to do so. When tramways are laid down by philanthropists, it will be time enough to expect a lavish capital outlay without thought of return.

Mr. H. F. Parshall's lecture at the Society of Arts on Tuesday evening last was essentially American, and came as a relief to the heavy Papers to which we are accustomed. It consisted of ten minutes' pleasant talk and of a forty-minute long procession of lantern slides illustrating some of the most recent and important improvements in electric traction. The lecturer did not trouble his audience with much description, but contented himself with pointing out a few of the most interesting details, and left the rest to the imagination. Indeed, Mr. Parshall's splendid series of photographs spoke more eloquently for the possibilities of electric traction than any words could. It was specially interesting to notice the huge steam dynamo units used for power stations; machines of from 1,000 to 1,500 kilowatts being by no means uncommon. The change of American practice from high-speed dynamos, driven by belting from a countershaft, to slow-speed direct-driven units, is a curious one and shows how transatlantic engineers have profited by European experience. High-speed engines of the Willans type have not found favour, possibly because the type is not thought suitable for the horse-powers common in the United States. The fly-wheel armature type of machine which was originated on the Continent seems to be preferred. American shafts, armature-plates, commutators, &c., are such large scale productions as to make it somewhat difficult for stay-at-home English electrical engineers to form an adequate conception of them. For example, a commutator weighing rather over two tons, with nearly 700 segments, requires time as well as imagination to mentally digest. The series-parallel starting device, which has been invented over and over again, and has been the subject of much investigation both in Europe and America, has been finally adopted as the method of starting and controlling tramcars. Indeed, it was always felt to be the proper method, and was not adopted sooner simply from mechanical difficulties in dealing with the changes of connections. The chief obstacle lay in the opening of the circuit before changing the motors into parallel. This has been overcome by short-circuiting one of the motors before placing it in parallel with the other. The American device of blowing out arcs at the switch contacts is of special importance and is little known in this country.

Two very valuable items of information were given to the meeting by Capt. Griffiths of the General Electric Company. The first was that the substitution of the series-parallel control for the rheostatic control on the lines at Boston had enabled the West End Company to double the number cars running without adding to its power plant. The second item of news was to the effect that experience with the two slotted-conduit lines now in operation in New York and Washington respectively showed that although the first cost of the system was high (£17,000 per mile of single track), the working cost was less than with the trolley. It is interesting to note the conversion of the General Electric Company. Only a year or so ago that powerful concern was engaged in the evidently congenial task of belittling any and every system of electric traction other than the one the patents of which it controlled.

The Belt-line tunnel locomotives were referred to by the lecturer, and some details of their performance will, no doubt, cause astonishment among those still sceptical about the tractive effort of electric motors. These "locos." weigh 96 tons, and have eight wheels coupled to four independent axles, each of which carries a gearless motor rated at about 100 B.H.P. The weight per wheel is thus 12 tons, or 5 tons in excess of ordinary steam locomotive practice. The brasses, Mr. Parshall explained, were designed for the full load according to usual practice, and no difficulty had been experienced since last August. The even torque caused no pounding and it was quite possible to load the wheels to a greater extent than in steam practice without damaging the brasses or the permanent way. The electric locomotives were designed to haul freight trains weighing, with their locomotives, roughly 400 tons each, through a tunnel with an up gradient of 0·8 per cent. They not only do this work quite easily, but one of them, on one occasion, hauled three trains, weighing together nearly 1,900 tons. The train was stopped in the middle of the incline and was started again without a hitch.

If writers of scientific Papers are going to follow the example set by the author of an American Paper, entitled "The Gross Untrustworthiness of Fuse Metals and Appliances as a Means of Protection for Electric Circuits," we may expect to find more vigour than elegance in the files of the future proceedings of scientific societies. Such a title as "The Atrocious Drop in Copper Feeders," or "The Preposterously Large Waste of Energy in Boosters," would, no doubt, have some advantage over a milder title, in giving prior notice of the author's opinions, and might even induce some people to "come up for the discussion" whom a colourless title would fail to draw from their fireside. The discussion, however, would probably be as unparliamentary in its brusqueness as the title itself, or even more so; and things might go from bad to worse when once the expletive ball had been set a-rolling. Taking one consideration with another, therefore, a return to the use of tame titles is to be recommended.

Digitized by Google

But the matter of this Paper on fuses is more to be commended than its title. It takes the form of a report to the Philadelphia Board of Fire Underwriters, and, after an exhaustive discussion of all the vices which metal safety fuses are prone to develop, recommends that in all important places they should be replaced by automatic magnetic cut-outs. These, it is further recommended, should not contain springs, which would be likely to be let down in temper by the heat generated by the current. The maximum limit of current for which metal fuses might be used is placed at 10 amperes; but we should prefer that the limit should be determined not only by the current, but also by the power to be carried by the circuit controlled. A short circuit on 10 amperes with 100 volts would not be the same phenomenon that it would be on a 10-ampere 10,000-volt circuit. The practical hindrance to the general use of electromagnetic cut-outs has been their large cost relative to fuses, and it is to be feared that this will continue to militate against their extensive use in house installations. Up to the present time magnetic cut-outs have not, perhaps, been used in electric supply stations to the extent their merits warrant; but they are to be found on the switchboards of nearly all, if not all, electric traction stations in this country. One advantage which the electromagnetic cut-out possesses over the fuse should not be forgotten, viz., that it can be constructed to open both positive and negative leads in the event of either going wrong, whereas with a double-pole fuse it does not necessarily happen that both fuses will blow.

Time cannot wither, nor custom stale, the infinite variety of the Röntgen ray. To-day we print in our correspondence columns letters from Lord Blythswood, Mr. C. E. S. Phillips. and Mr. C. J. P. Cave, and a translation of a Paper just communicated to the Royal Academy of Bologna by Prof. Righi, Mr. Phillips finds flames are transparent, and Mr. Cave gives some interesting particulars with regard to the great increase in what may be termed the "sparking capacity" of a pair of terminals which is caused by the incidence of Röntgen rays. Prof. Righi, like Profs. J. J. Thomson and Borgmann, finds that both negatively and positively-charged bodies are diselectrified by Röntgen rays. Prof. Righi has also observed their electrifying power, but unlike Prof. Borgmann, he finds the electrification *positive*. In view of these and other contradictory results, it may be permissible to suggest that Röntgen-ray experimenters would be well advised in stopping further experiments for a while and in assembling together in Congress for the purpose of standardising experimental conditions.

Perhaps the most interesting addition to our knowledge is that made at the Royal Society last week by Prof. Dewar, who from a large number of experiments argues that opacity increases with atomic weight, not with the density merely, as stated by Röntgen. As was recorded on p. 524 of our last issue, M. V. Chabaud found mercury more opaque than platinum; now the atomic weights of mercury and platinum are respectively 200 and 194, whilst their densities are 13·6 and 21·5. An interesting case in point.

Cable Interruptions and Repairs :—

	Date of Interruption.
Puerto Plata—Martinique	December 19, 1895
Perim—Obock	January 2, 1896
Odessa—Constantinople	January 17, 1896

Expiring Patents.—On Thursday next, the 28th inst., will expire Patent No. 941, granted to J. Richardson, of the firm of Robey and Co., for "An Improved Arrangement of Appliances for Electrically Controlling and Regulating the Speed of Engines Employed for Driving Dynamo-electric Machines." The specification describes an arrangement of solenoids, by means of which the engine valves are controlled by the dynamo.

The Municipalisation of Telephones.—A town's meeting, presided over by the Lord Mayor, was held at Manchester on Tuesday last to consider the question of the Corporation undertaking to provide telephonic communication throughout the district. The attendance, which was very large, included the leading merchants and manufacturers of the city. A resolution in favour of applying to the Post Office for the necessary powers to carry out the project was submitted, but was rejected by a large majority.

The 1900 Paris Exhibition.—The Committee of the Paris International Exhibition of 1900 has rejected the Government proposal to incorporate the Champs Elysées, or any portion thereof, in the exhibition grounds. The Palais de l'Industrie will remain intact, and the Exhibition grounds will be exclusively on the left bank of the Seine. However, the verdict of the Committee will not annul the Government scheme, and there is some prospect of the original scheme being carried out in its entirety.

Röntgen Ray Photography.—In the *Comptes Rendus* for February 10th, M. Charles Henry gives a recipe for increasing the photographic action of Röntgen rays. M. Henry smears some of his phosphorescent sulphide of zinc to a depth of about ·5 mm. or 1 mm. on the *back* of a gelatino-bromide plate, and finds that a notable increase in the photographic action is the result. He further finds that a layer of the same substance on the face of a coin or similar object renders it decidedly more transparent to Röntgen rays.

The London-Paris Telephone Line.—The indefatigable Mr. Henniker Heaton, after rebuffs from three successive English Governments, has succeeded in obtaining from the more polite authorities across the Channel statistics with regard to the telephonic communications exchanged between London and Paris. These amounted in 1894 to 45,115, which, at the rate of 8s. for each conversation, represents a total income of £18,046. The number of conversations originating in Paris was less than that of the conversations started from London. The former only reached the number of 18,930, while the latter amounted to 26,185.

Accident at the Southport Central Station.—A few minutes before three o'clock on Wednesday morning, last week, information was received by telephone at the Central Police Office that a man had been injured at the electric light works at Blowick. It was found that an engine-man employed at the works was suffering from an electric shock, together with severe injuries to the right hand and right leg. He was conveyed to the infirmary. It is stated that the man received his injuries owing to the fact that he was not wearing india-rubber gloves, which it is customary at Southport to use when any work is being done in connection with the machinery. Had not a fellow-workman been at hand to render assistance the result would probably have been more serious.

International Horse and Horseless Carriage and Roads Locomotion Exhibition.—Our readers will probably be pleased to hear that at the forthcoming exhibition to be held at the Crystal Palace of all things appertaining to carriages and automotor vehicles, the interest of electrical engineering will be carefully watched over. We understand that Mr. A. R. Sennett, A.M.I.C.E., M.I.E.E., has accepted the position of Honorary Executive Commissioner. In addition to the class of electrically-propelled vehicles, there will be others for electric motors, special gears, accumulators, primary batteries, &c., as well as accessories such as electric lamps for the lighting of vehicles,

Digitized by Google

tricycles, &c. The classification is not yet quite complete, and the Executive Commissioner would be glad of any proposals readers may care to send to him addressed to the Crystal Palace. Mr. Sennett is anxious to see electric vehicular propulsion take its fair position, and he will be glad to receive as soon as possible particulars from such of our readers who may be proposing to exhibit electrical vehicles in action, as to their requirements in regard to the recharging of accumulators in order that proper provision may be made.

The Measurement of High Potential Difference.—In a Paper recently read before the Royal Society, Messrs. H. C. Leake, R. Leventhorpe and C. S. Whitehead described some methods of measuring high potential difference. The Paper is divided into two parts. In Part I. the question of the measurement of high potential difference in terms of the absolute electromagnetic unit is considered, more especially with reference to the calibration of electrostatic voltmeters. After describing Lord Kelvin's method of multiplying a comparatively small known potential difference by means of a series of condensers, a full account is given of the method adopted by Prof. Ayrton and Mr. T. Mather for the calibration of their electrostatic voltmeters. The apparatus is arranged for the determination of alternating potential differences up to several thousand volts, either by measurement of the current passing through a non-conductive manganin resistance of about 20,000 ohms, or by comparison with the steady potential difference of the Clark standard cell, in a way that does not involve any measurements of resistance. It is probable that the measurements made in this way of potential differences of about 2,000 volts are correct to about $\frac{1}{10}$ per cent. in absolute units. Part II. discusses the measurement of high potential difference in terms of the absolute electrostatic unit.

Trials of the Laval Steam Turbine.—At a recent meeting of the Société Internationale des Electriciens, M. L. Fayot gave some particulars of a number of trials of the Laval steam turbine. The first of these was made on a 50 H.P. turbine, coupled to a dynamo, on July 7, 1895. The electrical horse-power developed was 48·64, and the steam consumption during a trial of 3hr. 30min. duration was 3,960lb., or 23·2lb. per horse-power per hour. The second series of trials referred to by M. Fayot was the series conducted at the Bordeaux Exhibition, an account of which has already been given in *The Electrician*, December 27, 1895. On November 10, 1895, a trial of a 100H.P. turbine was conducted at Vienna, under the direction of M. Desjuzeur. The turbine was rope-geared to a dynamo and ran for 10 hours, the steam consumption being 25·41lb. per electrical horse-power at the terminals of the dynamo. This is estimated as being equivalent to 19·58lb. per brake horse-power at the turbine shaft. Prior to the above-mentioned trial the turbine had run for 3,300 hours, and having been stopped on Saturday night for making ready, it was placed on trial during Sunday. Next follows a trial of three turbines at the electric supply station of the Place Clichy, in Paris. The engines were each rated at 75 H.P., and the trial was conducted by M. Compère. A steam consumption of 23·9lb. per electrical horse-power per hour was realised, which was estimated to be equivalent to 20·3lb. per brake horse-power at the turbine shaft. Finally there is an account of a trial of a 200 H.P. turbine, arranged to run at half-load. The trial was conducted at Troyes, and was of a somewhat elaborate nature. Tests were made of the variation of steam consumption with the initial pressure, &c., and the results are recorded in the form of a series of curves. The utility of these curves is somewhat marred by the omission of some of the lettering referred to in the text.

Blast Furnaces Struck by Lightning.—The *Engineer* states that at some ironworks in an exposed situation near the banks of the Rhine the workmen had often reported that lightning seemed to strike the tops of the blast furnaces, and even enter them. instead of being attracted by the lightning conductor on the chimney, which is at a much greater elevation. Though little credence was given to these reports, the men were instructed to keep a strict watch upon such phenomena in future. During eight years they stated that the furnaces were struck three times, while out of ten lightning flashes only one was attracted by the lightning conductor, the others chiefly striking piles of puddle bars. On one occasion, however, Herr Franz Büttgenbach was showing some colleagues over the works, and was with them at one of the furnace tops, when a flash of lightning struck the furnace, which trembled and rattled. The visitors and two furnacemen were stunned, but on coming to themselves they all declared that they saw a pillar of fire entering the furnace mouth. At the top of the furnace, however, nothing unusual was noticed, except that the thick coating of dust which covered the plate-iron shield was driven off; but the men at the bottom reported that the slag, flowing from the furnace in a slow stream, had flowed more quickly for a little while, as when a furnace is tapped. They too considered that the lightning had entered the furnace because of its rumbling and trembling. The furnace was then carefully examined, but no damage was observed, nor any change in its working. The next cast of metal also appeared normal; and analysis of the pig revealed no change in composition. Herr Büttgenbach, who communicates his experience to *Glückauf* of Essen-an-der-Ruhr, observes that he could now believe the men's former declarations that such phenomena were repeated at two of the furnaces every year, but always without leaving any appreciable trace behind. He considers that the reason the lightning entered the furnace, instead of being attracted by the lightning conductor, was that a compact pillar of smoke, containing much water and dust, rose to a height of 40m. above each furnace mouth, forming a good conductor of electricity, which must have passed through the furnace charge, out at the pig bed, and into the earth without doing any damage; but he regrets that the pig of the cast immediately following the lightning discharge was not examined under a microscope, which might have revealed differences of structure as compared with normal pig iron.

Contemporary Electrical Science.—In *Wiedemann's Annalen*, No. 2, we find two important Papers on the measurement of "dielectric constants." W. Nernst describes his telephone method, consisting of a bridge with two equal resistances in two branches, a dielectric trough in the third, and a variable capacity and a variable resistance in parallel in the fourth branch. Two opposite terminals are connected with a high-frequency induction coil or alternator, and the other two with a telephone. The latter is reduced to silence as soon as the variable resistance and capacity are the same as those of the dielectric. This method is very convenient and perfect, and the author tried to compare it with an electrometer method. But the latter was found to be too uncertain, until his disciple, J. F. Smale, hit upon the expedient of suspending the electrometer needle, a pointed lamina of platinum, by a quartz fibre and immersing it bodily into the dielectric between terminals surrounding it in semi-elliptical arches. The deflection of the insulated needle, which is charged by induction from the terminals, is proportional to the dielectric constant, and the two methods give highly consistent results.—P. Drude contributes a suggestive little Paper on dielectric resistance, working out the analogy of the magnetic resistance which has been so useful in the study of magnetic fields. He arrives at propositions like the following: The number of lines of force contained in an infinitely thin tube of force is equal to the difference of potential between its terminal points divided by its dielectric resistance. Or: The capacity of a conductor equals the reciprocal of the total resistance of all its tubes of force ranged in parallel, and divided by 4π.—Max Wien describes a very promising-looking apparatus for producing any self-induction "from 5,000 to 10^{10}cm." It consists of a fixed circle of several coils for step-by-step changes, and a concentric coil movable about a diameter to fill up the intervals.—E. Taylor Jones writes on magnetic carrying power and electromagnetic tension, and claims to have driven B up to 74,200 units in his apparatus!—A. D. Cole makes a further contribution towards the justification of Maxwell's celebrated $n^2 = k$ law. For electric waves 3m. to 6m. long, water has a refractive index of 8·95, and alcohol of 5·20. When the wave lengths are shortened to 5cm. the refractive index of water becomes 8·8, but that of alcohol falls to 3·2. It appears that n always approaches a limiting value for infinitely long waves, and that this value satisfies Maxwell's equation.

THE ELECTRIC ARC.

BY HERTHA AYRTON.

(*Concluded from page 228*).

THE RATIO OF THE POWER EXPENDED IN THE SILENT ARC TO THE POWER DEVELOPED BY THE GENERATOR.

In the last article it was shown that with silent arcs, when the length was fixed, the conditions that $\frac{V}{E}$ should have the greatest value were given by the three equations

$$(E-a-bl)^2=4r(c+dl), \quad . \quad . \quad . \quad (10)$$

$$E-a-bl=2Ar, \quad . \quad . \quad . \quad . \quad . \quad (11)$$

and

$$A=\frac{c+dl}{e+fl}. \quad . \quad . \quad . \quad . \quad . \quad (19)$$

It was also pointed out that if we were free to choose the conditions of the arc circuit without regard to anything but obtaining the largest possible value of the ratio of the power expended in the arc to the power developed by the generator —that is, $\frac{V}{E}$,—the ideal conditions were that l should be zero, and that the other three variables should be found from equations (10), (11) and (19) on this assumption. In this case we should have for my carbons

$$E=a+2e=41{\cdot}22 \text{ volts},$$

$$A=\frac{c}{e}=9{\cdot}96 \text{ amperes},$$

$$r=\frac{e^2}{e}=0{\cdot}1175 \text{ ohm},$$

$$\frac{V}{E}=\frac{a+e}{a+2e}=0{\cdot}9716.$$

We are not, however, free to choose our variables in this way. One or more of them is sure to be fixed by quite other considerations, such as the least length of arc that will emit the desired amount of light, the minimum resistance we are compelled to have in the leads, generator, &c.

Having, therefore, considered what happens when l is fixed, we will take each of the other three quantities, E, A and l, as being fixed in turn, and consider under what conditions $\frac{V}{E}$ will be the greatest in each case.

Since it will be found that the resistance external to the arc must in each case be the smallest with which the given conditions can be carried out, I will point out beforehand that in equation (9)

$$r=\frac{E-a-bl+\sqrt{(E-a-bl)^2-4r(c+dl)}}{2A},$$

which connects E, A, l and r, r will be least for *any* simultaneous values of A and l when

$$(E-a-bl)^2=4r(c+dl)$$

—that is, when equations (10) and (11) hold.

Now, first let E be fixed, then since

$$\frac{V}{E}=\frac{E-Ar}{E},$$

$$=1-\frac{Ar}{E},$$

$\frac{V}{E}$ will be greatest when Ar isleast. But from equation (9) we have $2Ar=E-a-bl+\sqrt{(E-a-bl)^2-4r(c+dl)}$, therefore, for a fixed value of E, Ar is least when bl has its largest value, and when also

$$\sqrt{(E-a-bl)^2-4r(c+dl)}$$

is nought. That is, Ar is least, and, therefore, $\frac{V}{E}$ is greatest, when we use the longest silent arc possible with the given E.M.F. and select the resistance external to the arc, so that

$$(E-a-bl)^2=4r(c+dl).$$

The last equation, which is (10), carries with it equation (11), and from the two we find that

$$A=\frac{2(c+dl)}{E-a-bl}.$$

From this last equation it follows that when E is fixed, and l is as great as possible, A is also as great as possible, or $\frac{V}{E}$ is greatest with a fixed E.M.F. when A is the largest silent current that can be maintained flowing through the arc of greatest length that a generator with the fixed E.M.F. can produce.

Now it was shown on p. 225 of the last article that equations (10) and (11) gave the conditions that the line representing the resistance r ohms should be a tangent to the curve connecting P.D. and current for the length of arc $l$mm. Thus it has been shown that when the E.M.F. of the generator is fixed, $\frac{V}{E}$ is the greatest possible when—

(1) The arc is the longest that can be maintained with the fixed E.M.F.;

(2) The line representing the resistance is a tangent to the curve connecting P.D. and current for this greatest length of arc, and represents, therefore, the smallest resistance that can be used with the fixed E.M.F.;

(3) The current is the largest silent current for this greatest length of arc.

But, as shown in the last article, equation (19) gives the connection between the largest silent current for any length of arc and the length of that arc. Therefore we may say that when E is fixed, equations (10), (11) and (19) give the relations between E, A, l and r that make $\frac{V}{E}$ the greatest.

Next let A be fixed, and first let us suppose that l is fixed also. Then from equation (17) (p. 227 of the last article) we see that for $\frac{V}{E}$ to be as large as possible Ar must be as small as possible. But from equation (9) we have that

$$2Ar=E-a-bl+\sqrt{(E-a-bl)^2-4r(c+dl)}.$$

Hence, whatever the length of the arc may be, if A is fixed Ar is least when E is least, and when also

$$(E-a-bl)^2=4r(c+dl).$$

That is, Ar is least—and therefore $\frac{V}{E}$ is greatest—when we use the smallest E.M.F. that will send the fixed current through the arc, and when we select r, so that equations (10) and (11) hold. But when equations (10) and (11) hold the line representing the resistance is a tangent to the curve connecting P.D. and current for the length of arc used. Hence, when A is fixed, $\frac{V}{E}$ is greatest whatever length the arc may have when we use the smallest E.M.F. that will send the fixed current through that length of arc, and when the line representing the resistance is a tangent to the curve connecting P.D. and current for that length of arc.

Next, while A still remains fixed, let l vary. Then, since it has been shown that $\frac{V}{E}$ is greatest, whenever $\frac{Ar}{E}$ is least and that when A is fixed, $\frac{V}{E}$ is greatest when E is least, we must now find what value of l makes $\frac{Ar}{E}$ least, when E is least, when A is fixed, and when equations (10) and (11) hold.

Since E is to be as small as possible, Ar also must evidently be as small as possible. But from equations (10) and (11) we have

$$A^2r=c+dl,$$

or

$$Ar=\frac{c+dl}{A},$$

which, since A is fixed, shows that $c+dl$ must be as small as possible for Ar to be as small as possible. That is, Ar is least, and therefore $\frac{V}{E}$ is greatest, when l is the shortest arc that can be used, with due consideration for the light to be emitted.

Thus, when A is fixed, we find that the conditions for $\frac{V}{E}$ to be as great as possible are—

(1) That the arc shall be the shortest that will emit the desired light;

(2) That the E.M.F. shall be the smallest that will send the fixed current through this arc;

Digitized by Google

(3) That the external resistance shall be such that the line representing it will be a tangent to the curve for this arc at the point where the current is the fixed current, and consequently the resistance must be the smallest with which the fixed current will flow through the shortest length of arc.

Next let r be fixed, and first suppose l to be fixed also. Then, since $\frac{Ar}{E}$ must be as small as possible, we have from equation (9) that $1-\frac{a+bl}{E}+\frac{1}{E}\sqrt{(E-a-bl)^2-4r(c+dl)}$ must be as small as possible. Hence, since l is fixed, E must be as small as possible, and

$$\sqrt{(E-a-bl)^2-4r(c+dl)}$$

must be nought for $\frac{Ar}{E}$ to be least. Thus, whatever the length of the arc may be, if r is fixed, $\frac{Ar}{E}$ is least when E is least, and when

$$(E-a-bl)^2=4r(c+dl)$$

—that is, when E is least, and when equations (10) and (11) hold.

Therefore, whatever the length of the arc may be with which $\frac{V}{E}$ is greatest when r is fixed, the E.M.F. must be the smallest that will maintain that length of arc with the given resistance in circuit, and the line representing the resistance must be a tangent to the curve connecting P.D. and current for that length of arc.

Now let the length of the arc vary, the resistance still remaining fixed. Then, since equation (10) holds, whatever the length of the arc, we get from it

$$E=a+bl+2\sqrt{r(c+dl)},$$

the positive sign only being taken, because from equation (7) (p. 225, *The Electrician*, December 13, 1895) it may be seen that $E-a-bl$ could not be negative. Hence, since E is to be as small as possible for the fixed resistance, l must be as small as it can be consistently with its emitting the desired amount of light. Also, since $\frac{Ar}{E}$ has to be as small as possible, and since r is fixed and E as small as possible, A must also be as small as it can be with the given resistance in circuit.

Thus, when r is fixed, $\frac{V}{E}$ is the greatest possible when,

(1) The arc is the shortest that will give the desired amount of light;

(2) The current is the smallest that will flow through this length of arc with the given resistance in circuit;

(3) The E.M.F. of the generator is the smallest that will maintain that current flowing through that length of arc with the fixed resistance in circuit.

It may not be out of place to give a few examples of the use that may be made of the foregoing methods of securing the largest value of $\frac{V}{E}$ when one or more of the quantities with which we have to deal is fixed by circumstances.

To take first the case of a constant E.M.F., let us consider how to arrange two arcs in series with a dynamo giving a constant E.M.F. of 110 volts, so as to make the ratio of the power expended in the arc to the power developed by the dynamo—that is $\frac{V}{E}$—as large as possible.

There is a constant E.M.F. of 55 volts for each arc and half the resistance in circuit external to the arc, therefore we must make E equal to 55 in equations (10), (11) and (19), to find what current, length of arc and resistance external to the arc will make $\frac{V}{E}$ as large as possible.

In this way we find that roughly

$$A=19{\cdot}6,$$
$$l=4{\cdot}7,$$
$$r=0{\cdot}16,$$
$$\frac{V}{E}=\frac{E-Ar}{E}=0{\cdot}94.$$

These are, of course, the extreme conditions, and if these values were actually used the arc would be very unsteady, for not only would the line representing the resistance be a tangent to the curve connecting P.D. and current, in which case it has been shown that the arc would be unstable (p. 38, *The Electrician*, November 8, 1895), but the current would be the largest silent current for the length of arc, and therefore the arc would be on the point of hissing. But, although we cannot actually use the current, length of arc, and resistance found from equations (10), (11) and (19), yet these will *serve as guides* for the choice of the actual values to be employed, so that $\frac{V}{E}$ may be as large as it is possible to be when the arc is perfectly steady.

Let us then take an arc of 2·5mm. and a current of 14 amperes, so as to be sure of being well within the limits of steadiness. We have now to put E equal to 55, A equal to 14, and l equal to 2·5 in equation (7), which is the *general* equation connecting E, A, l and r. For, as we are not now using the largest current and longest arc that can be maintained with an E.M.F. of 55 volts, we cannot use equations (10), (11) and (19).

Putting the above values for E, A and l in equation (9), we find that roughly

$$r=0{\cdot}6,$$
$$\frac{V}{E}=0{\cdot}85.$$

Hence, with a constant E.M.F. of 55 volts, and with the *solid* carbons I employed, the largest value of $\frac{V}{E}$, when the arc was silent and perfectly steady, would be obtained by having a current of about 14 amperes, an arc of about 2·5mm., and a resistance of about 0·6 ohm in the circuit external to the arc.

With a dynamo having a constant E.M.F. of 110 volts, two such arcs could be maintained in series, and, as each arc would require a resistance of 0·6 ohm in the external circuit, the total resistance in the dynamo, leads and regulating coil would have to be 1·2 ohms, and the ratio of V to E would be the same as when one arc was maintained with a constant E.M.F. of 55 volts—viz., 0·85. Hence, with such an arrangement, 85 per cent. of the power developed by the dynamo would be expended in the arcs.

Next let the current be fixed. This will be the case when there are many arcs in series. We must consider one of these arcs with its proportion of the E.M.F. of the generator, and of the resistance of generator and leads.

Let us take a fixed current of 10 amperes, and let us suppose that the arcs are found to give the most light when they are 3mm. in length.

Then we must put A equal to 10 and l equal to 3 in equations (10) and (11) to find what E.M.F. and resistance to use, so that $\frac{V}{E}$ may be as large as possible. Doing this we find that roughly

$$E=54 \text{ volts},$$
$$r=0{\cdot}43 \text{ ohm},$$
$$\frac{V}{E}=0{\cdot}92.$$

With these values, however, as before, the arcs would be unsteady. We must use a greater E.M.F. and a higher resistance to maintain a steady arc of 3mm. with a current of 10 amperes. With an E.M.F. of 60 volts for each, the arcs would certainly be steady. If, then, we put E equal to 60, A equal to 10, and l equal to 3 in equation (7), we shall find what resistance must be used outside each arc, so that a steady arc may be maintained. In this way we find

$$r=1{\cdot}06,$$

and

$$\frac{V}{E}=0{\cdot}82.$$

Thus, if a constant current of 10 amperes were flowing, and if the arcs were kept exactly 3mm. in length, an E.M.F. of about 60 volts and a resistance external to the arc of about 1 ohm for each arc would, with solid carbons of the diameters I employed, make $\frac{V}{E}$ as large as it could be for the arcs to be in a perfectly stable condition. As, however, they would not remain exactly 3mm.

Digitized by Google

in length, the E.M.F. would rise as the arc lengthened, until the regulator acted and brought the carbons together again. Thus the *average* E.M.F. of the generator should be 60 volts for each arc, and this would be sufficient to allow of the arcs being perfectly stable. In that case we have seen that about 82 per cent. of the power developed by the generator would be consumed in the arcs.

Next let the arc be at such a distance from the dynamo that the resistance of the leads, dynamo and regulating coil cannot be made less than 1 ohm, and let us suppose that under these circumstances an arc of 4mm. gives the best light with uncored carbons of the size and hardness employed in these experiments.

Then, putting r equal to 1 and l equal to 4 in equations (10) and (11), we find that

$$A = 7{\cdot}3 \text{ amperes},$$
$$E = 61{\cdot}8 \text{ volts},$$
$$\frac{V}{E} = 0{\cdot}88.$$

In this case the current must be increased to make the arc steady, for we must *raise* the resistance line (Fig. 46, p. 37, *The Electrician*, November 8, 1895) to make it *cut* the curve instead of *touching* it. Let us then use a current of 11 amperes. Then, putting A equal to 11, l equal to 4, and r equal to 1 in equation (7), we find that roughly

$$E = 63 \text{ volts}$$

and

$$\frac{V}{E} = 0{\cdot}82.$$

Hence, with a resistance of 1 ohm in the circuit external to the arc, an E.M.F. of 63 volts would maintain a steady arc of 4mm. with a current of 11 amperes flowing, and 82 per cent. of the power developed in the generator would be expended in the arc.

The Smallest Resistance that can be Placed Outside a Silent Arc with Given Carbons.

It has been shown that r is always the least resistance that can be placed outside the arc for any given current to flow through a given length of silent arc when equations (10) and (11) express the relations between the variables. From these equations we get $A^2 r = c + d l$, which shows that when l is fixed and r is the smallest resistance that can be placed outside a silent arc of $l$mm. When a current of A amperes is flowing r varies inversely as A^2.

Hence, when the arc is silent and its length is fixed, the smallest external resistance that can be used with any current varies inversely as the square of the current.

From this it follows that with a fixed length of arc the larger the silent current the smaller is the smallest resistance that must be inserted in the external circuit when that current is flowing. Consequently the smallest resistance that can be used in the external circuit at all, when the arc is silent and of the given length, is the smallest with which the largest silent current will flow. Thus the smallest resistance that can be used outside a silent arc of given length is that which is represented by the line which touches the curve connecting P.D. and current for that length of arc at the hissing point.

But the relation between the length of the arc and the current at the hissing point has been shown to be given by equation (19), and the fact that the resistance line is a tangent to the curve is expressed by equations (10) and (11). Therefore from those three equations we can find the smallest external resistance that can be used with *any* silent arc of fixed length.

Not only this, however, but we can also find from the same three equations the smallest external resistance with which a silent arc can be maintained at all. For, from equations (10), (11) and (19), we have

$$r = \frac{(e + f l)^2}{c + d l}, \quad \ldots\ldots \quad (20)$$

or

$$l = \frac{d r - 2 e f \pm \sqrt{(d r - 2 e f)^2 - 4 f^2 (e^2 - c r)}}{2 f^2}. \quad (21)$$

Since the quantity under the root cannot be negative if l is to have a real value,

$(d r - 2 e f)^2$ cannot be less than $4 f^2 (e^2 - c r)$,

or $d^2 r^2 - 4 d r e f + 4 e^2 f^2$ „ „ „ „ $4 e^2 f^2 - 4 c f^2 r$,

or $d^2 r - 4 d e f + 4 c f^2$ „ „ „ „ zero.

Hence

$$d^2 r - 4 d e f + 4 c f^2 = 0$$

gives the smallest value that r can have, and consequently

$$r = \frac{4 f}{d^2} (d e - c f)$$

gives the value of the smallest resistance that can be placed in the circuit outside the arc in order that a silent arc may be maintained at all.

Since this value of r depends only on the constants c, d, e and f, it is apparent that—

In order to maintain a silent arc at all the total resistance external to the arc cannot have less than a certain minimum value, which depends solely on the carbons employed.

By putting the numerical values for the constants in the last equation, it will be found that, with the carbons used in my experiments, if a silent arc is to be maintained at all, the smallest resistance that can be placed in the circuit outside the arc is one of 0·1117 ohms. Further, by substituting 0·1117 for r in equations (10), (11) and (19), it will be found that with that resistance in circuit the length of the arc must be 0·6mm., and the current, which will be the largest that will maintain a silent arc of that length, will be one of 12·7 amperes, while the value of $\frac{V}{E}$ will be 0·967.

Equation (21) gives two values of l that make $\frac{V}{E}$ a maximum for each value of r, but those obtained from the negative root are either negative or so small that practically very little light would escape if the arc were maintained at those lengths. Therefore in practice only the lengths given by the positive root would be used.

The Equation to the Hissing Curve.

I have called the curve $X_1 X_2 X_3$ (Fig. 46, p. 37, *The Electrician*, November 8, 1895) the hissing curve, for convenience sake. The equation

$$A = \frac{c + d l}{e + f l}$$

which I have used throughout this and the last article shows the relation between current and length of arc for all points on this curve. It was obtained in the following way: The P.D. of each point on the curve was plotted as ordinate, with its corresponding length of arc as abscissa, and the result was found to be a very fair straight line, the equation to which was

$$V = 40{\cdot}05 + 2{\cdot}49\, l. \quad \ldots\ldots \quad (22)$$

Equating this value of V to that given by equation (4) (p. 420, *The Electrician*, July 26, 1895), we get

$$40{\cdot}05 + 2{\cdot}49\, l = 38{\cdot}88 + 2{\cdot}074\, l + \frac{11{\cdot}66 + 10{\cdot}54\, l}{A},$$

or

$$A = \frac{11{\cdot}66 + 10{\cdot}54\, l}{1{\cdot}17 + 0{\cdot}416\, l}. \quad \ldots\ldots \quad (23)$$

This equation gives, with a very fair degree of accuracy, the current for each of the points on the curve $X_1 X_2 X_3$ for the different lengths of arc.

If we put equation (23) in the form

$$l = \frac{1{\cdot}17\, A - 11{\cdot}66}{10{\cdot}54 - 0{\cdot}416\, A},$$

it becomes obvious that when

$$10{\cdot}54 - 0{\cdot}416\, A = 0$$

—that is, when $A = 25{\cdot}3$ amperes, l is infinite, and hence, if this equation holds for all lengths of arc, and not only for arcs of from 1mm. to 7mm., *there is a maximum current with which a silent arc can be maintained, and any current greater than this will cause the arc to hiss, however long it may be.* With the carbons I used this maximum current is 25·3 amperes.

Equating the two values of l obtained from equations (22) and (23), we get

$$V - 40{\cdot}05 = 2{\cdot}49 \left(\frac{1{\cdot}17\, A - 11{\cdot}66}{10{\cdot}54 - 0{\cdot}416\, A} \right),$$

or

$$V = 40{\cdot}05 + \frac{2{\cdot}91\, A - 29{\cdot}02}{10{\cdot}54 - 0{\cdot}416\, A}. \quad \ldots\ldots \quad (24)$$

This is the equation to the curve $X_1 X_2 X_3$ when the same axes and units are used as for all the curves in Fig. 46 (p. 37, *The Electrician*, November 8, 1895). Hence equations connecting l and V, l and A, and V and A for all points on the curve

Digitized by Google

$X_1 X_2 X_3$ have been found, and they show that the P.D.'s, currents and lengths of the arcs for the hissing points are connected by very definite laws.

It is pretty evident that laws just as definite connect the points on the curve $W_1 W_2 W_3$ in the same figure, for this curve is almost parallel to $X_1 X_2 X_3$.

On comparing the points for the largest silent current with those for the smallest hissing current for each length of arc, it will be found that the drop of P.D. between the two is between 9 and 11 volts in every case. The average drop is about 10 volts, and for each of three out of the seven lengths of arc it is exactly 10 volts. Turning to the curves obtained by Prof. Ayrton's students with *cored* positive and *solid* negative carbons (Fig. 6, p. 337, *The Electrician*, January 8, 1895), we find that the fall of P.D. between the largest silent and smallest hissing current for each length of arc is just as strikingly constant, but that the average drop in this case is somewhat less, being about 9 volts. Thus it seems that *whether the carbons be cored or uncored, the fall of P.D. that takes place when the arc changes from silent to hissing is constant for any given carbons—that is, it is independent of the length of the arc and of the current that causes hissing.*

The *rise* of P.D., when the arc suddenly becomes silent after hissing, is not quite as great as was the previous drop, the difference being from half a volt to a volt. But the drop when the arc hisses again is the same as it was before, so that the P.D. for both currents is from half a volt to a volt lower after the arc has once hissed than before. If, however, the current be kept at a little below its largest silent value for some time, the P.D. for the largest silent current will resume its normal value.

It may be observed that the P.D. is fairly constant for each silent length of arc when approaching the hissing point, and that the P.D. for all the hissing currents for each length of arc is also fairly constant. Therefore, without knowing the exact values of the currents that are the largest which will flow silently, and the smallest that will cause hissing, we can ascertain the exact value of the *drop* of P.D. that occurs in passing from a silent to a hissing arc of the same length.

The change of the *current* when the arc passes from silence to hissing is, on the other hand, considerably affected by this difficulty of determining the exact current that causes the arc to hiss, and consequently the law governing this change is much less clearly defined than that governing the change of P.D. Indeed, with my carbons the law connecting the length of arc with the change of current when the arc passes from silence to hissing appears to be a straight line law, whereas, with the carbons used by Prof. Ayrton's students alluded to above, this change appears to be constant for all lengths of arc.

Which of these two laws is correct—if either—or whether the first is true for solid carbons and the second when the positive carbon is cored, must be determined by further experiment. But in any case, it is abundantly evident that, in spite of the instability of the arc when it is at the hissing point, the laws connecting the length of the arc with both the change of P.D. and with the change of current, caused by the arc passing from the silent to the hissing state, are perfectly definite.

I have not, in the present series of articles, been able to touch upon the subject of the distribution of potential in the arc, or of the true shape and size of the arc as distinguished from the shape and size of the merely visible portion, but I hope shortly to publish the results of the many experiments I have made on these points.

In conclusion, Prof. Ayrton asks me to express his thanks for the assistance rendered by various groups of students of the Central Technical College, in the carrying out of the earlier of the experiments described in this series of articles; and in particular to one of his assistants, Mr. Brousson, who, with the aid of Messrs. Duthy, O'Gorman, and Cozens Hardy, enthusiastically continued the work during his absence in America, and supplied the latest results that formed part of the Chicago Paper of 1893. Lastly, he desires specially to testify to the independence of thought that was brought to bear by Messrs. Dick, Everett, and Finlay in interpreting the results they obtained, and to the value of their suggestions regarding the methods employed in the inves igation.

For my own part, I have to thank many students of the Central Technical College for kind assistance with my experiments. But, above all, my warmest thanks are due to Mr. Brousson, whose kindness and patience were unfailing, and whose skill and ingenuity helped me to overcome many difficulties in the construction and arrangement of my apparatus.

NOTES ON STEAM SUPERHEATING.*

BY WILLIAM H. PATCHELL.

Nature of Steam Superheating.—Superheated steam is steam of any pressure at a temperature higher than the temperature of its evaporation from water at that pressure. Saturated steam may be superheated by imparting additional heat to it at a constant pressure, during which process its volume increases. By permitting saturated steam of a given pressure to expand without doing work, superheated steam at a lower pressure may be formed. Steam cannot be superheated in the presence of the water from which it was evaporated, owing to the fact that the water takes up the heat and evaporates into further saturated steam. The corollary follows that water cannot exist in the presence of superheated steam; either the surplus heat in the steam will evaporate the water; or, if there be too little surplus heat to evaporate all the water, the steam will immediately become saturated by evaporating as much of the water as it can.

Messrs. Fairbairn and Tate, Hirn, and Siemens, all found that saturated steam was not a true gas, and that its expansion on the application of further heat was at first much greater than that of a perfect gas. When a temperature of about 20°F. above that of the saturated steam was reached, the volume increased at about the same rate as that of a perfect gas. No data appear to be yet available as to the expansion of steam with high degrees of superheat; but there is little doubt that it would be that of a perfect gas. A marked feature in the use of superheated steam is the rapid fall in the superheat from radiation, &c. The reason of this more rapid fall in temperature as compared with saturated steam seems to be that the latter owes its heat-retaining properties to the water spray carried in it. It is only after this water spray has been evaporated that the steam becomes a true gas.

Aim of Superheating.—The greatest advantage to be gained by the use of superheated steam is in engine cylinders, and is due to the immediate absorption of the film of water on the metal surfaces by the surplus heat, thereby counteracting cylinder condensation, which is the heaviest loss in the expansive working of steam. In this connection superheated steam would appear to have an advantage over steam jackets, inasmuch as the heat is applied exactly where it is wanted, and during the period that it is wanted—that is, up to the point of cut-off; whereas a steam jacket wastes a considerable part of its heat and time in warming up the exhaust.

Early Attempts at Superheating.—That economy attends the use of superheated steam in engine cylinders has been known at least since 1828, when Richard Trevithick reported on the engines at Binner Downs Mine in Cornwall.† The engineer of the mine, Capt. Gregor, wishing to rival the record of a neighbouring mine where the cylinders had been cleaded in sawdust, built in his cylinders and steam pipes with brickwork, making a fire-grate underneath them and flues around. The results were unexpected, and the duty of the engine was raised from forty-one to sixty-three million foot-pounds per bushel (84lb.) of coal. Trevithick tested the 70in. cylinder engine, which, when 5 bushels of coal was burned in 24 hours under the cylinder, took 67 bushels under the boiler; when no coal was burned under the cylinder, 108 bushels of coal was used under the boiler for the same work, showing a saving of one-third of the coal by superheating. The steam pressure was 45lb. per square inch, and the strokes eight per minute. With the cylinder fires on, 13 gallons of injection condensing water was used per stroke, and heated from 70deg. to 104deg.; without the cylinder fires, 15½ gallons of condensing water was used per stroke, and heated from 70deg. to 112deg. Trevithick followed this up by inventing in 1832 a tubular boiler, combined with a superheater between the boiler and the engine cylinder; he also jacketed the cylinder with the waste gases from the furnace. In Fig. 1 is shown the arrangement, copied from his patent No. 6,308 of 1832. The external series of vertical pipes, connected top and bottom to a hollow ring, constitute the boiler; the superheating pipes inside it are formed like inverted siphons, so as to avoid jointing at the lower end next the fire. Trevithick had been combating cylinder condensation for 30 years before this date, having in 1802, in conjunction with Vivian, constructed a non-condensing engine, the cylinder of which was placed inside the boiler—a plan followed for many years with much success in agricultural portable engines by Messrs. Hornsby of Grantham.

Owing, doubtless, to the difficulty in controlling the temperature imparted to the steam, superheating made but little headway till 1850, when it came to the front again. Many plans were then proposed for superheaters and steam driers in various forms, both attached to boiler flues and separately fired. Asbestos packings and brass bushes with plumbago plugs were then introduced to meet the demand for steam-tight glands under superheated steam.

More Recent Efforts.—Some results then obtained were reported to this Institution by Mr. John Penn in 1859 (*Proceedings*, p. 195), followed by Mr. John N. Ryder in 1860 (p. 22). Mr. Penn described the apparatus employed by him in the "Valetta" steamer of the Peninsular and Oriental Company, with engines of 260 nominal horse-power, where the saving in fuel due to superheating was 20 per cent. The superheater consisted of two horizontal faggots, each of 44 2in. tubes, placed in the smoke box. The tubes were fixed into three wrought-iron boxes, welded up at the corners and closed with a flanged joint. The steam from the boiler passed into the centre box, thence through the tubes into the end boxes on its way to the engines, taking up heat from the escaping gases, which have been otherwise wasted. The proportions of the apparatus are given by Mr. Penn as $2\frac{3}{4}$ sq. ft. of superheating surface per nominal horse-power; the boilers had a heating surface of 19 sq. ft. per nominal horse-power. The steam pressure was 20lb. per square inch, and the amount of superheat about 100°F.

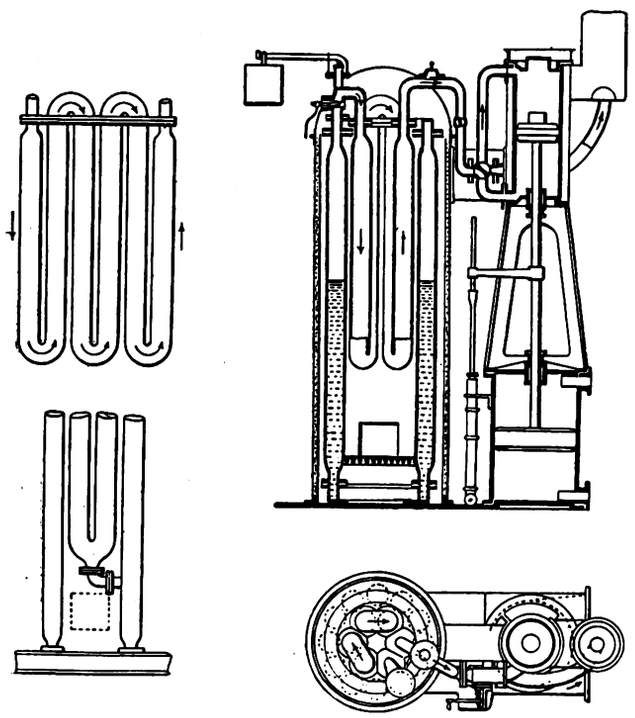

FIG. 1.—Trevithick Superheater.

Mr. John N. Ryder dealt with Messrs. Parson and Pilgrim's apparatus as fitted on marine boilers, and also Mr. David Patridge's superheater. The Parson and Pilgrim apparatus consisted of two horse-shoe pipes fixed over the fire-grate in the internal flue of the boiler. Tests on the steamers "Osprey" and "Swift" showed a saving over saturated steam of 30 to 40 per cent. in fuel; and on H.M. steam-tug "Bustler" a mean of 37 trials with a pressure of $8\frac{1}{2}$lb. and a temperature of 380deg. in the cylinders, which is 144deg. of superheat, gave 25 per cent. economy.

Mr. Patridge's apparatus was a cylinder filled with tubes, placed vertically in the uptake. The gases passed through the tubes and the steam around them; the working temperature was from 360deg. to 390deg. H.M. steamship "Dee" was fitted and tested for several months by the Admiralty, when an economy of fuel of from 20 to 25 per cent. was obtained. An aggregate of about 5,000 H.P. was stated to be then working with this apparatus.

Following closely on Mr. Ryder's Paper was one read by the Hon. John Wethered, of the United States, at the Institution of Civil Engineers (*Proceedings*, 1860, Vol. XIX., p. 462), wherein he animadverted on the futility of the common kinds of superheater, and strongly advised mixed or combined steam, which he claimed to have introduced from America four years previously.

Reasons for Former Abandonment.—If superheating was so common and of such manifest importance and efficiency in the saving of fuel some 40 years ago, the question arises, why was it given up? And what factors that led to its abandonment have been eliminated in modern practice?

Trouble was formerly experienced at the valve faces and in the cylinders from the decomposition and destruction, at the high temperatures of superheated steam, of the tallow and the low-class lubricants then in vogue. This trouble was two-fold: the cutting and excessive wear in the absence of lubrication, and the pitting caused by the fatty acids in the lubricant. On this score, however, no trouble need now be anticipated, at any degree of superheat likely to be attained, where good hydro-carbon oils are used. Gas engines run in regular working with a cylinder temperature in the neighbourhood of 2,000°F., lubricated with good oil; and with ordinary care and attention instances of cutting are not frequent. The common use of metallic packings for glands, and of piston valves in place of flat valves, has removed another serious obstacle. In this connection it will be well to note that pistons and valves which show little leakage when used with saturated steam may show considerable leakage with dry steam, probably owing to the film of water on the metal improving the fit when saturated steam is used.

Much of the trouble that has been attributed to the effects of superheat, in respect of cut cylinders and valve faces, has in the author's opinion been due in reality to the effect of alternate superheat and water in the steam, owing to want of proper control of the

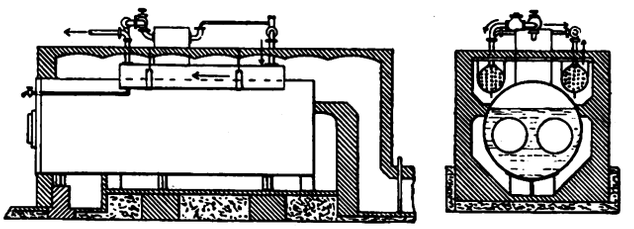

FIG. 2.—Gehre Superheater.

superheaters. A superheater may give a high degree of superheat when the fires are in good order, and at another time may even act as a condenser. The effect of this alternation demands much closer attention than it has at present received. A somewhat parallel case is the behaviour of a good hydro-carbon cylinder oil, which in one engine with normal dry steam leaves no deposit; whereas in a sister engine, at the same steam pressure, with wet steam a heavy deposit is formed from the same oil.

An instance of a cut cylinder which had to be re-bored has lately come under the author's notice, where it appears from the evidence that the trouble is not to be attributed either to the degree of superheat in itself, or to the lubricant, or to neglect on the part of the engineer in charge, but to the alternate effects of superheated and wet steam in the cylinder.

The majority of the old troubles were met with in the engines; but the superheaters themselves do not appear to have been always above reproach. When endeavouring to trace failures to faults in pipes or joints the author has sometimes found superheaters which were fixed with a by-pass for the steam, but none for the gases. The boilers were then worked occasionally with the steam shut off

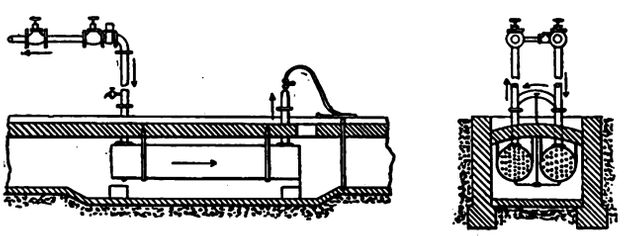

FIG. 3.—Gehre Superheater.

the superheater; and it is not surprising that the latter deteriorated rapidly, its position being eminently unsuitable for a combination of boxes, pipes and expanded tube joints.

Re-introduction of Superheating Apparatus.—Concurrently with the increased efficiencies gained in late years in both boilers and engines, competition has also increased, and with it has arisen the continual cry for cheaper power, cheaper transport, cheaper means of production. The result is that engineers cannot afford to dismiss without careful examination the claims of any plan the adoption of which may diminish their consumption of fuel. It is this fact which has again brought superheating to the front, and has made it the subject of close inquiry in many quarters. Several kinds of superheater are now in more or less extensive use, but only one of them is a radical departure from those of 40 years ago. Any change in the others is rather in manufacture than in design, and their parentage can be traced by their strong family likeness.

Gehre's Superheater.—This is in extensive use on the Continent, and has been introduced into this country by Messrs. B. Donkin and Co., of Bermondsey. It is shown in Figs. 2 and 3, and may be either fitted in the boiler flue or separately fired. Some of these superheaters have been fixed in England, but unfortunately they have not been tested. Mr. Bryan Donkin kindly gave the

author a copy of a test made in Germany, of eight hours' duration, on a water-tube boiler with and without the superheater (Table I.). The heating surface of the boiler was 861 sq. ft., and of the superheater 646 sq. ft. The superheater was placed directly behind the boiler in a special flue.

Hick, Hargreaves and Co.'s Superheater.—By the courtesy of the makers, the author has been favoured with the following particulars and tests, Table II., of their superheating apparatus in a mill at Bolton. As shown in Fig. 4, the apparatus consists of a nest of U tubes, bent to a large radius at the bottom, which are placed at the back of a Lancashire boiler where the hottest gases from the flues impinge upon them. The tubes are suspended from a tube-

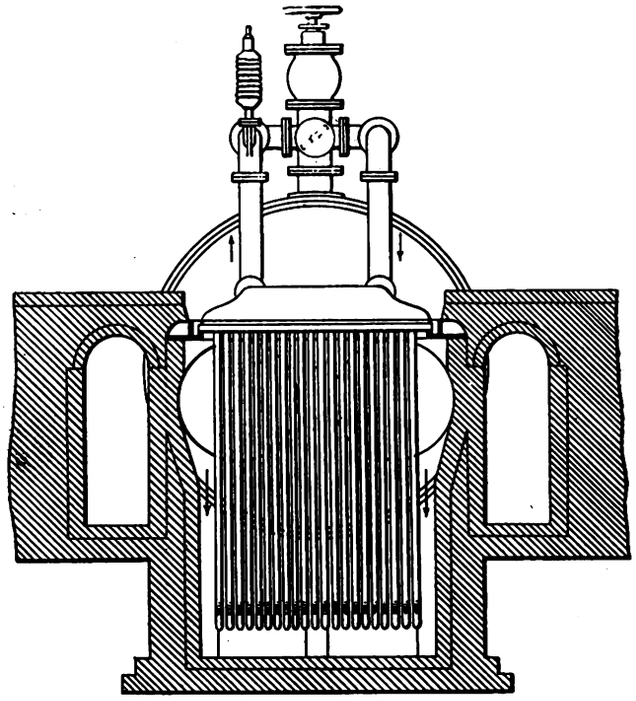

Fig. 4.—Hick, Hargreaves and Co. Superheater.

plate forming the bottom of a box, in which they are fixed by being expanded in the usual manner. The box is divided down the middle by a vertical diaphragm, so that the saturated steam entering at one side passes down and up through the tubes, and leaves superheated at the other side. A by-pass valve is arranged to regulate the flow of steam through the superheater, because only a portion of the steam from the boiler is intended to be superheated. Main valves are also provided, so that the superheater can be disconnected for examination, or even taken out entirely, without interrupting the working of the boiler. The Lancashire boiler to which the superheater is applied is 8½ft. diameter and 30ft. long, with two flues of 3¼ft. diameter, having nine circulating tubes in each. The grate surface is 39 sq. ft.; the heating surface in the boiler is 1,195 sq. ft., and in the superheater 120 sq. ft. The area of passage through the superheating pipes is 22 sq. in. The boiler pressure is 100lb. per square inch above atmosphere. In the tests a portion only of the steam was superheated. The steam pipes to and from the superheater are 3½in. diameter, and are provided with valves, which were kept full open. The main stop-valve on the boiler is 8in. diameter, and was kept only $\frac{5}{16}$ths inch open. The steam was taken to the superheater from underneath this valve, and the return pipe from the superheater was conducted direct to the main range of steam pipe supplying the engine. The temperature of the gases was not taken. The engine is a horizontal tandem compound, fitted with Corliss

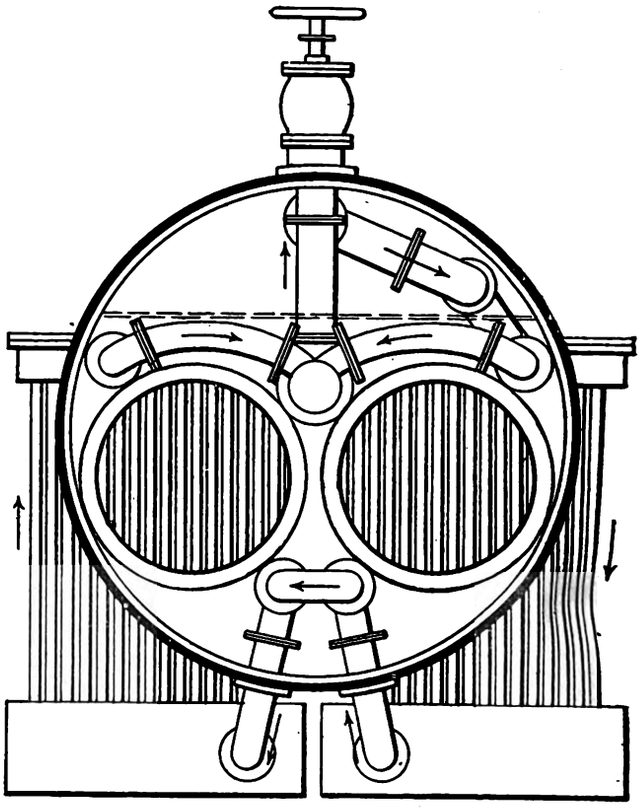

Fig. 5.—McPhail and Simpson Superheater.

The much easier working of the boiler for the same indicated horse-power at the engine is to be noted. During the tests of March 20th-21st and March 26th-27th the load was practically identical. In the former tests with superheating the rate of coal consumption was 18·81b. per square foot of grate per hour, whereas in the latter tests without superheating the combustion went up to 23·41b. of coal per square foot of grate per hour. Where there is a low and uncertain chimney draft, this slower combustion alone would tend to much steadier and more economical steaming, and would more than counterbalance any obstruction in the flues caused by the superheating pipes, which appears to be more imaginary than real.

McPhail and Simpson's Superheater.—This apparatus is the invention of Mr. Hugh McPhail, and is manufactured in Wakefield by McPhail and Simpson's Dry Steam Patents Company. It consists of two parts: the superheater proper; and the steam generator of radiating tubes, which distinguishes it from all other plans. As applied to a Lancashire boiler, Fig. 5, there are two nests of vertical steel tubes, expanded at top and bottom into cast-steel boxes, or "headers" as they are called in water tube boilers; these nests are placed preferably at the back end of the internal flues of the Lancashire boiler, in the down-take, where the furnace gases impinge on them and pass between them. One of the top boxes is connected to the usual anti-priming pipe in the boiler; and the corresponding bottom box is connected to a block, which

Digitized by Google

passes into the bottom of the boiler, and from which a copper pipe runs along the bottom of the boiler under the internal flues to the front end, and thence back again to the rear, where it passes out of the boiler and into the other bottom box. The second top box is connected to another copper pipe, which runs along the boiler over the internal flues, just below the water line, and ends at the main steam stop-valve. The course of the steam is from the anti-priming pipe to the first top box, then down through the superheating tubes to the first bottom box, whence it enters the boiler, and passing through the lower copper pipe gives up part of its superheat to the surrounding water, before leaving the boiler and entering the second bottom box. It is then further superheated in passing up through the second nest of tubes; and thence passing through the second top box into the upper copper pipe in the boiler, it again parts with some of its superheat, before finally leaving the boiler at the steam stop valve.

The complete apparatus thus consists of two external superheaters and two internal radiators; and the final degree of superheat depends upon the proportion of the superheating tubes to the radiating pipes. The function of these radiating pipes is most important, as they give off to the water in the boiler the superheat which might be dangerous in the engines at times of heavy firing; and, when the fires are green after cleaning and the flue gases low in temperature, they prevent any possibility of the superheater becoming a condenser. They thus tend to keep regular the amount of superheat in the steam as it leaves the boiler. It will be evident therefore that this superheater may be arranged either for improving the evaporative efficiency of a boiler, and at the same time giving dry steam at the engine, or for the steam to leave the boiler highly superheated.

(To be concluded).

THE NATURE OF CHEMICAL CHANGE AND THE CONDITIONS WHICH DETERMINE IT.*

(Concluded from page 522.)

The discovery of the nature of the phenomena underlying electrolysis—and therefore those underlying chemical change—may not improbably be assisted by the study of substances other than conducting solutions; and for other reasons also the study of the electrical properties of such substances appears to be of the highest importance.

Thus it is well known that whereas metals generally are relatively good conductors, non-metals oppose a very great resistance to the passage of an electric current. A question of the utmost importance to consider is whether non-metals may not be capable of opposing an infinite resistance, and whether it may not be possible to base on electrical behaviour an absolute distinction between metals and non-metals, although hitherto we have been obliged, on general chemical grounds, to conclude that no line can be drawn, and that, in fact, the metals insensibly shade off into non-metals through the metalloids such as arsenic, tellurium, &c.

As long ago as 1887, in the course of the discussions which took place within the British Association Electrolysis Committee, I drew attention to the importance of making further observations on the specific resistances of the non-metals, pointing out that as these appeared all to behave as electrolytes of very high resistance, it became a question whether this might not arise from the fact that impure substances had been studied, and adding "if sulphur, &c., are found to behave as water—that is, to increase in resistance as they more nearly attain a pure state—then I think we may fairly divide elements into two distinct classes, and define a metal as an element which conducts, and a non-metal as an element which insulates."

The conductivity of what is so wrongly called carbon, in the form used for electric light purposes, is well known to be electrolytic in character, and is, therefore, most probably conditioned by the presence of salts, and not a specific property of the modification of the element present in such materials.

In the case of the metals also, on the other hand, many observations of great interest have been made, which are highly suggestive, and should serve to incite further inquiry.

The electrical conductivity and, at the same time, the mechanical properties of all the highly conducting metals which fall into positions in the periodic system not far removed from that of copper are affected in a most remarkable manner by the presence of minute amounts of impurity, especially by certain non-metallic and metalloïdal impurities. Owing to the very large use which is made of it in telegraphy, no metal has had more attention paid to it than copper, its manufacture having been greatly improved by the introduction of electrolytic methods in place of the old dry methods. Fitzpatrick, in a report of the specific resistance of this metal, published in the *Brit. Assoc. Report* for 1890, gives a value which is better than that found nearly 30 years before by Matthiessen for "pure" copper in the proportion of 100 : 102·6; but my colleague, Prof. Ayrton, tells me that copper of still higher quality, viz., above 103, is now made on a large scale. It is noteworthy that Swan and Rhodin, in a Paper communicated to the Royal Society in 1894 (56, 64), give a value which is not quite so low as that found by Fitzpatrick, viz., 1,563, Fitzpatrick's lowest value being 1,557. They speak of their copper as "pure," stating that it is probable that both of the specimens examined by them were "perfectly pure," and that, in fact, the limit of electrolytic purification has been reached, but this cannot have been the case. Moreover they, as well as Fitzpatrick and all other observers, obtained different values before and after annealing, the specific resistance of the soft wire being 1,563, whilst before annealing it was 1,603—a circumstance which in itself, I venture to think, affords strong presumptive evidence against the conclusion that we are yet come into possession of practically pure copper, and for the following reasons:—

E. van Aubel has observed in the case of bismuth (*Phil. Mag.*, 1889, 28, 332), that although annealing has a considerable effect when the metal is very impure, the effect becomes less and less marked as the impurities are removed, until finally the electrical resistance is scarcely altered by annealing; also there is a considerably greater difference apparent between the values given for hard and soft copper by Matthiessen than has been found by later workers, who, presumably, have dealt with a less impure metal. Therefore it appears not improbable that a pure material would suffer no change on annealing—that it would not require annealing, in fact.

Taking Spring's important investigation into the influence of extreme pressure into account, it appears likely that the change during wire drawing—hardening, to undo which resort is had to annealing—is in itself due to the occurrence of chemical change—that is, change in molecular composition. Barus, in particular, has advocated this view (compare *Nature*, 1890, 41, 369), and it has recently received confirmation from observations made by Unwin on the effect of repeated straining and annealing on the yield points of iron and steel (*Proc. Roy. Soc.*, 1894, 57, 178). But if change in molecular state in a metal be subject to the same laws as are interactions in other cases, a pure material should not undergo change under the influence either of pressure or of heat; and therefore from this point of view also the fact that all copper hitherto examined is softened by annealing may be regarded as evidence that it has contained impurity.

The nature of the "impurity," the character of the changes which take place in such cases, form subjects of inquiry not only interesting in themselves, but also of the highest technical importance. With regard to the former, attention may be called to a statement made by Hartley to the British Association Electrolysis Committee in 1887, pointing out that the preparation of pure copper is extremely difficult; and that such as he had had made for spectroscopic purposes, which was considered *pure*, had been found to contain as sole impurity about one hundred thousandth part of silver, while other samples contained tellurium and bismuth. The photographed spectra were the means of detecting these foreign constituents. I quote this by way of reminder that ordinary or even extraordinary chemical tests are of no use in such cases. It must also not be forgotten that gases may become "occluded" during annealing, and bearing in mind the extreme sensitiveness of copper—especially to oxygen—it would appear necessary in future inquiries to effect the annealing in a "vacuum" from which moisture, oxygen, &c., have been, as far as possible, removed.

As regards the character of the changes brought about in metals by admixture, we are, of course, but on the very fringe of the inquiry; it is certainly cause for congratulation that men like Roberts-Austen, Dewar (and Fleming), Heycock and Neville, and Alder Wright—all our own Fellows—have done so much during recent years to extend our knowledge of the behaviour of metals; and we may confidently expect that, now interest is so generally re-awakened in metals and alloys, we shall ere long be able to arrive at trustworthy conclusions.

Recent observations on the depression of the freezing points of metals seem to show that, in most cases, the liquid metal consists of monatomic molecules—in itself a very noteworthy conclusion, when it is remembered that the very opposite is true of liquefied non-metals. Whether, on solidification, and as cooling takes place, these fundamental molecules form complex groups, is a question which is now being warmly debated, but is a very difficult one to decide: the view advocated by Matthiessen—I am inclined to think with true prescience—that many metals are capable of existing in allotropic modifications—that is to say, in modern language, that they may exist of different degrees of molecular complexity, is at the present time but little approved of, there being a tendency to substitute for it more purely mechanical conceptions. Only in the case of iron is it fairly generally admitted that the facts are such as to make the acceptance of Matthiessen's view almost compulsory. Osmond—whose work is of extraordinary interest

* Abstract of an address delivered by Dr. H. E. Armstrong before the Chemical Society.

Digitized by Google

and of the highest value—indeed has argued that this metal may exist in no fewer than three allotropic forms.

In the case of a pure metal consisting in the fused state of monatomic molecules, it is conceivable that when solidification takes place interatomic forces come into action in such a manner and so uniformly that the mass, as it were, forms one huge complex molecule. This could scarcely happen if impurities were present; but in that case similarly constituted smaller complexes—individual crystals—might form. The observations of Behrens on the microscopic structure of alloys of silver and copper are perhaps of significance from this point of view, showing as they do that, whilst the crystals are scarcely distinguishable in "pure" copper, in copper containing only a minute proportion of silver they become distinctly visible and are seen to be separated by a film of white alloy.

It is difficult to resist the conclusion that the properties even of congeries of such crystal molecules as are above referred to are not somewhat different from those of the simple fundamental molecules *en masse*. Silver, copper and gold, it is well known, are possessed of high electrical conductivity, especially silver and copper, which are all but alike in this respect; and yet, as Matthiessen has shown, when any two of them are mixed, the conductivity of the mixture is lower to an extraordinary extent than that of either alone. That such an effect should be produced is very remarkable, and it is difficult to understand how it can be brought about by the mere admixture of molecules which apparently are equally effective conductors; this behaviour would seem, indeed, to be an indication either that the molecular state of the metal is changed, and that, in fact, it is converted into a modification possessed of lower conductivity; or that a compound of the two metals of lower conductivity is formed and becomes interposed between the highly conducting crystals.*

The remarkable behaviour of silver towards oxygen also serves to suggest that the silver atoms combine on solidification. The fact that this metal is a solvent specifically of oxygen, and not of gases generally, is, in a measure, evidence that combination takes place between it and the gas; and on this assumption the well-known spitting may be explained as due to the occurrence of an interaction conditioned by the superior affinity of silver to silver outweighing that of silver to oxygen in the manner indicated by such an equation as $xAgO_2 = Agx + xO_2$. But this explanation does not necessitate the conclusion that the silver atoms combine otherwise than throughout the whole mass.

The evidence that one metal may combine with another is now so entirely beyond question that it is no longer open to doubt that like metallic atoms may combine. The eminently plastic character of some highly purified metals, *e.g.*, copper, gold, silver, iron, platinum—would, I imagine, lead us to prefer the view that they consist of relatively simple, if not of monatomic molecules. Whilst, on the other hand, the extraordinary brittleness produced on adding small proportions of certain elements to some of these metals is perhaps best explained by the assumption that such additions cause the formation of complex molecules having but little tendency to cohere. Such a conclusion is almost necessary in the case of iron, in which, as is well known, extraordinary alterations may be produced by altering the distribution of the impurities, without altering their amount—I allude to the passage of carbon from the combined into the free state during the rapid cooling of steel, and to the change in the opposite direction which takes place during slow cooling. Iron, indeed, is one of the most remarkable among metals, and there is no literature more deserving of the chemist's attention than that relating to the researches of Roberts-Austen, Barus, Hopkinson, Osmond, and others, who, during recent years, have contributed in a most important manner to our knowledge of the changes going on in iron and steel.

* In view of the possibility that impurities introduced during the preparation of such alloys may exercise an important influence, it is very desirable that Matthiessen's observations should be repeated and extended, using very carefully purified materials. No doubt the greatest care has been taken in purifying both gold and silver, as well as copper, but there is no reason to think, I imagine, that we have attained to finality in such matters. These three metals are so much alike in many of their properties that it is an interesting subject for inquiry whether they may not be still more closely allied, especially in electrical behaviour, than we now suppose them to be, and it is very desirable that they should all be worked at from this point of view. In future, however, it will be necessary to extend the examination so as to determine as many properties as possible, mechanical, physical and structural. If we knew, for example, the specific conductivities, as well as the tensile strength and extensibility, of the various gold alloys prepared by Roberts-Austen (*Phil. Trans.*, 1888, 179, 339), we should be better able to discuss his conclusion that the influence of various metals on the mechanical properties of gold may be co-ordinated with their atomic volumes—a conclusion which it is somewhat difficult to accept when lithium and potassium produce effects which place them at the very opposite ends of the scale. The improvement effected in metals and alloys by the addition of another—as that of aluminium to brass—may doubtless sometimes be traced to the fact that it brings about the removal of an objectionable impurity, and this may well be the effect on gold of some metals.

Osmond assumes that even "pure" iron alters in molecular composition as it cools, basing this conclusion on the observation that the electro-deposited metal exhibited the phenomenon of recalescence; but the conclusion that such iron is, to use Roberts-Austen's expression, "as pure as any iron can be" may fairly be called in question, especially as Osmond speaks of it as containing a little carbon (0·08 per cent., *Iron and Steel Institute*, 1890, i., 38), and it may be doubted whether any such change would take place in pure iron. In presence of carbon, it would seem that when the temperature has fallen sufficiently, molecules which are more complex than those existing at the higher temperature are formed, heat being liberated, thus giving rise to recalescence; the extent to which such complexes are formed largely depending on the amount and character of the impurity present. Perhaps it is from these complex molecules that the peculiar magnetic properties of steel are derived. The separation of carbon from iron may well take place at the moment when the complexes are formed, and the change which occurs at its separation may be of the character of that referred to above in connection with the spitting of silver. The carbide which is produced during slow cooling may conceivably be generated by the interaction of the complex molecular form of iron with the carbon. The explanation of the changes here discussed, advanced by Osmond, involving as it does the assumption that at high temperatures iron consists of the hard modification, which, unless prevented, passes into the soft modification on cooling, seems to me to be less natural and likely than the foregoing.

It is to be hoped that ere long methods will be devised of preparing considerable quantities of iron in a state closely approaching to that of purity, so that the individual influence of various foreign substances may be studied. At present we do not seem to be aware whether the presence of carbon especially is essential to hardening, and whether this element alone can condition the state which renders steel capable of becoming permanently magnetic. Sufficient will have been said, I trust, to emphasize the extraordinary importance of attention being paid to the behaviour of highly purified substances. Enough is known to warrant the assumption that in many cases such investigations will show that properties associated with individual substances are wrongly regarded as specific, and that in reality they are determined by an admixture. To give but one more illustration, if conduction in solids other than metals be always electrolytic conduction, conditioned by the presence of composite electrolytes, a condenser such as a Leyden jar may be regarded as a voltaic cell in which the electrolyte is a solid of high resistance, and its action as dependent on polarisation; the difference between such a cell and one containing a fluid electrolyte arising from the fact that in the latter polarisation cannot be maintained except at the electrodes, whilst in the former the polarisation extends throughout the electrolyte. On this assumption it should be impossible to form a condenser from a pure substance. I venture to point this out as *showing* the great importance of experiments being instituted with *very highly* purified dielectrics.

The more our attention is directed to the important part which impurities play in determining change, whether it be in metals, non-metals or compounds, the more necessary is it to inquire into the possible mechanism by which such change is brought about. So long as we are entirely unaware of the nature of chemical affinity and of the manner in which it is exerted, little progress can be made. There can scarcely be a doubt, however, that what has been termed residual affinity is largely operative, as, indeed, Faraday foresaw. The following remarkable passage in his fifth series of Researches (§ 523) is almost as clear a statement of this view as could be given at the present day:—

"The theory which I have ventured to put forth (almost) requires an admission that in a compound body capable of electro-chemical decomposition the elementary particles have a mutual relation to, and influence upon, each other, extending beyond those with which they are immediately combined. Thus, in water, a particle of hydrogen in combination with oxygen is considered as not altogether indifferent to other particles of oxygen, although they are combined with other particles of hydrogen, but to have an affinity of attraction towards them, which, though it does not at all approach in force, under ordinary circumstances, to that by which it is combined with its own particle, can, under the electric influence, exerted in a definite direction, be made even to surpass it. This general relation of particles already in combination to other particles with which they are not combined is sufficiently distinct in numerous results of a purely chemical character . . . and it probably has a direct relation to, and connection with, attraction of aggregation both in solids and fluids. It is a remarkable circumstance that in gases and vapours where the attraction of aggregation ceases, there likewise the decomposing powers of electricity apparently cease, and there also the chemical action of quantity is no longer evident. It seems not unlikely that the inability to suffer decomposition in these cases may be dependent upon the absence of that mutual attractive relation of the particles which is the cause of aggregation."

Hence, in studying the manner in which chemical change is brought about, we are necessarily obliged to consider valency, comprehending under this term both the quantity and the quality of

Digitized by Google

the "affinity" possessed by atoms. But, again, progress is trammelled by tradition and fashion—the habit of teaching dogmatically has affected our whole attitude towards such questions, our theories being not only unsatisfactory, but eminently narrow in their disregard of facts, especially apparent in our neglect of molecular compounds. Helmholtz, in his Faraday lecture, after dwelling on the conclusion that definite atomic charges of electricity are associated with the atoms of matter, said that he did not suppose that the existence of other molecular forces, working directly from atom to atom, was to be excluded. But is this the case? I venture to think that, had Helmholtz been a chemist, he would have felt compelled to admit that whatever be the nature of chemical affinity, the same forces are active throughout—that what is termed residual affinity is of the nature of ordinary affinity, and that the difference is in quantity rather than quality. To repeat what I said in 1888 in a Note on valency especially as defined by Helmholtz (*Phil. Mag.*, 1888, [5], 25, 21), I do not hesitate to affirm that, from the chemical point of view, it is impossible to adopt the Helmholtz explanation of valency unless physicists are prepared to grant the possibility of the "division" of the unit charge. In the Paper in question, to explain my meaning, I developed what may be termed a skewer hypothesis of valency, desiring to give a graphic expression of chemical facts and thus help those who are not chemists to appreciate our position. Representing unit valency or charge by a single line, I postulated this line as capable of passing through the atom, and the atom as moving with more or less of freedom on the line. The union of two atoms was pictured as an overlapping of the unit lines. On this hypothesis, in cases in which the atoms do not move out to the end of their lines on combining, free ends would exist, by the overlapping of which combination between molecules could be brought about; and if it be supposed that hydrogen and the metals alone move freely on their lines, in order to give expression to the peculiar differences which apparently are manifest on contrasting the two classes of elements, the combination of a non-metal with a metal may be represented as involving the motion of the former alone out to the end of its line, leaving the line of the non-metal with a free end. In this manner expression may be given to what appears to be a fact—namely, that the non-metals condition the formation of molecular compounds.

What may be termed the *proper valency* of an atom—the number of atomic charges carried by, or of unit lines passing through, the atom—on this hypothesis is a function of the atom alone, whilst its *residual valency* in a compound is a complex function depending also on the atoms with which it is in association. This is well illustrated in the case of nitrogen by the behaviour of the amines—in all of which the nitrogen clearly functions as a triad—towards haloïds and acids, the extent to which basic characters are manifest depending in an extraordinary degree on the nature of the radicles associated with the nitrogen atom. Assuming that the proper valency of nitrogen is three, the formation of ammonium compounds from amines may be represented as due to the overlapping of the free end of the halogen line and that of one of the nitrogen lines: and if, in a case like that of the chloranilines, it be supposed that the effect of weighting the C_6H_5 radicle by introducing chlorine is to reduce the amount of free end of the nitrogen line to which it is attached, expression is given to the fact that the amine becomes less and less basic, and more particularly that the salt becomes less and less stable as each fresh atom of chlorine is introduced, length of overlap being regarded as the measure of affinity.

It may be asked why, on this hypothesis, if the nitrogen atom carries three atomic charges—is penetrated by three lines—it does not combine with three molecules of acid. Of course, at present no definite answer can be given, but, bearing in mind that the conviction is becoming more and more clearly established that affinity has direction and that geometrical considerations come into play, it is at least conceivable that the direction of two of the lines is such that their free ends perhaps meet, or that they are so directed towards each other that other lines are prevented from overlapping them. The introduction of some such conception would seem to be necessary to explain the remarkable behaviour of compounds such as nitrous oxide and diazoimide, N_3H, the inertness of which is most surprising, whatever view be taken of their constitution. Certainly, the difference between "unsaturated" nitrogen and "unsaturated" carbon which is manifest on contrasting these compounds with the olefines is most remarkable.

But it cannot be denied that, however possible it may be to "explain" the ammonium compounds on the assumption that nitrogen is but a triad, there are cases in which it is difficult to apply any such hypothesis as the above—one of the most striking being that afforded by the remarkable phenyliodonium compounds described by Hartmann and V. Meyer. It will scarcely be doubted by anyone, I imagine, that these and the equally remarkable iodoso-derivatives are not all to be regarded as proof that iodine is not merely a monad, but also a triad element—and yet it must not be forgotten that an iodine atom can combine with but a single hydrogen atom or methyl group, and that hydrogen and methyl are as yet the only trustworthy and, so to speak, legal standards by which the proper valency of an element can be measured. Even in such a case, therefore, a formula similar to that given to the ammonium compounds—viz., $C_6H_5{\cdot}I{\cdot}I{\cdot}C_6H_5$, cannot be put aside as absolutely out of the question; and if we bear in mind the peculiar character of the oxy-acids derived from the halogens, it is clear that much remains to be learnt of these elements. These acids are often quoted as arguments in favour of the view that the halogens are polyad elements, Mendeléeff having carried his poetic generalisations so far as to claim heptadicity for them; but even assuming that an oxide Cl_2O_7 exists, so long as we are unaware of its structure, we must remain unable to judge of the valency of its elements; we are certainly as little justified in assuming that it contains heptad chlorine as we should be in concluding from the existence of a compound of the formula C_6H_6 that carbon is a monad: valency is far too complex a function to be determined by a simple division method. It is not improbable that the oxy-acids in question are cycloïds.

The solubility of a substance such as triethylphenylammonium iodide in water, in which the amine and haloïd from which it is derived are so slightly soluble—and the fact that in the case of the ammonium salts of the chlorinated anilines above referred to hydrolysis of the salt takes place with increasing facility as the amine becomes less basic—may be referred to in further illustration of the difficulties to be overcome in formulating a consistent and sufficiently comprehensive theory of valency. On the hypothesis that such compounds are formed by the overlapping of the free ends of the lines of affinity, the compound should remain saturated or externally inactive so long as there was any overlap; on the other hand, if the somewhat more elastic atomic charge hypothesis be adopted, and it be supposed that any portion of the charge remaining unneutralised might be active, at least the case of the chloranilines would meet with an explanation.

But all these are matters of pure speculation, and I should not venture to allude to them, did I not feel that it is essential that now the amount of material at our disposal for discussion is so very large, it is time that some attempt were made to arrange it in such a form that the results won by chemists can be laid open to inspection by physicists and others capable of taking such transcendental questions into consideration. The theory of types and its logical outcome—the theory of bonds, have contributed in a remarkable manner to the progress of our science, and to these geometrical conceptions have now been added which are leading to further important developments; but it can only be supposed that such theories will all prove eventually to be of provisional value, and that far less mechanical conceptions must prevail.

Underlying all modern chemical inquiries there is an obvious desire to determine the structure of molecules generally, as well as to correlate structure with function; and most important advances in these directions have already been made. Whatever view we may hold, it is only too clear, however, that the conventional treatment of the subject involves the disregard of much that is of the highest importance; especially is it, perhaps, too commonly forgotten that whilst the determination of valency involves the knowledge of the structure of the compounds of elements whose valency is sought, the determination of structure is itself based on an assumed knowledge of valency. We are not only being led to frame the conception that affinity has direction, but also that its strength largely depends on the direction in which it is exercised (as shown by the very different behaviour and stability of cycloïds of different dimensions), and it is more than probable, therefore, that ere long we may formulate a theory in which the somewhat mechanical bonds to which we have become accustomed will give place to a more comprehensive hypothesis.

Faraday, in the paragraph previously quoted, regards both the hydrogen and oxygen in water as possessed of "residual affinity," and in his day, no doubt, there was no reason to draw any marked distinction between the two classes of elements—the metallic and non-metallic. But there is much in the behaviour of the latter which seems to me suggestive of the conclusion that they are the mainly active, attracting elements, and those, in fact, which condition chemical change; I venture to think that this will more generally be admitted to be the case than it is at present, when the facts are carefully considered. We have, it is true, long since abandoned the idea that only elements of opposite classes have considerable affinity for each other; but we are not yet advanced much beyond this, and have yet to recognise that the non-metals have very special mutual affinities.

It is in the play of these affinities more particularly that I am inclined to seek that conjoint influence to which I have frequently adverted by which electrolysis, and therefore change is, it seems to me, brought about. The force of the objection made to this explanation that there are no appreciable reverse electromotive forces within an electrolyte may easily be overestimated. Adverting to what was said above with reference to the phenomena involved in charging a condenser, if any similar effect were produced in a fluid electrolyte—if any internal polarisation were set up—it would at once be discharged; and such polarisation would

Digitized by Google

be imperceptible, just as in the case of the determination of conductivity by an alternating current method. A considerable amount of work might, therefore, be done by the current unperceived, and the forces might well be enormous even within the liquid (compare Lodge, *Brit. Assoc. Report*, 1890, 330). I am loth to believe also that the low values found for "ionic velocities" are in truth the velocities of the ions, and would prefer to regard them as but differences between values of which at present we have no conception.

A similar argument will apply in the case of osmotic pressure phenomena, and therefore generally in explanation of the regularities observed in the case of dilute solutions. To say that the osmotic pressure is due to the dissolved substance alone, appears to me to be but a useful figure of speech—in reality, the phenomena must be due to both solvent and dissolved substance. Although one attracts the other, however, the unions are probably but temporary, and the opportunities given for exchanges to take place are so infinitely numerous that the dissolved substance behaves practically as an almost perfect gas. From this point of view it is also not remarkable even that the pressure should have the same value as it would have if the substance were gasified, for, inasmuch as the molecules of the dissolved substance are kept apart by those of the solvent, they are practically in the gaseous condition.

As regards the superior effects produced by electrolytes, I would repeat what I said at Leeds in 1890 (*Brit. Assoc. Report*, p. 326), that, having been able by observations of electrical conductivity, as well as by other methods, to classify electrolytes in the order of their activity, we are now in a position to apply the correction required to discount the superior effects produced by such compounds in comparison with dielectrics. Why they are specially active the future must decide. To me it seems that their activity is attributable to their special composition and structure—particularly to the presence in them of either oxygen or halogen in an eminently unsaturated condition, and possessed, therefore, of considerable residual affinity.

As regards semi-permeable membranes, as they have been called, I imagine we have yet much to learn in explanation of these. That the membranes through which liquid diffusion takes place cannot be mere sieves there is hardly a doubt, otherwise it would scarcely happen that gases only diffuse through septa consisting of materials in which they are soluble: as illustrated by the diffusion of oxygen through caoutchouc and silver, of carbonic oxide through iron, and of hydrogen through platinum and palladium.

In the case of colloïd membranes, through which so many crystalloïds pass, everything seems to depend on the peculiar relationship of water to such matters—a relationship which is so apparent in many physiological phenomena—and at the same time of water to crystalloïds.

The foregoing may be said to be an essay in advocacy of a theory of *association* in explanation of chemical change, as opposed to one of *dissociation*. The attempt has been made to show that such a theory is of universal application, whilst the dissociation hypothesis is apparently not only of limited application, but in some cases irreconcilable with the facts. It also involves assumptions which it is difficult for the chemist to grant: I allude particularly to the main article of faith in the dissociationists' creed that a certain very limited class of compounds—electrolytes—fall to pieces, as it were, more or less completely on entering into solution. As I have implied over and over again, such an assumption necessitates a profound distinction being made between electrolytes and other compound molecules generally which is not patent to the unprejudiced observer, and for which no motive or reason whatever can be assigned. It must not be forgotten that Clerk Maxwell was led by reasons of this very kind to remark that chemical combination is a process of a higher order of complexity than any purely electrical phenomenon.

I have sought also to make clear the great importance of the part played by "impurity" in Nature in conditioning chemical change—a part which seems to meet with an explanation from the association, but not from the opposite point of view. The influence of impurities on properties has also been specially noted.

Lastly, the insight which the study of the electrical behaviour of substances generally promises to throw on almost all of the chief problems of chemistry has been briefly touched on.

I am only too conscious that my discussion of all these questions is not only incomplete, but very general and even vague in many places, language being sometimes used—as in quoting from Faraday—in a sense which may somewhat offend the purist; probably, however, the object I have in view will be clear even in these cases.

THE CHELTENHAM ACCIDENT.

The following is Major Cardew's Report on the fatal accident which happened on December 16, 1895, to John Pugh, mechanic, employed in carrying out some alterations in one of the transforming chambers used by the Corporation for the purposes of electric light supply. The Inquiry was held on the 15th ult., and the following witnesses were examined:—

Leicester Richards Lee (Engineer), Richard Edwards (Jointer), M. H. Kilgour (Borough Electrical Engineer), and Richard Cresswell, D.Ph. (Surgeon).

Account of Accident.

The circumstances of the case, says the Inspector, were as follows:—

The Corporation of Cheltenham supply electric energy by means of a high-pressure alternating current, at a constant pressure of 2,000 volts, which is reduced by means of transformers placed partly in transforming stations below the level of the street and partly on consumers' premises, to a pressure of 100 volts, for purposes of supply to consumers. The transforming stations are larger than those usually constructed for the purpose, and are in all respects suitable in construction. The arrangements within them consist, in addition to the transformers, of high-pressure and low-pressure switchboards for regulating purposes. The particular station in question contains an extra number of high-pressure switches, as from it is controlled the supply to another transforming station.

The work upon which the party were engaged at the time of the accident was the erection of a low-pressure switchboard on the north wall, in a position closely adjacent to one of the high-pressure switchboards. The unfortunate man was at the time boring a hole in a wooden batten with a large gimlet at a distance of only about four inches from the high-pressure switchboard, on which were fixed several switches with exposed metal surfaces, charged to the full pressure of 2,000 volts.

The conditions, in fact, were such that, although it was possible to do the work without making contact with the charged metal, it required continual care and attention to avoid the fatal consequence of an unguarded movement. The danger was, I consider, almost equal to that of sending a man into a magazine full of loose powder with a lighted candle in his hand.

From the evidence of the foreman under whom Pugh was employed it appears that the latter was decidedly careless by nature, and that before the accident happened he had been cautioned several times. An india-rubber mat had been provided as a protection to be used when working at the high-pressure switchboards, but had been moved away, probably by the men at work, as not being required since they were not manipulating the electric circuits. India-rubber gloves were also provided, but the use of these would certainly have been inconvenient.

The accident appears to have been caused by Pugh, in a moment of forgetfulness, raising his left arm until it came, as it naturally would, into contact with the charged metal in two places, causing wounds as described by Dr. Cresswell, the current entering his body by this arm, and leaving it partly by his feet and partly by his right hand, assuming that he was grasping the gimlet at the time. The abrasions on the face were probably caused in his fall, either by a simple blow or a subsequent contact. Death appears to have been practically instantaneous.

Opinion and Recommendations.

In my opinion this accident is chiefly to be attributed to an error in judgment on the part of those responsible in allowing such work to be carried on in close proximity to highly-charged metal. It is too much to expect that any man, and especially an imperfectly educated man, should exercise such continual care over all the movements of his body as was necessary in this case when he is engaged upon work distracting his attention from the danger, and when the danger itself is not of a kind that appeals to the ordinary senses.

I understand that had the electric pressure been switched off from the sub-station to enable the work to be done with safety, the supply to a few customers would have been interfered with to some extent. I ascertained, however, that the Undertakers regularly stop supply altogether on Wednesdays for two hours in the middle of the day, and the work could have been carried out with absolute safety during this interval. The fact appears to be that the possibility of danger was unfortunately overlooked.

Under ordinary conditions no work other than attention to the electrical circuits should be carried on in any transforming station when any apparatus contained therein is charged to a high pressure.

In the second place, I consider that the switching arrangements on the high-pressure switchboards in use in this and other transforming stations are needlessly dangerous in that large surfaces of charged metal are exposed, which could easily be covered by solid insulating material, so as to render an accidental contact with them impossible.

I was pleased to find that on the main switchboard at the generating station, well-designed arrangements had been made for the guarding of all charged metal. Some similar arrangements should be carried out on the switchboards in the transforming stations. The necessity for some alteration in this respect is now fully recognised by the Borough Electrical Engineer, who had prepared for my inspection a model of an insulating cap to partially cover the charged metal. It appeared to me, however, that the protection could be made more complete, and my suggestions are now, I understand, under consideration.

Thirdly, I would suggest that in all the transforming stations a thoroughly insulated floor should be provided, as can easily be done at a small expense. The indiarubber mats at present used are probably effective, but they are

Digitized by Google

easily displaced. They should be retained for use on the insulated floor as an additional precaution.

There should also be in every case where it can be arranged a stout wooden rail or other division to separate off the portion of the chamber in which high-pressure apparatus is fixed.

Finally, the Board of Trade should, I consider, request the immediate attention of the Corporation of Cheltenham to the remarks and suggestions contained in this report. Those who undertake the supply of electrical energy at a pressure which involves the danger of sudden death from a cause so unnatural and so remote from human experience as the mere contact with a piece of metal, and who in their operations necessarily employ men of imperfect education, untrained to grasp abstract ideas, have a heavy moral responsibility for the safety of their employés. I feel confident that the Corporation of Cheltenham and their electrical engineer fully realise their responsibilities in this matter, and that they will spare no expense or exertion to prevent for the future any accident to their employés.

THE LONDON COUNTY COUNCIL AND THE OVERHEAD TROLLEY SYSTEM.

At the weekly meeting of the London County Council, held at the County Hall, Spring Gardens, on Tuesday, the Parliamentary Committee reported having considered the London United Tramways Provisional Order. By the Order it was sought to exempt the Company from the provisions of the London Overhead Wires Act, 1891, and the bye-laws made under the Act, and to authorise the Company with the consent of the Council to place overhead wires for working the tramways by electrical or other mechanical power, including the overhead trolley system of electric traction or any other system. The Council twice last year refused its consent to the use by this Company of electric traction by means of overhead wires, and having been informed by the Highways Committee that in their opinion the granting of the Order should be opposed, they recommended "That the Council do refuse its consent to a Provisional Order being granted to the London United Tramway Company."

Earl RUSSELL said the Committee, in their preamble to the recommendation, said that the Council twice last year refused its consent to the use by the Company of electrical traction by overhead wires, and the Highways Committee's ground of refusal was that the Council had never consented to overhead wires. London was peculiar in not using the trolley system in traction. He thought they should be informed whether it would interfere with the traffic in the streets in which it was proposed to use it. The order as it stood was perhaps one they could not agree to because it gave power to the Company, with the consent of the London County Council, to maintain those overhead wires in any part of their system. The system as extended at present did not come nearer than Shepherd's Bush, and he thought it most probable that along the whole of its present length the system of overhead traction could be used without inconvenience. Of course, the Council could hardly consent to give them power to introduce over head traction into Oxford-street, and he did not propose that. All he asked the Council to do was to exercise its common sense in the matter. Those who had seen the thing at work or had seen illustrations must know that it caused no real eyesore in the streets. He would go further and say even if it did cause some slight æsthetic eyesore in the streets it was no reason why they should deny the benefits of easy transit to those who required it. People wished to get about their business rapidly and cheaply, and he ventured to say on behalf of the persons who used tramways that they did not care about a wire more or less in the streets. The Overhead Wire Act was never intended to apply to a tramway company. It was intended to preserve them from the existence in the streets of numerous unused wires, the supports of which were never examined and were consequently liable to fall at any moment. It was never intended to be a matter of general principle. He appealed to the Council to refer the matter back in order that it might be considered on its actual merits and to see whether they could not allow in particular instances overhead wires to be used.

Mr. THOMPSON seconded the amendment.

Mr. ROBERTS said it was a matter debated very much in the old Council, and they were almost unanimous in deciding that overhead wires were not desirable. He thought they ought to consider the matter not only with a view of cheapness, but with the view of those who really had some interest in the beauty of London. He even believed that in the view of economy it was not desirable to deface their thoroughfares in that way. The Company was only anxious to have overhead wires so that they could do the work cheaply—it was not so much a question of the convenience of the public as of dividend paying. The desire of the people who promoted those companies was of course to reduce the initial cost, and it was the duty of the County Council to stand out for the interests of the people as a whole. If they put those hindrances in the way of the Company they would get some more economical and perhaps better method of locomotion in London without defacing the streets. He asked the Council to make a bold stand at once and say they would have nothing to do with any such thing.

Mr. JOHN BURNS, M.P., said he had seen the overhead tramways in Leeds and in Boston and other cities, and he ventured to say, whatever the opinion of the Council might be with regard to the introduction of the overhead trolley system in London, the Houses of Parliament would not have it. If they allowed it to be introduced at Shepherd's Bush, they could not deny it to Kensington, and then they must at last allow it in the Mall and over their bridges. Did Earl Russell say that should be done? If Earl Russell would go down Brixton-road what would he see? He would see what he (Mr. Burns) considered one of the finest constructed tramways in the world. It was a cable tramway. He hoped that the proposal to introduce the American monstrosity of overhead wires would not be allowed.

Mr. J. WHITE said he was not an æsthetic, and he confessed that he had seen the tramways at work in Bristol and in Brussels, and saw nothing to offend the taste of average man. His friends Mr. Roberts and Mr. Burns were far above the average in æsthetic taste, and he asked the Council not to legislate for their high-toned notions, but to bring themselves down to the common sense standard which must govern the community. He could see no harm in the matter going back to be reconsidered by the Committee. The only reason at present given of refusal was that the Council had never done such a thing before, but if the Committee would give them some material reason why the thing should not be allowed, they (the Council) could be far better judges than they were now.

Mr. MCKINNON WOOD (Chairman of the Parliamentary Committee) said that the Committee simply moved on the recommendation of the Highways Committee, who were experts and were responsible. It was not, however, a mere question of the remote suburbs, but other roads might be disfigured by that particular form of electrical traction if the Order were approved, because the Company took powers to introduce the overhead wires in any part of their system, and that included the Uxbridge-road and the Hammersmith-road.

The amendment was then put and defeated in a somewhat small Council, and the recommendation was carried.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-day) FRIDAY, February 21st.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Students' Meeting. Paper to be read: "Some Central Station Experience," by W. Fennell.

SATURDAY, February 22nd.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "Light," by the Right Hon. Lord Rayleigh.

MONDAY, February 24th.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture II.: "The Chemistry of Certain Metals and their Compounds used in Building, and the Changes produced in them by Air, Moisture, and Noxious Gases, &c.," by Prof. J. M. Thomson.

NORTHERN SOCIETY OF ELECTRICAL ENGINEERS.

8 p.m. General Meeting at the Palatine Hotel, Hunt's Bank, Manchester. Paper to be read: "The Development of Electric Lighting Engines," by H. Lindley.

TUESDAY, February 25th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be discussed: "The Electric Street Railway System of Montreal, Canada," by G. C. Cuningham.

THURSDAY, February 27th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary Meeting. Conclusion of discussion on the following Papers: (1) "The Electric Wiring Question," by F. Bathurst. (2) "Concentric Wiring," by Sam Mavor. Paper to be read: "High-Voltage Lamps and their Influence on Central Station Practice," by G. L. Addenbrooke.

FRIDAY, February 28th.

PHYSICAL SOCIETY.

5 p.m. Meeting at Burlington House. Papers to be read: (1) "Experiments with Incandescent Lamps," by Sir D. Salomons. (2) "On the Alternating Current Arc," by Dr. Fleming and Mr. Petavel.

ELECTRO-HARMONIC SOCIETY.

8 p.m. Concert (Ladies' Night) at the St. James's Hall Restaurant.

SATURDAY, February 29th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "Light," by the Right Hon. Lord Rayleigh, F.R.S.

The Electrician.

The Oldest Electrical Journal (1861—1878.)

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny
Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone No. 6949. *Telegrams:* "ELECTRICIAN NEWSPAPER LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*"

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The Rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	Year.	Half-Year.	Quarter.
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.

(Post free, payable in advance.)

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to* 4 *p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. FLEMING, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Vol. I. Price 12s. 6d., post free 13s. *Vol. II. is in preparation.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.
VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free, 8s.
VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. 93 original illustrations, handsomely bound. price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. SNELL. 10s. 6d.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free 8s.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d. net, post free, 13s., abroad, 13s. 6d.

"THE ELECTRICIAN" PRIMERS. In Two Volumes. Price: Stout paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

THE WORK OF HERTZ. By Dr. O. J. LODGE. Price 2s. 6d.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*In preparation.*

THE RENAISSANCE OF SUPERHEATING.

The *renaissance* of superheating in steam practice, which has occurred within the last few years in this country and somewhat earlier on the Continent, promises to place the use of superheated steam upon a more firm and lasting footing than was the case when it was invented and first used in the time of TREVITHICK. For not only have thermodynamic theory and actual practical trial shown conclusively that this form of steam can produce more economical results in a steam engine than ordinary saturated steam can do, but the improvements in the manufacture of iron and steel and a better knowledge of boiler design enable superheaters to be built which do not possess the defects which rendered the pioneer superheaters such a failure. Among those whose interests are affected by any question, such as steam superheating, relating to steam engine economy, electrical engineers may claim one of the foremost places, at any rate as regards stationary engine practice. Indeed, the competition in which they have been placed with other modes of producing light and power, has compelled electrical engineers to turn their attention to every possible source of increased economy in their plant, and thus has forced them to take a lead in the modern improvement of the stationary steam engine. To them, therefore, the "Notes on Steam Superheating," recently read by Mr. W. H. PATCHELL before the Institution of Mechanical Engineers, will be of interest. We commence this week a reprint of this valuable and comprehensive Paper, in which the author has not only published his own personal and lengthy experience of the use of superheaters at the supply station of the Charing Cross and Strand Electricity Supply Corporation, but has drawn up what might be termed a critical history of superheaters and superheating, enriching it with details of numerous trials.

The practical advantages in the use of a superheater appear to arrange themselves under three heads—firstly, the steam is less damaged during its passage from the boiler to the engine; secondly, each pound of steam in the engine will do more work than if it had not been superheated; and thirdly, the boiler may, in certain cases, be made to generate a

Digitized by Google

greater number of pounds of steam when steaming at its maximum rate. These three points are well brought out in Mr. PATCHELL's Paper. In order to understand the first of these three advantages it will be necessary to consider the second as a preliminary. Steam which leaves the boiler in a superheated condition, and passes through a system of pipes to an engine, will do more work in the engine than if it had not been superheated, *even when it does not reach the engine in a superheated state.* It is well attested by almost countless trials that this is the case, and the explanation is to be found in the fact that if steam has once been superheated it will reach the engine with a lower percentage of wetness than if it leaves the boiler merely as saturated steam. Now, wetness in steam seems to have the power, as it were, of feloniously inciting to further wetness immediately the steam enters the cylinder. If the steam is dry or only slightly wet the cylinder condensation will be small, but if there is a larger percentage of wetness the initial condensation will be altogether out of proportion to the additional wetness. A high degree of wetness, therefore, will develop a ruinously large amount of initial condensation, from 50 to 70 per cent. of the actual steam in the wet mixture being precipitated immediately upon its entry into the engine. It will be seen, then, that something by no means inconsiderable will have been done towards improving the economy, if the steam is brought to the engine, a little drier, even though it may not arrive there actually superheated. Of course, it will be better still if the steam is not only dry but possessed of actual superheat, for then it will carry with it right into the cylinder surplus heat which will arrest the cooling action of the walls. With these facts in mind, it will not be difficult to understand that the addition of a superheater to a boiler plant enables the steam pipes to convey the steam to the engine in a less damaged condition. We do not mean that there will be less radiation and conduction of heat; indeed, there will be more, for the steam will be hotter. What we do mean is, that this loss of heat will not injure the steam to the same extent that it would—or that even a lower loss would—if the steam were not previously forearmed against the generation of wetness. For, let it be remembered, not all of the water which arrives at the engine arises from priming in the boiler; most, sometimes all, of it is caused by cooling of the steam as it passes through the pipes. Superheating allows this cooling to occur without the formation of water.

With regard to the third advantage attending the use of a superheater there may be differences of opinion. Mr. PATCHELL has shown that in the case of one of the water-tube boilers at the supply station under his control the steaming capacity was raised from 3,457lb. per hour to 8,293lb. per hour, a matter of 140 per cent., by the aid of a superheater and extra draught; and at the end of the reading of his Paper he stated that a stoker under his charge had managed to get 10,125lb. per hour from this boiler, or nearly treble the normal maximum. In so far as this improvement was due to the superheater, it only shows that without the superheater there would have been wet steam, due to priming. If a superheater is supplied with dry steam it cannot possibly increase the gross output of steam from the boiler; and that it does so in any case is a proof that the boiler to which it has been fitted is liable to prime. We do not believe that any such alteration in the steaming capacity of a good Lancashire boiler would result from the addition of a superheater; and we may add that, indirectly, Mr. PATCHELL's figures are a further interesting testimony to the inadequacy of the ordinary water-tube type of boiler where heavy forcing is to take place. On the other hand, it is a very useful fact that the addition of a superheater to a battery of boilers liable to prime heavily when forced will turn all the primed water into good steam; though it may be doubted if this practice is altogether fair to the superheater.

Against the undisputed advantages of superheating, however, there are some disadvantages which it will be necessary to consider. These may be met with, firstly, in the apparatus used for superheating the steam, and, secondly, in the use of superheated steam in the engine. In order that the superheating surface shall be efficient it must be exposed to furnace gases at a much higher temperature than the steam. This will render it necessary either to have an independent firing arrangement, which may be shut off in the event of anything going wrong, or else that the superheater be placed in a very early part of the main flues of the boiler. In the latter case the superheater is subjected to conditions which intensify the risk of breakdown and, at the same time, render a breakdown disastrous and difficult to repair. It was this very consideration, we believe, which led Prof. KENNEDY to place the superheaters at the Edinburgh Supply Station in a later part of the flues, where, however, they could not be very efficient nor possess much regulating power. One of the speakers who took part in the discussion on Mr. PATCHELL's Paper expressed his opinion that a superheater was merely an extension of the boiler. Now, it is precisely in the contrary to this statement, and in the radical distinction between a superheating surface and an evaporating surface, that the principal trouble with the former will be found to exist. A true boiler surface will have furnace gases on one side of it and water on the other side, and danger arises the moment the water is replaced by steam through fall in the water level. A true superheater surface will have furnace gases on one side of it and steam on the other side; but in practice it often has both steam and douches of primed water on that side at which there ought to be only steam. No boiler maker would dream of constructing a boiler, as such, in which the evaporative surfaces would be exposed to the conditions which every superheating surface must withstand; and it is in this fact, as we have already stated, that the risk of breakdown of superheaters lies.

The troubles in the engine itself attendant on the use of superheated steam do not appear to be so formidable at the present day as they were in earlier times. One of the reasons assigned for the former abandonment of the practice was the injury which the superheated steam inflicted upon the valve faces, cylinder liner and glands of the engine. Yet neither the pressure of the steam nor the number of degrees of superheat approached present-day practice. Part of the ancient troubles no doubt arose from the use of vegetable and animal fats and oils for lubrication, which at the temperature of the steam liberated acids which attacked the metal of the engine. The use of mineral oils nowadays obviates any such difficulty. Another cause, probably, was the inferior quality of the metal used, whether for the cylinder or for the glands. There is also much reason in the hypothesis put forward by Mr. PATCHELL, that while superheated steam itself may not be injurious, the alternation of it with wet steam, exposing the surface now to the one now to the other, will cause pitting and cutting of the surface. And it is a very excellent argument against the intrinsic power of hot, dry steam to injure a metal surface, that in a gas engine such surfaces are exposed with impunity to gases very much hotter than the hottest superheated steam that ever has been used. On the other hand, we must not forget that in the majority of cases where superheaters are used the steam never enters the engine in a superheated condition. Even where it arrives at the engine stop valve in that

Digitized by Google

state, its admission into the engine will generally be accompanied by so rapid an abstraction of heat by the cylinder walls that it swiftly changes into wet steam. Nor, during this change, will it be likely that the metal will be brought into contact with the dry steam, for the inevitable film of moisture on the surface of the metal will prevent this. Only where the degree of superheat is very considerable can it be expected that the cylinder liner will come into touch with really dry and superheated steam.

On the whole, then, the numerous advantages of superheating outweigh its possible disadvantages; and it seems probable that we are on the eve of a very considerable extension of the use of superheaters in stationary engine practice. The results obtained at the Maiden-lane station, and given in detail by Mr. PATCHELL, show that the modern superheater has stood the test not merely of short trials under test conditions, but that as an everyday adjunct to a battery of boilers it is reliable and economical. Its extensive use on the Continent at the present time, as well as the excellent results which have been achieved with it in connection with the Parsons steam turbine, are further evidence that the *renaissance* of superheating is not a fitful splutter but a permanent revival.

ON THE PRODUCTION OF ELECTRIC PHENOMENA BY MEANS OF ROENTGEN'S RAYS.*

BY PROF. AUGUSTO RIGHI.

1. It is noticed that the most salient properties of the X-rays, and especially the property of exciting fluorescence, and that of acting on photographic plates (which Röntgen suspects to be a secondary effect arising from the former) belong, moreover, in especial manner, to the less refrangible of the ordinary light rays. Since the latter are equally highly suitable to generate photo-electric phenomena, I have wished to investigate whether phenomena of this kind can also be produced from the X-rays.

As my investigation, although hardly begun, has borne fruit, I am at once communicating to the Academy the results obtained. But for the sake of clearness it is necessary to preface a brief remark on photo-electric phenomena in general.

2. A negatively electrified body rapidly loses its charge if it is exposed to radiation. According to the nature of the body and to the wave-length of the radiation used, the rate of dispersion of the charge is less or greater, whilst in the case of the greater number of bodies the phenomenon is produced only by having recourse to the rays of the smallest wave-length given out by the voltaic arc (and especially from that produced from carbon and zinc or aluminium), or even those given out by magnesium in combustion; for some bodies, such as amalgamated zinc, even sunlight is useful, and for others, like the alkaline metals, the most ordinary artificial light.

I should here mention particularly an experimental arrangement, that of the *photo-electric couple*.† A metal disc receives the active radiations after they have passed through a piece of metal gauze parallel with and close to it, and communicating with the earth. The radiations, in dissipating the negative charge, which (by the effect of the contact difference of potential) either the gauze or the disc possesses (the same having an instant before the experiment been put into metallic communication), cause a positive or negative deviation according to circumstances in an electrometer, communicating with the disc, and which gives sensibly the measure of that difference of potential.‡

If, in repeating the experiment several times, the disc is placed further and further from the gauze, the deviation augments in value if positive, and diminishes or is brought to zero and reversed if negative.

The immediate cause of this effect is a phenomenon shown at the end of my first researches on the electric phenomena of radiation, viz., that by virtue of which a discharged body charges itself positively when it is exposed to radiation.*

This phenomenon obeys a law which I have established by many experiments, and which may be enunciated thus: When the positive charge of the body which receives the radiations stops increasing, then the electric density has reached a certain value, constant for all given substances.

It follows from this law that the positive deviation, produced by the radiations, becomes smaller and smaller, if the body which receives the radiations approaches more and more nearly to a conductor communicating with the earth which does not increase the capacity. In order to show the positive charge generated by the radiations it is then needful that the body on which we are acting should not be too near to uninsulated conductors. In the opposite case—that is, that of the photo-electric couple—the generation of that final positive charge has no influence whatever on the deviation obtained.

3. In order to examine whether the X-rays also cause the dispersion of the charge of a negatively-electrified body, and whether they charge positively a non-electrified body, I have operated with methods similar to those now described, as follows:—

1st. I have given a charge of any amount whatever to a conductor, and then I have examined its potential, as indicated on a quadrant electrometer communicating with it, as to whether, when the X-rays fell upon it, it underwent a diminution more rapid than that proceeding from the usual loss of charge.

2nd. I have made the X-rays fall upon a photo-electric couple, and have observed whether they cause a deviation in the electrometer communicating with the disc, the gauze being in communication with the earth.

3rd. I have examined whether the same rays falling on a non-electrified body produce in it an electric charge.

In setting up a suitable experimental arrangement I have been obliged above all to do it in such a way that no doubt can exist as to there being any electric action whatsoever produced directly on the electrometer or on the bodies communicating with it by the apparatus generating the X-rays.

Therefore I placed the Crookes tube, together with the coil, the interruptor, &c., inside a large metal case communicating with the earth. One of the side walls of the case is composed for the most part of a thick sheet of lead furnished with a circular window, in front of which and inside at a little distance is that part of the Crookes tube which is struck by the cathode rays.

The window can at pleasure be closed either by a thick sheet of lead or by a very thin plate of aluminium. In either way, when the apparatus contained in the case is in action, no electric force whatever which proceeds directly from the internal charge to the case shows itself on the outside.

But when I placed conductors, electrified or not, in front of the window closed with aluminium, I observed the following phenomena:—

4. If a conductor charged negatively has just been placed in front of the window, the Crookes tube has hardly entered into action when the charge rapidly disappears.

If the conductor is non-electrified it electrifies itself positively, and by equality of conditions the final potential is different according to its nature—for example, greater for retort carbon than for copper; greater for copper than for zinc.

With this last metal the deviation is negative when the distance between it and the aluminium is small enough. This occurs because of the contact difference of potential, but at greater distances the positive charge produced by the X-rays prevails.

Finally, if a photo-electric couple is placed before the window, a deviation in the electrometer is obtained similar to that produced by ultra-violet radiations.

I have not yet been able to examine if this deviation is exactly equal to that which the latter species of radiations

* From the Proceedings of the R. Accademia delle Scienze dell' Istituto di Bologna.

Digitized by Google

will cause. In actual experiment one may dispense with giving to one of the metals of the couple the form of gauze, seeing that thin metal plates, especially of aluminium, allow the X-rays to pass through. So one may substitute for the gauze a thin plate of that metal.

Consequently I can say: *The X-rays have, in common with the ultra-violet rays, the power of determining the dispersion of the negative charge, and of giving rise to a positive charge in non-electrified bodies.*

As was to be foreseen, the electric action of the X-rays diminishes if the bodies on which they act are removed further from the window whence the rays proceed.

Placing against the window a thick slab of pinewood, or a sheet of aluminium, or a sheet of glass, or the hand (placed in such a way as to entirely cover the window), &c., diminishes more or less the effect produced by the X-rays, but in general does not completely eclipse it. In particular it is noted that plate-glass less than a centimetre thick is more absorbent than pine-wood six centimetres thick.

5. The ultra-violet radiations do not produce a sensible action on positively-electrified bodies, since if in any case they seem to cause the dispersion of the positive charge, it can be recognised that the effect observed was due to the dispersion of the negative charge of the surrounding bodies.

Well, now, having given a positive charge to the conductor (retort carbon, copper, zinc, &c.), on which the X-rays fall, I observed the same action as in the case of the negative charge. Therefore: *The X-rays, unlike the ultra-violet rays, cause dispersion also from positively-electrified bodies.*

Naturally, whilst in the case of the initial positive charge the dispersion ceases when there remains in the conductor a charge equal to that which, when it has returned to its natural state, the rays have caused it to acquire, in the case of the initial negative charge the dispersion continues until the body is discharged; and then the process is resumed until it has produced the same final result that it had when the initial charge was zero or positive. This result can be explained by saying that the conductor communicating with the electrometer seems to behave like an exploring electrode immersed in a conducting medium, and which assumes the potential proper to the place it occupies, whatever be its initial potential. Under equal conditions I have not recognised, at least on first examination, any noteworthy difference in the rate of dispersion, according to the sign of the charge, in the bodies on which the vibrations fall. The phenomenon can also be observed two metres and more away from the window.

6. It is important to take note how the new properties here established are valuable as furnishing a means of measurement by the X-rays. I believe that any one wishing, for example, to compare the absorptions of various bodies, will prefer to express numerically these absorptions on the basis of the variations of the rate of electric dispersion rather than be contented with the approximation based on a comparison of the intensity of a shadow projected on a fluorescent screen or on a photographic plate.

Evidently these new properties should be kept in remembrance when the time shall arrive for discussing the various hypotheses proposed to explain the nature of the X-rays.

7. I have prepared a lecture experiment to show the dispersion of charge caused by the Röntgen rays. In this case I have dispensed with the metal case, preserving only the large sheet of lead with the window closed by aluminium. A disc of any kind of metal is placed at a few decimetres distant from the window at one side of the sheet of lead, whilst at the other side of it is the Crookes tube with the apparatus which excites it. The disc communicates with a gold-leaf electroscope. The insulation being good, a charge of either sign is given to the apparatus—for example, by a dry pile; the leaves remain for a long time motionless and diverging, but hardly has the Crookes tube entered into action, they fall down and remain vertical.

As soon as I close the aperture with a thick sheet of lead, the phenomenon ceases to be produced. If, instead, I place against the window other bodies such as the hand, or wood, &c., a mere slowing of the falling of the gold leaves is observed.

THE "SPERRY" STEAM ENGINE.

An account of a remarkable steam engine, designed by Mr. E. A. Sperry, is published in a recent issue of the *Electrical Engineer* of New York. So far as we can gather, the engine has not yet actually been built; but in the elements of its design it calls for some notice. These elements are not in themselves novel, though their combination and the purposes which they serve appear strikingly original. Before describing this engine it will be well to review the chief considerations which led Mr. Sperry to design it. The objects he sought to attain were: a high-speed dynamo driven by a slow-speed steam engine without gearing. What at the first glance may appear impossible of solution he has readily accomplished by means of link motion. This is, in fact, by no means the first instance of the application to linkages in engines for transforming reciprocating motion. Mr. Atkinson, in his famous "Cycle" gas engine, used a toggle arrangement of links for the purpose of causing four strokes of the piston to occupy the time of one revolution of the engine pulley. But in this gas engine the lengths of the four strokes were all different. Mr. Sperry has reversed the application of the toggle which Mr. Atkinson made, and has used it to produce two

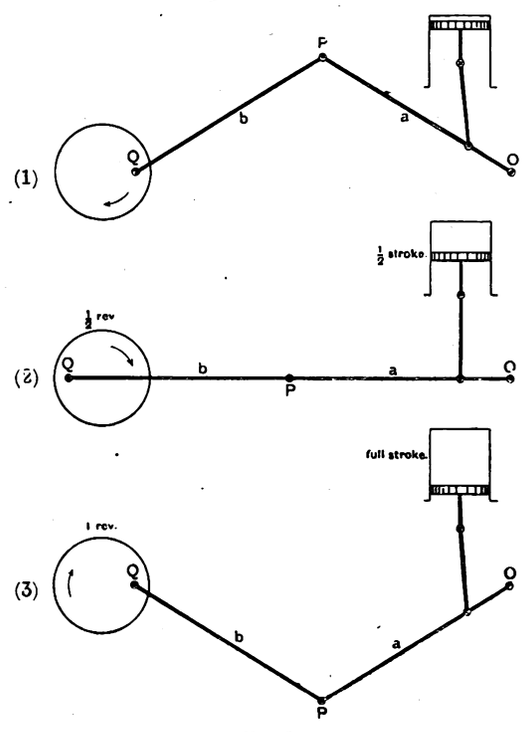

FIG. 1.

revolutions of the engine (and dynamo) shaft during the period of one double stroke of the engine piston, with the further modification that the engine strokes are all of equal lengths.

The main principle of the mechanism, by which the speed is increased in the "Sperry" engine, may be understood by reference to Fig. 1, which represents diagrammatically the several stages of one stroke of the engine. The piston rod is connected by its connecting rod to a point on a link *a*, which has a fixed pivot at O, and which is at P coupled to one end of another link *b*. The further end of this second link *b* is coupled to a disc crank on the dynamo shaft. In position (1) the piston is about to commence a down stroke. In position (2) the first half of this stroke is completed, and the extension of the toggle, composed of the links *a* and *b*, has produced a half-revolution in the crank Q. In position (3) the stroke is completed, and at the same moment the crank has also completed one revolution. During the return stroke of the piston another complete revolution will be effected, thus making two revolutions in the time of a double stroke. It will be noticed that by varying the lengths of the links *a* and

Digitized by Google

b, or by altering the point of attachment of the connecting rod to the link *a*, a wide range in the ratio between the length of the piston stroke and the throw of the crank Q can be obtained, a matter which will be of some practical importance in balancing an engine of this type.

Such a design as the one under present consideration offers many interesting problems to the engine builder. Of these we may notice two which will always be of prime importance—viz., balancing against reciprocating reactions, and the provision of sufficient inertia to prevent undue irregularity of speed in the dynamo shaft. In regard to the first of these, the balancing of reciprocating actions in such an engine will be a more complicated and difficult matter than in an engine of the ordinary type, firstly because of the greater number of parts thrown into reciprocating motion, and secondly because both the transverse and the axial reciprocating forces will be greater than in an engine of ordinary type. Lack of careful balance would be liable to develop excessive vibration and shock, or pounding, in an engine of the "Sperry" type. In the actual engine it is proposed to use counterweights on the toggle, as well as to proportion the mass of the links to their speed and the stress to which they would be subjected. Fig. 2 gives a diagrammatic representation of the toggle with counterweights at A and B. These counterweights, properly proportioned and placed in suitable parts of the link motion, will not only serve to balance the parts, but may also be used in place of a flywheel to equalise the driving effort on the dynamo crankshaft. The counterweights will have an approximately simple harmonic motion, and during the first half of their swing will accumulate energy which they will restore during the second half. It may here be pointed out that the whole of the energy accumulated by them is restored, whereas in a revolving flywheel it is only a very small proportion of the total accumulated energy which

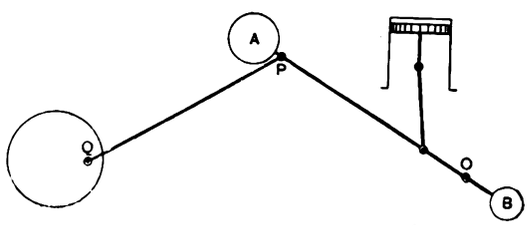

FIG. 2.

flows out of the wheel during each revolution. In other words, the accumulating efficiency of 1 ton of metal is much higher in a reciprocating mass that in a flywheel which may fluctuate only 1 or 2 per cent. in speed. As an illustration of this, Mr. Sperry takes the case of a 400 H.P. engine, making 100 double strokes and 200 revolutions per minute. The maximum velocity of the joint P (Fig. 1) in this engine is 52ft. per second, and occurs once during each revolution. One ton of metal located at this point would have an accumulated energy of 165·6 horse-power seconds, which it would liberate during the next half-stroke of the piston. It is clear that this, if well distributed, might be utilised to equalise the varying effort of the steam in the cylinder.

Practical experience is the final court of appeal in deciding the merits of such an invention. Yet it may be permitted, even at this stage, to doubt whether Mr. Sperry's ingenious invention possesses any advantage over more than one well-established method of driving a dynamo. The use of a slow-speed engine with Corliss gear may or may not be, in itself, more economical than a high-speed engine; but we feel sure that any economical superiority it may possess would be swallowed up in the extra frictional losses of the added link motion. Nor can we believe that this link motion would be found to possess a mechanical efficiency any higher than a simple belt or rope drive. To establish the superiority of the "Sperry" engine over existing types, it would be necessary to prove two things: firstly, that a slow-speed engine of given power is intrinsically more economical than one of double the speed and equal power; and, secondly, that the toggle link motion is superior to ordinary belt or rope gear. We do not think that it will be easy to establish either of these propositions.

HOUSE-WIRING.

RESUMED DISCUSSION OF THE PAPERS READ BY MESSRS. FRED. BATHURST AND SAM MAVOR BEFORE THE INSTITUTION OF ELECTRICAL ENGINEERS.

Speakers who have revised the abstracts of their remarks have asterisks against their names.

THURSDAY, FEBRUARY 13TH.

*Mr. J. D. F. ANDREWS said he proposed to devote his remarks entirely to concentric wiring. Mr. Mavor was good enough in reading his Paper to attribute the pioneering of that system of wiring to him (Mr. Andrews), and he had pleasure in thanking him for his courteous remarks and acknowledgment. The invention or conception of concentric wiring, even with a bare outer, was not in itself a matter which required much ingenuity, but at the time it was first introduced it was entirely opposed to the then existing ideas and principles, and its introduction was met by great opposition, more especially by the insurance offices, which at that time almost unanimously followed the Phœnix rules. It was a relief, however, to be able to say that that opposition has now begun to die out. Mr. Human, of the Guardian Office, was the first surveyor to recognise the advantages of the system from an insurance point of view. He was sorry to hear Mr. Mavor make proposals regarding inspection by the insurance offices. The tendency of the insurance offices to-day was a proof that they regarded electric lighting as quite a minor source of risk, and that it was unnecessary to employ special skill and issue elaborate rules. The Board of Trade had also begun to show a more generous spirit; in fact, negotiations were progressing satisfactorily with them for his system of concentric mains with a bare, or nearly bare, outer conductor to be laid in the streets of Guildford. The system there to be introduced was the three-wire, consisting of two independent armoured conductors, the armouring of both of which combined formed the middle wire. Great as would be the advantage of concentric wiring for street mains, the greatest advantage would appear in the reduction of the cost of *interior* wiring; this would be quite 20 to 30 per cent. less than with casing or with conduits. The wide introduction of concentric wiring was dependent upon a universal permission to earth the distributing network, a permission that would not alone be good for concentric wiring, but would also be beneficial to all systems of street mains and everything within range of their influence, for the simple reason that the course of the leakage currents would be reduced practically to the distance between the two conductors, instead of, as now, the course being of unknown distance through earth, and consequently having unlimited influence on everything in the course. By earthing the network he did not mean that it should be earthed only at one point; on the contrary, it should be almost continuously earthed, or at each house connection. By earthing one of the street mains he did not advocate that it should be bare; on the contrary, it should be protected against electrolysis and possible chemical action of the soil. The earth connection only should be exposed. The benefits of such a self-testing system would, he was convinced, entirely outweigh the cost of making the conversion. In the concentric system the outer conductor should be absolutely continuous from the dynamo to the lamp, it should be of large section, and entirely envelope the central conductor, also the switches and the fuses. It should be in such close proximity to the inner conductor that it would be impossible for an arc to be established without blowing the fuse. Following those fundamental principles was the only method by which the great advantages of the system could be secured, the reason for which would be obvious when they considered that if the inner conductor was exposed or easily reached at any joint it would be possible for leakage to take place from it without first touching the other conductors. If concentric wiring were to become general, two important changes might be looked forward to in wiring practice: the test to earth would vanish, and the high degree of insulation now required between the conductors would be looked upon as absurd. The insulating material in a concentric wire should be substantial in character and highly durable, but it was only required to insulate to such a degree as not to permit of a greater leakage to take place than might be negligible from a commercial aspect; if it could be possible to obtain reliable insulating material to work at so low a degree, for instance, a wire of 10,000 ohms per mile would only mean a leakage of one hundredth of an ampere with 100 volts. He did not advocate that as the correct degree of insulation to be adopted, but simply gave it as an illustration, and he would point out that it was 60,000 times lower than was at present insisted on in most double wiring.

*Mr. R. J. WALLIS-JONES said it was somewhat interesting to look back upon the progress of electric wiring since, say, 1881. He thought if they looked at the question broadly they would find that the art of wiring had really divided itself into three distinct periods. They might almost say there had been a stone age, a wood age, and an iron age. If the progress shown continued to follow the progress of civilization in other directions then probably the iron age had come to stay. The great difficulty in installation work was the question of moisture. If there was absence of moisture almost any kind of wiring was good enough. He might instance a case in his own experience some ten years ago where he had to wire a new building. In those days, as they well knew, there was no such thing as vulcanised wire in general use. The wires in this installation were simply covered by a pure rubber strip, and he was not at that time aware of the action of various cements and mortars upon the insulation of wire, but he did know this, that the action of plaster of Paris on bare wires was at least harmless, and he buried those wires in channels cut in the walls and fastened them in with plaster of Paris. At the present moment that installation would give as high a test as any he knew of. That was simply an instance proving that where one had no moisture one could do with very light

Digitized by Google

insulation. One of the greatest difficulties of wood casing was the very great uncertainty of the action of damp on the cable inside. He knew one case in particular in which a 19/16 cable was absolutely wasted so that the conductor was dissolved right away and nothing remained but the copper salts. This, on being examined, was found to be caused by a very poor class of insulation around the copper and damp attacking it. The wall on which the cable was placed had become damp by the bursting of a water pipe. In new buildings, however, before the advent of the insulated conduit system, he had seen very successful work carried out with wood casing thoroughly well varnished and put in of a size larger than was absolutely necessary. The casing should be buried and plastered over, and in that way they would find that they could get a fairly good job. No doubt in a wood casing installation there were many mechanical difficulties which were unavoidable. The question of insurance had been touched upon. It seemed that the question of insuring central stations was considered by the fire insurance offices from a very unfair basis at the present time. They made no allowance for the difference in the class of building, but charged one rate whether it was a well-designed or badly-designed station. In one large central station in this country they had taken the matter into their own hands by simply refusing to pay the fire premium and fitting up the station with a proper fire extinguishing plant. In regard to insulated conduit systems he had had practical experience of an installation of about 800 lamps. As they well knew, there were three classes of these conduits—first, the plain bitumen paper tube, secondly, the brass-armoured tube, and then the iron-armoured conduit. The first was somewhat fragile and certainly not very sightly when fixed in position. There was an intermediate type of conduit which consisted of an insulated tube covered with an iron split tubing. He thought that, so far as present knowledge went, if they had to wire a new building with the two-wire system there was no system as good as the insulated conduit, and for this reason, that they could take the building in the carcase and place the tubes readily in position, plaster the whole of the work up, and draw the wires in when they had finished, and they might be quite certain there would be no trouble from bad insulation. As an instance of this he might mention that in this particular installation which he had to do with he tried the other day the experiment of placing a plain steel tube into the conduit for a considerable length. The insulation of that plain steel tube was practically infinity, and therefore a very poorly insulated wire would give very good results indeed. The general way of carrying out work at the present time was to run from the central switchboard a main to a fuse distribution board, and from this fuse distribution board circuits for seven or ten lamps were taken off. Wherever a joint was made a joint box was inserted. He thought the best way of doing work of this kind in the future would be to run the main to the fuse board and from the fuse board run a submain to a joint box, and then run into this joint box the seven or ten-lamp circuits having no joints at all. He had had the pleasure of seeing the concentric wiring as shown by Mr. Mavor. He did not, however, think it very sightly if they were obliged to place the wire on the surface. When Mr. Mavor mentioned sightliness in houses he was probably thinking of Scotch houses, where there were hollow walls and they could run the wires behind. In houses where the system would be placed on the walls it would be a very difficult thing to get a straight line with any flexible conductor such as they had in the concentric system. He had looked into the question of the possibility of drawing wires into insulated conduits system and found, of course, that by blowing soapstone into the conduit they could most easily draw in a considerable length. He should say the average length desirable for circuits was about 60ft. to 70ft., and he found that for the total area of the wires—that was to say, taking the outside of the insulation as compared with the inside area of the conduit—the average was something like 45 per cent. There was one way in which the conduit could be improved—by reducing the diameter. This was an important point in the question of cost, because unless they had a fairly small conduit they had to go so deeply into brickwork that it became exceedingly expensive to instal. From that point of view, of course, the concentric system was a great advantage.

Mr. G. L. ADDENBROOKE said before dealing directly with the question under consideration, he would say a few words on the financial aspect of wiring. It would be found as a sort of rough average that the cost of central stations, with mains, &c., came to somewhere about £100 a kilowatt. A kilowatt capacity of plant was about 25 8 c.p. lamps. They might say an average of 20 lamps, taking 8 c.p. and 16 c.p. together. Roughly, a central station provided for about double the number of lamps installed; therefore, if there was a kilowatt capacity in the station, there would be twice that in the lamps. Consequently, on that basis, they would have about 40 lamps wired for each kilowatt capacity in the station. Now they put these lamps down at an average of £1 apiece—*i.e.*, £40—which showed that whilst they were spending £100 on the central station, £40 were spent in the wiring of houses. The total sum spent on central stations amounted to some millions, and they might take a little less than half that for the cost of wiring This still left a very large sum expended in the past and to be expended in the future in wiring. Therefore, this wiring question was a very important one, and demanded the greatest consideration. For instance, it was greater than any one item in the central station except distribution; in fact, the cost of wiring was infinitely in advance of the cost of dynamos, or the cost of engines, or the cost of boilers, or any other single item. He was extremely pleased to hear what was said on the subject of earthing the middle wire. He must say it seemed to him, if it was not quite hopeless, it was very difficult to make the progress in wiring which they wanted unless that could be done. One of the great obstacles to the extension of the electric light now—and it was an obstacle which was more felt now that the Welsbach was a competitor—was the great cost of wiring houses and the frightful mess which it involved. For this reason numbers of people went without the electric light, although the mains were at their doors, who would gladly pay any little extra cost of the light itself. As to concentric wiring for houses, he had not absolutely made up his mind whether it should be taken simply as it was, or whether they should put in iron pipes. He saw that some wiring contractors, who did a high-class business, were putting in a large number of pipes in their houses. They found that they could put ordinary iron pipes in at something like 4s. a light, and wires were drawn into this; but they themselves had suggested to him that if the middle-wire earthing were attempted, all they would have to do would be to take a little more care in running those pipes, use the iron pipes as the outer, and run the wires inside. It seemed to him that that would make a sound job. It would be Mavor's concentric system, so to speak, so far as the fittings and so on went. It would get rid of the difficulty of burying the conductors, and they could be drawn out at any time.

*Mr. C. N. RUSSELL said Mr. Bathurst's Paper seemed to bring forward as the problem to be solved: "How is it possible to reduce the cost of wiring to one-half what it is at present?" In order to follow the matter he should be glad if Mr. Bathurst would let them know, at what figure he had assumed the present price of wiring. Also, was it proposed that by the use of insulated tubes they could reduce the cost of wiring by 50 per cent., or even 25 per cent? If so, it would be interesting if they could see some figures, of typical installations by way of comparison. The two systems before them, although differing widely, were most excellent each in their way, and if installed properly would do credit to any firm. At the same time it ought to be allowed, that good work could be, and was, done with wood casing, which was very suitable for face work in rooms that were already decorated, and free from damp. He was of opinion that wiring by the use of wood casing could be made to cost less than conduit work. He said could be, because wood casing lent itself to bad work. It could be cut with a pocket-knife and fixed with tin tacks, and as long as the mitres of the capping were fairly made, the job when finished looked all right. On the other hand, if a workman was employed who was paid a fair wage and did his work well, and who was not afraid of taking up the floor boards, for his work to be inspected, he did not hesitate to say, that the cost of wood casing *versus* any conduit system would be about equal, and in a big job would probably be in favour of the latter. Personally he was much in favour of conduit wiring, and would welcome any system that would reduce the cost of good work, but while he allowed the good quality of the systems before them, he failed to see any approach to reduction of cost. He had had considerable experience in conduit wiring, with plain iron tubes, coated with preservative compound, and could assure the members of that Institution that the bogeys raised by Mr. Bathurst in the way of rust, condensation, &c., had caused him (the speaker) no trouble, although the system was extensively used. So far as his experience had been with conduit wiring, he might say that it was well adapted for mills, workshops, and buildings in course of erection, and made a first-rate job, but it could not be done at a price to compete with the so-called cheap wiring at 15s. per lamp. The difference in prime cost between wood casing and plain iron tubes, having the same duty as regards current-carrying capacity, was in favour of wood casing by about 25 per cent., and in the case of insulated tubes, he took it the difference would be greater. As regards prime cost of wiring with plain iron tube conduit, in the case of a mill having 120 16 c.p. lights it worked out at 18s. per lamp, where each lamp had a separate switch, and the work was easy and straightforward. Those figures did not include main switchboard. He had had a few samples of fittings, as used by the London and Lancashire Electric and General Engineering Company, Limited, placed on the table that evening for the inspection of those interested. As far as the merits were concerned of the two systems of wiring before them, he did not think any practical man doubted their excellent qualities for a moment. But he did not see how either of them was going to assist them in reducing the cost of fitting. To do that, it seemed as though they must have a new system entirely, possibly a concentric one, with the outer earthed and with lamps and holders that could be fitted with as little trouble as a gas burner. The present form of Ediswan bayonet-joint lamp holder, so much in use, was in his opinion too complicated, and in too many pieces. The capping of the ordinary incandescent lamp was, he thought, capable of great improvement. A number of lamps of the cheap type, which he tested recently, had such a low resistance between the terminals, across the plaster setting, that in a damp atmosphere considerable leakage would have occurred. Referring again to insulated tubes, he did not quite see what was to be gained in the way of economy, by dividing the insulation and placing part on the tube and part on the wire. Taking the comparative areas of the copper conductor and the inside of the tube, the difference was enormous, and it would seem far cheaper to pay for a first-class vulcanised insulation on the conductor, than trouble to insulate the whole of the interior area of iron tube. There was, no doubt, a lot of bad wiring work being done by so-called electricians, and he thought it would be well if they could have registered wiremen, like the plumbers, who were, he believed, called upon to pass a practical examination.

*Prof. W. E. AYRTON said the points he wished particularly to deal with related to the wire itself. Some time ago he considered these questions: Why have contractors selected particular gauges to employ? What has guided them to certain results? Why, for example, should 1,000 amperes per square inch be selected as the maximum current density? Why should they take 2 per cent. drop between the consumers' terminals and the most distant lamp in the house when all were turned on? Was there any special reason for such numbers, or were they taken purely at haphazard? He thought contractors and electrical engineers had rather mixed up the totally distinct considerations: the question of the gauge which was safe, which did not heat by the passage of the current which it normally took, and the economic gauge to use. If they took the question of the economic gauge they would find that the cross-section was far greater than any cross-section that was liable to heat. The average contractor did not appear to be familiar with the actual cost of the wire.

Digitized by Google

The price of insulated wire was but a very small fraction of the sum charged for putting a certain number of lamps into a house. In order to illustrate what he meant, he would take the case of all the lamps being on the top storey. He had worked out a case of ten 16 c.p. lamps on the top storey of a house with 100ft. of wire to go up and 100ft. to go down, assuming that there were no other lamps in the building; and he would consider what wire they would have to put in such a case if they were going to have 1 per cent. drop and if they were going to have 2 per cent. drop, how much it would each cost in such a case, and what was the difference. If they had the 2 per cent. drop, the actual cost of the wire, class S of the Silvertown Company's list, for those ten 16 c.p. lamps was 12s. If they took 1 per cent. drop, then the cost of this same 600-megohm wire was 17s. The difference in cost, therefore, was 5s. The labour was practically the same. Now was it worth spending that extra 5s.? In this case, as all the lamps were supposed to be at the top of the house, it would be possible to use lamps intended for a lower pressure than was maintained between the consumer's terminals. Suppose, for example, the declared pressure was 100 volts, they might use 98-volt lamps with the 2 per cent. drop or 99-volt lamps with the 1 per cent. drop. The difference would be about 1 per cent. in the current. Both gave 16 c.p., and they paid roughly for 1 per cent. more current to produce the same amount of light in the case of the 2 per cent. drop, than with the 1 per cent. drop. Supposing these lamps were turned on for 1,000 hours during the year, and the Board of Trade unit cost 6d., the total came to £16, or 320s., and 1 per cent. on that was little more than 3s. With a 2 per cent. drop they would in two years have more than paid to the supply company the difference in cost between 2 per cent. drop wiring and 1 per cent. drop wiring, and ever afterwards they would be gainers, supposing they had put up a thicker wire. Now take the real case—that was, where there were lamps all over the house and where it was quite impracticable to have lamps of different pressures on different floors. Taking an ordinary installation with a pressure of 100 volts, only 100-volt lamps would be bought, and on this top floor they would have 98 or 99 volts instead of 100. The difference of 1 per cent. at near the normal working pressure meant about 7 per cent. in the light. They had to pay extra for the same amount of light, or they got 7 per cent. less light than they had paid for. Then it came to this: If they put in the thicker wire for those 10 lamps at the top of the building they would pay 5s. more to start with, but they would save 7 per cent. on 320s., 21s. a year all the time they were keeping those lamps turned on for 1,000 hours during the year, and paying 6d. per Board of Trade unit. It was clear, then—and the same result came out whatever the number of lamps, and however distributed—that a 2 per cent. drop was an enormous extravagance—was an extremely bad investment for anybody who could scrape together enough money to have the thicker wire. Another interesting question arose: What was the best drop to have? He spent a good deal of time four years ago going into that problem mathematically. He need only give them the answer. The best gauge to use, the best cross-section, the most economical—assuming that they were going to pay for the installation out of their own pockets, and going to pay the supply company for electric energy afterwards—the most economical was copper as thick as they could put it in, so as not to materially increase the cost of labour. Therefore, for two mains going to any part of the building, if they had any choice between the two, if there was not sufficient difference in the thickness to make the cost of labour in wiring materially different, then the thickest was the best, provided they were dealing with glow lamps such as they now knew them, and with prices of wire and current as they now were. This result led to another very interesting one, and that was, it enabled them to dispense with a great number of fuses. The old idea was—and they found it probably still in some specifications—to put in a fuse wherever the gauge of wire changed. Was that necessary? If they followed out the first rule it was absolutely unnecessary. He held in his hand a flexible wire which took the current for a 16 c.p. lamp at about 450 amperes per square inch. This flexible wire was joined to a main wire. Now did they want a fuse. What current would this insulated wire stand? Nobody seemed to know. This wire had actually had 30 amperes passing through it for half an hour. The other which he held in his hands had had 35 amperes passing. If they had these flexible wires attached to a pair of mains which had a 10 or 15-ampere fuse, those wires were absolutely safe. Therefore, if they had a pair of mains supplying 10 or 15 separate lamps through pairs of flexibles the room would be absolutely safe if they had outside, where the mains entered the room, a fuse which would go at, say, 10 or 15 amperes without any separate fuses being used for each ceiling rose or lamp. It seemed to him extremely advisable that an installation should be so divided up that they could practically use everywhere the same fuse, or where that was impossible the fuses should be made absolutely uninterchangeable, so that neither a fuse of too large, or of too small a section could be inserted. Now about insulation: so far he had only been dealing with the cross-section of the copper. He was an advocate of high-insulated wire. He knew it would be said that the main leakage was at fuses, switches and lampholders, and it was no use asking for wire which would have 2,000 megohms after 24 hours' immersion in water at 60°F. That was not a right argument, because they could clean the switches, whereas they could not get inside the wires. Another thing: one of the reasons why so much of the leakage occurred at the switches and fuses was because so many of them were so extremely badly designed. They would find two screws attached to the two main wires a fair distance apart, but for the fact that between them was another screw which held the switch of the fuse to the board at the back and so the surface insulation was reduced most unnecessarily. It was quite easy to arrange switches, or fuses, or lamp holders, without having them perceptibly bigger than now, and yet increase the insulation. A list was given in Mr. Bathurst's Paper of the standards employed in different countries; but a high standard which was now employed by several companies in this country was left out—namely, 80 megohms per lamp. Could they get that insulation of 80 megohms in a comparatively new building? His experience was that they could if they used good material and attended to two important points: one was always to have the tape which was outside the insulated wire stripped off at the end so that it could never come into contact with a piece of metal which was part of the live system, and another thing was to take care that the screws which passed into the porcelain, and which were used to attach wires to it, did not go right through and touch wood or something else at the back. If they looked after those two things and got good material, his experience was that they could get that insulation even in buildings which had only been erected for two or three months. There was just one other point he would like to mention in passing, and that was about the iron tubes. He had some little doubt some time ago whether, in the case of two wires, the going and return conductor, drawn into an iron tube, the wires being a good deal smaller than would fill up the tube, there was not, with a 100-period alternating current, some self-induction effect that would interfere and cause a slight extra drop. Experiments, however, showed that that was not the case with the ordinary wrought-iron tube. With reference to the remarks of the last speaker as to an examination for wiremen, it would interest him to know that recently that had been started by the City and Guilds of London Institute—not only a written, but a practical examination to test their knowledge of jointing and things of that kind.

*Prof. S. P. THOMPSON said there was one paragraph in Mr. Bathurst's Paper which seemed to him very important. It was that if they had two conductors in a pipe, and one of those conductors broke down and made contact with the uninsulated pipe, a new condition of things was set up; and it was that new condition of things that he wished to emphasise. The wire which had made contact with the pipe had now virtually got an increased carrying capacity, owing to the fact that there was a pipe parallel with it, and the other conductor, therefore, would be more liable to over-heating. Further than that, the insulation having gone on one side and practically made an earth—it might be only a local earth for the time being—there was a greater strain thrown on the insulation of the other wire. If they got anything like 200 volts into their houses it was of the greatest importance that if they had a conduit system at all there should be some kind of mechanical insulation—it need not be a high insulation—inside the pipe itself. There was a great deal to be said for a double insulation. In other conditions of electrical engineering they absolutely must have double insulation, high electrical insulation and high mechanico-electrical insulation. There was that advantage in lining the pipe with an insulating material—it might be with ozokerited paper, or something of that sort—it did prevent mechanical contact between the wire that had broken down for the time being and the iron pipe. A double insulation, he contended, was a distinct advantage. He made an experiment in wiring some years ago. He put himself in the position spoken of by Prof. Ayrton. He did not want to save 6d., but he wanted something that was perfectly safe, and would not have an inch of wood casing anywhere. He employed stranded wires highly insulated in most cases, but in one part of the house where there was not the slightest likelihood of damp having any effect he employed a relatively lower insulation. But in every case, whether the insulation was of a really high character or only of a moderate character, the wires were enclosed, each separately, in a lead coating, which was drawn on, and then the two lead-coated wires were put together side by side with a little filling in between, and braided round together, so as to form a braided twin. He objected altogether to fuses being put up where you could not get at them—in ceiling roses and other places; he thought they ought in such cases to be objected to by the Board of Trade. He would like to have every fuse placed so that it could be replaced without difficulty when the lights were on. He had had no experience of concentric wires; he saw there were obvious advantages, but like the wiring in his own house, and like many other examples where wiring was put in that did not admit of replacement, there was the obvious disadvantage that they could not materially add to the number of lamps originally designed for. He had made a few experiments on the likelihood of different kinds of conduits breaking down, but they were not in such a state that he could quote them yet; but it seemed to him to be a great point that there was greater safety where a pipe, if of metal, was lined with a fairly strong and fairly good interior insulating material.

*Mr. MAVOR, replying to the discussion so far as it had gone, said Mr. Geipel was the first speaker, and he opened his remarks by criticising the high standards of insulation set up by the fire companies. He (the speaker) thought the fire companies were wise in setting a very high standard indeed, because of the susceptibility of double wiring and wood casing to the attacks of moisture, and to the other many ways in which faults were liable to occur. It was only by setting a very high—in fact, what seemed almost an impossibly high—standard of insulation that good work of this bad kind could be secured; any withdrawal from the high standard would lead contractors to become more careless, and to take any departure from that standard as a licence to do less careful work than they had been doing. Mr. Geipel favoured wood casing, because the work could be done by joiners. In his opinion the whole of the work had too often been done by joiners. We have all seen joiners' joints Mr. Geipel objected to concentric wiring, because it required tradesmen to erect it. He (Mr. Mavor) thought that was one of its strongest points. Mr. Geipel said cost alone was the vulnerable point of double wiring. He (Mr. Mavor) said it was not; the whole system bristled with vulnerable points. Every joint was a vulnerable point, every one of the double-contact lampholders was a vulnerable point; in fact, the whole thing was vulnerable unless they made it systematically damp proof from end to end. With regard to the comparative cost of double wiring and concentric wiring, it was a very difficult question. If he asked one contractor what was the cost of double wiring he would give one figure, whilst another would give 50 per cent. less. When they compared the cost of concentric wiring with the cost of double wiring it should be with a first-rate double-wired job, and where they did that concentric wiring was invariably cheaper. He had never seen a building yet which he

Digitized by Google

could not wire more cheaply with concentric than with double wiring. Mr. McLean, of Oxford, asked how many concentric joints there were beneath the floors and behind plastered walls. Well, there were many thousands of them, and they had never had cause to get at any one of them yet. Mr. Langdon advocated the inspection of wiring by the supply companies. It seemed to him, however, that that was not the business of the supply companies at all, and they should have as little to do with it as possible. Mr. Swinton was in error in supposing that two staffs of wiremen were necessary if a contractor wished to adopt the two methods. That was quite a mistake, as several contractors who had adopted concentric wiring had found out; there was really nothing about it that any intelligent workman could not pick up in half an hour. Not only were two staffs of men not necessary, but the staff of men required to do any particular job was very much reduced. Mr. Swinton and another speaker had referred to the current-carrying capacity of the wires in relation to the size of fuses. He thought the current-carrying capacity of the wire had very little to do with the fuse at all. There was very little danger of the wire being heated throughout its length by the current. The danger was from the heat being concentrated at any one point. He thought, therefore, a fuse should not be proportional to the size of the cables, but to the current they had to carry, and should have as small a margin over that current as safely might be. This was an extremely important point, and since the rules of the Institution were under revision, one rule should be added, if it had not already been considered, and that was to limit the amount of current which might be allowed in any one conductor within a building, and he submitted that something like 50 or 60 amperes should be the maximum. They might increase the number of sub-mains, but the whole point was to keep down the main fuses to as small a size as possible. With regard to earthing the distributing system, his opinion was that the feeding points were the proper points to earth—insulated feeders up to the feeding point, and at every feeding point a definite earth, and of such a character that it could be removed for testing purposes, if necessary. Mr. Wallis-Jones spoke of the unsightliness of concentric wiring, and thought it not suited to internal house work. Mr. Wallis-Jones had not seen it. He (Mr. Mavor) would be very happy to show him examples of such work which would entirely remove his impression. Mr. Swinton was under entirely the same impression, and it had been removed. Mr. Addenbrooke said for ship lighting, concentric wiring was so obviously the right thing that he was surprised it was not more generally adopted. The reason was this: Wood casing was nearly always included in the ship builder's contract; when an owner asked for tenders for wiring the contractor tendered for wiring only, without the wood casing. Any tender for concentric wiring was obviously seriously handicapped. With regard to Prof. Ayrton's remarks, he wondered whether Prof. Ayrton was interested in some cable company; his views with regard to the size of cables would almost indicate that he was. Prof. Ayrton and many other speakers seemed bent on drawing wires in and out of tubes. Why on earth should they? If they put up a job to last, why should they want to keep pulling it out? He could not understand it. He never had occasion to do so. Why they should go to all the trouble of blowing in soapstone and so on he did not know. He had to thank them for the kind reception of his Paper, but he was rather disappointed that so much time had elapsed since the Paper was read, for many of the members who had spoken seemed to have forgotten that any Papers had been read, or to have forgotten what they were about.

The discussion was then adjourned until February 27th.

PARIS NOTES.

(FROM OUR OWN CORRESPONDENT.)

PARIS, *Feb. 18, 1896.*

A New Parisian Electric Light Network.—Since the beginning of the year Paris has been enriched by a new electric light "sector" on the left bank of the Seine, which portion of the metropolis had not previously possessed any electrical system of distribution whatever. Many attempts were made to get to work, and in 1894 a concern, to which the concession had been transferred, hired a small continuous-current station, which had never been used, near the Place du Panthéon, and from this supplied a few customers whilst getting out the plans for a large station. This station is on the banks of the river at Issy, outside Paris, and is now partly constructed. Steam is supplied by seven multitubular boilers, each capable of giving 3,000 kilogrammes of steam per hour at 170lb. pressure; later on there are to be 20 such boilers. In the engine room there are horizontal compound 700 H.P. Creusot engines running at 125 revolutions. Each of these has between its two cylinders a Creusot-Zipernowski 400 kilowatt 3,000-volt alternator having a frequency of 42. The fine distributing board is situated on a large balcony 19 metres long. Felten and Guilleaume armoured, lead-covered, concentric jute and paper insulated cables are used, laid direct in the ground in a bed of sand. Two feeders of 200 sq. mm. cross-section start from the station down the Rue Lecombe and then divide, one going along the Boulevard des Invalides, and the other along the Boulevard du Montparnasse. They unite at the Boulevard St. Michel. This ring arrangement enables the supply to be kept up by one branch when work is being carried out on the other. The primary circuit feeds various transformer sub-stations, the secondaries of which consist of bare copper conductors run on insulators in cement conduits under the pavements.

X-rays at the Société Internationale des Electriciens.—The monthly meeting of this Society took place on the 5th inst. under the *ægis* of M. Violle, Vice-President. M. Perrin gave an interesting historical *résumé* on the subject of X-rays.

The New Heilmann Electric Locomotives.—The first Heilmann 800 H.P. electric "loco.," it will be remembered, hauled a light train at the rate of 108 kilometres an hour—say 67 miles an hour. In consequence of the success of the "locos." the Compagnie des Chemins de Fer de l'Ouest determined to test two more powerful Heilmann "locos." hauling heavy trains at high speed. These "locos." are now in course of construction at the Cail shops, and will shortly get to work. It is intended that they should haul trains of 290 tons at the rate of 62 miles an hour. The horse-power aggregates 1,900 H.P. The apparatus will be mounted on two 4-wheel bogies. The front portion of the cover of this moving central station is tapered to reduce the resistance of the wind. A single Willans engine drives direct on to two generators, one on either side. The electric motors are gearless, driving the axles through elastic couplings.

CORRESPONDENCE.

ELECTRIC TRACTION AND TELEPHONIC DISTRIBUTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I wish to make the following remarks with regard to the article in your issue of January 10th, "Electric Tramways and Telephonic Disturbances," by Mr. C. S. du Riche Preller:—

Most of the conclusions made in this article are incorrect and misleading. They tend to increase the amount of misinformation in regard to this important subject, not so much in well-informed electrical circles, as among the general technical public, who naturally assume that such statements made in a journal of the standing of *The Electrician* come from a perfectly reliable source. I therefore think it advisable to place before your readers the corrected facts.

First.—The method of suspending the contact wire on electric railways has nothing whatever to do with telephonic disturbances. It is perfectly immaterial whether the suspension wire clamps are soldered on to the wire, or whether they are mechanical clips. It is also unimportant in regard to the telephonic disturbances whether, on the suspension points, the wire is smooth or rough, whether these clamping pieces are two years old, as at Zurich, or only a few months in service, as at Basle. All this has not the slighest influence upon the production of the well-known *continuous* sounds produced in telephones by electric railway circuits, which are in close proximity to earthed telephone lines. Were the sounds actually produced by the interruptions of the current at the points of suspension, then they would not be continuous, but would be heard at intervals of from 8sec. to 15sec., according to the distance of the clamps. Everyone—not only an electrician, but every layman—who has once heard this peculiar continuous hum will at once recognise the incorrectness of the statement that the sparking at bad suspension points "is the first cause of telephonic disturbances."

Second.—Next comes the generalisation of some observations on certain Continental electric railway lines, which are operated with *trolley contacts* and others operated with *sliding contacts*. According to Mr. Preller, lines with trolley contacts cause serious troubles in telephone circuits, whilst those with sliding contacts do not produce such disturbances. This statement has no foundation from a theoretical point of view (the trolley has a larger surface in contact with the wire than the sliding rod), and is in contradiction

Digitized by Google

with facts established long ago. The shape of the contact cannot and actually does not alter the conditions causing the telephone troubles, and I only need to refer to the experiments carried out at Leeds in 1893 by Mr. James Swinburne, a record of which is given in his evidence before the Joint Committee of Lords and Commons on Electric Powers (*The Electrician*, June 30, 1893, p. 236), and also to the series of experiments carried out at Zurich in 1895 with long sliding shoes in comparison with trolleys, to which Mr. Preller refers himself in his article.

Third.—The disturbances in telephone circuits are independent of the design of the motor, if this machine is an ordinary continuous-current motor for railway work. It was clear to every member of the electrical profession, up to the present moment, that the noise as produced by the spur or any other gearing between the motors and the car axles had nothing in common with the electrical phenomena of induction between railway add telephone circuits. It was reserved for Mr. Preller to consider for the first time even such an absurd possibility, and he states that chain gearing, when running noiselessly, has less effect on the telephone induction than the standard railway spur gearing! Well, I can assure the gentleman from my own experience that neither chain gearing, may it even howl as bad as on some older cars in Budapest, nor any other gearing can produce disturbances through electric induction in telephones, if other conditions for such influence are lacking.

Fourth.—This is not the proper place, nor is it my intention, to enter into the discussion of the real causes of telephone disturbances by electric railway circuits. This matter has already been thoroughly and carefully investigated from a scientific and practical standpoint by many competent electricians. I only need to refer to the proceedings before the Joint Committee of Parliament in 1893, already referred to above; to the long discussion of the Elektrotechnischer Verein of Berlin, in 1895 (*Elektrotechnische Zeitschrift*, 1895, pp. 417 and 443); to the articles of Mr. Vuilleumier, who investigated the matter as early as 1892 (*L'Industrie Electrique*, 1892) at Clermont-Ferrant from the standpoint of a practical railway manager; and of Messrs. Meyer and Muetzel (*Elektrotechnische Zeitschrift*, 1894), who made exact theoretical investigations and experiments on the electric tramways of Breslau. I only wish, in the name of the Maschinenfabrik Oerlikon, the firm which has constructed the lines of Zurich and Marseilles, to protest against Mr. Preller's inexact and incorrect conclusions, which are apparently based upon the accidental observations of a pleasure traveller on the Continent. Mr. Preller never carried out "tests" at Zurich or Marseilles in order to ascertain the causes of telephonic disturbances, unless he calls a speech in a public telephone station a "test." The real causes of the disturbances were, after careful examinations, found to be the following:—At Marseilles it was entirely insufficient insulation of the old telephone lines, which had earth returns only. At Zurich the disturbances were mostly due to the extreme softness of the soil; on all four lines the rails are placed in unpaved streets of the suburbs and the earth currents are thus allowed to spread out over a large area. Contrasting with these conditions is the situation at Basle. The whole line is only 1¾ miles long from one terminal to the other, and on its longest portion the rails are embedded in wood pavement, which acts as a good insulator against the earth currents.

I leave it to the reader to form his opinion about the value of Mr. Preller's observations.—Yours, &c., EMILE KOLBEN.

Oerlikon b. Zürich, February 12, 1896.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It will be patent to every impartial reader of the above letter that, whatever may be its intended effect, it is entirely vitiated by its animus.

In the Paper to which that letter refers, I advisedly abstained from mentioning names; and more especially of the electrical defects of the Zurich lines, I spoke with the greatest reticence. Herr Kolben is electrician to the Oerlikon Company, who, as he states, supplied the electrical equipment of those lines. His ebullition affords signal proof that the cap fits remarkably well. Moreover, his remarks are directed not only against myself, but, notably against Siemens and Halske's system, which, owing to its undoubted intrinsic superiority, has proved a great success at Basle, and has thus taken root in Switzerland. That fact is, no doubt, very unpalatable to the Oerlikon Company.

As regards the facts I brought forward in my Paper, Herr Kolben has not controverted them. As regards the conclusions I deduced from them, there may, of course, be divergence of opinion; but my conclusions are, at any rate, fully endorsed by some of the most distinguished French and Swiss electricians (not manufacturers), who, after publication of that Paper, wrote to me to that effect, and whose names I enclose. Herr Kolben is not an independent witness in this matter.

Moreover, my investigations were not only absolutely disinterested and impartial, but had a strictly professional and definite object, viz., in view of a specific case in Italy where telephonic interference was apprehended, I had to determine which of the various contact systems would be the most suitable; and in this inquiry I was guided simply by the maxim, "Examine everything, and choose what is best."

As regards the personalities in which Herr Kolben indulges, I can well afford to ignore them.—Yours, &c.

C. S. DU RICHE PRELLER.

P.S.—I may perhaps say that the tests of which I spoke in my Paper, were not measurements made on the line, or I would have given the figures. Such measurements had no direct bearing upon the immediate object of my investigations. The tests consisted in a large number of comparative observations of the effect of the working of the electric tramways at a variety of telephone stations, under varying atmospheric conditions, and at gradually increasing distances from the line. These observations extended, at Zurich alone, over a period of two months, and the results are very instructive.

I need hardly point out that the rattle of the gearing on the Zurich lines has, *per se*, nothing to do with telephonic disturbances, but that the uneven working of the motors produced by worn out, or otherwise imperfect, and therefore noisy gearing, gives rise to uneven currents in the line and hence aggravates telephonic disturbances.—D. R. P.

COLONIAL ELECTRICAL ENGINEERING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of the 8th inst. I notice a letter from Mr. Geo. F. Pardoe on "Colonial Electrical Engineering," which afforded me no little amusement by its graphic description of the Moss Vale plant. Having had charge of two central stations in Australia, and having been engaged on the construction of others there recently, I am in a position to bring the information a little more up to date, and for the credit of electrical engineers now in the Colonies I would say that during the last two years or so much creditable work has been performed, and improvements effected in existing installations.

The wreck so faithfully described was superseded some two years ago by a 50 H.P. direct-coupled combination of Willans engine and Kingdon inductor alternator, the low-tension system being abandoned for high-tension alternating-current with transformers. This work was carried out by the Sydney branch of the Woodhouse and Rawson Company. The railway station and refreshment rooms are now lighted electrically.

The Newcastle (N.S.W.) central station was not long ago overhauled by a well-known electrical engineer now in Sydney, and has since given eminently better results. The only central station, I think, where underground mains are employed is that at Rockhampton. Low-tension distribution is used for the central area, high-tension alternating for suburban districts. At Brisbane, a small station, owned and worked by a local firm of electrical engineers, has been running successfully for a number of years. In the central

Digitized by Google

portion of the city of Sydney an electric lighting company is earning large profits, and has been in operation about three years. The municipal central station at Redfern (Sydney) has now been running successfully for nearly four years.

The Ballarat (Victoria) Electric Lighting Company opened their works about twelve months ago, the plant being almost over-loaded before starting. Crompton-Pochin arc lamps of 3,000 c.p. each are used for lighting the broad streets of this beautiful city. At Nhill (Victoria) a small continuous-current central station has been running with success for three years. Several other central stations in New South Wales are of the kind which bring discredit on electric lighting, too many examples of which are still in existence.

I fail to see any justification for the use of countershafting at Melbourne central station, although the plant is an admirable one in its way. There seems to be an abnormal tendency in the Colonies to follow American practice, probably on grounds of economy. Rather a doubtful policy, judging from some results.—Yours, &c., HENRY J. SPENCER.

Martin's-chambers, 28, Martin's-lane,
Cannon-street, E.C., February 12, 1896.

X-RAYS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As it has been announced that Prof. Borgman has discovered that the Röntgen rays increase the sparking distance in a spark gap, an account of the results of a few experiments I have been making on this subject, under the guidance of Prof. Ewing, may be of interest to some of your readers.

For a spark gap I used two brass balls, about 8mm. in diameter, whose distance apart could be varied and measured. To screen ultra-violet light and electrostatic effects this apparatus was put into a metal box, with one side removed for purposes of observation, and with a hole in the opposite side covered with aluminium foil 0·04mm. thick. A Crookes tube was placed close outside this aluminium "window."

The spark gap connected with an induction coil was then adjusted to such a width that a spark occasionally passed; on exciting the tube the sparking considerably increased. Owing to variations of the potential it was not possible in this way to cause regular sparking when there had been no sparking before the tube was excited, but by counting the number of sparks per minute the effect of the Röntgen rays was very evident.

For example, in one experiment I used a spark gap 1·5mm. wide, and placed the tube 4cm. or 5cm. from it. I then counted the number of sparks per minute when the tube was alternately disconnected and excited; the mean number of sparks per minute was five when the Crookes tube was not in action, and 25·8 when it was in action, for ten minutes' observation. A piece of zinc 1mm. thick placed between the tube and the window completely stopped this effect. The tube being excited, the average number of sparks per minute was 1·5 when the zinc was before the window, and 22·0 when it was taken away for ten minutes' observation. Ebonite 1mm. thick made but little difference. Platinum 0·02mm. and iron 0·17mm. thick partially stopped the effect.

The tube I used for these experiments did not give good photographic results.

Another tube, which showed green phosphorescence very well, had no effect on the sparking when excited by an induction coil only; but when excited with a Tesla coil its effect was very marked.—Yours, &c., CHARLES J. P. CAVE.

Engineering Laboratory, Cambridge,
February 19, 1896.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In order to ascertain whether Röntgen rays will pass unaffected through a coal-gas flame, or whether they would cast a shadow of the flame upon a suitably arranged sensitive plate, the following experiment was tried: A pear-shaped Lenard tube capable of giving off the Röntgen radiation was suspended so that the rays passed out of the tube in a horizontal direction. A sensitive plate, enclosed within a light-tight wooden box, was then placed about seven inches from the tube and arranged to receive the radiation from it, while between the tube and the plate, at about five inches from the former, a small steady gas jet was lighted.

After twenty minutes exposure the plate was developed and the negative showed a clear image of the gas burner, but no indication of the flame whatever. The rays, therefore, had passed through the sheet of flame apparently unaffected and no shadow was produced; this is all the more curious when it is remembered how opaque carbon is to the rays, and that a quantity of it in a state of incandescence was present in the flame, to say nothing of the excessive molecular agitation taking place in its neighbourhood.

I may point out also that during some experiments made to compare the opacities for Röntgen rays of certain substances, camphor was found to be strikingly transparent; more so, considerably than amber, a particular specimen of which showed a marked transparency as compared with glass, topaz, mica, quartz (which is very opaque) and some others.

So far it seems difficult to classify substances with regard to electrical conductivity according to their behaviour towards the new rays. We cannot say, in fact, from the data that a particular substance is transparent to the rays, whether it will conduct electricity or not.

The metals, good conductors of electricity, are, except when very thin, generally opaque to Röntgen rays; but then so is glass and many other *non conductors* of electricity, while camphor, again, which is a non-conductor, is exceedingly transparent to the rays.

Up to the present, however, the behaviour of organic tissues appears more uniform, all being fairly transparent; feathers, skin, flesh and so forth particularly so. In order to get sharp "rontographs" I have found it an advantage, therefore, to use a leather layer to protect the sensitive plate from light during its exposure to the new radiation.—Yours, &c.,

Castle House, Shooters' Hill, Kent, C. E. S. PHILLIPS.
February 18, 1896.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: At the suggestion of Lord Kelvin, I placed my sensitive plate in a tight zinc box, with an aluminium window in the lid. Objects such as small brass wheels were placed either inside the box, or outside on the aluminium window. The box was then earthed carefully, and placed between the poles of my large induction machine. The poles were 2ft. apart, to prevent sparking, as in all my experiments I have used the silent brush discharge. Good photographs were got in about half an hour. The object of placing the photographic plate in a metal box earthed was to prevent the possibility of discharge on to the plate.—Yours, &c., BLYTHSWOOD.

Blythswood, Renfrew, N.B., February 17, 1896.

American Government Engineering Laboratories.—The *Electrical World* of New York states that a Bill has been introduced into the United States Congress for the establishment, in connection with the State colleges and universities endowed with the proceeds of national land grants, of experiment stations for the mechanic arts, which shall, in their relation to engineering education and scientific investigation, be analagous to the several existing State agricultural experiment stations with respect to agricultural science. To accomplish this it is only necessary to extend the provision of the Hatch Act of 1887 to embrace the mechanic arts. It is proposed that the internal organisation of such engineering experiment stations follow closely that of the official stations now to be found in every large German town in connection with its university and technical school, and, especially, of the mechanical testing station at Charlottenburg. It is advocated that what has been done by private munificence in several of these lines of engineering in the laboratories of our technical schools, should be extended and made possible by federal aid in every land grant college and university.

LEGAL INTELLIGENCE.

Edison and Swan United Electric Light Company (Limited) v. Williamson and Joseph.

This action came before Mr. Justice Romer, in the Chancery Division, on Friday and Saturday last, and was for an injunction restraining the defendants from selling or otherwise disposing of holders or sockets for incandescent electric lamps made in accordance with the patents comprised in a licence granted in July, 1890, by the plaintiffs to Appleton, Burbey and Williamson for less prices or under more favourable terms and conditions than the retail prices, and terms and conditions from time to time charged by plaintiffs for similar goods, and from making or allowing any discount, commission, rebate, return gift or allowance to customers greater than that allowed by the plaintiffs, who also claimed damages.

The plaintiffs granted to the licensees full but not exclusive licence to use, sell, and dispose of holders or sockets of incandescent electric lamps made by the licensees, the plaintiffs receiving a royalty of 10 per cent. on the Company's retail prices on all holders or sockets manufactured by the licensees or otherwise disposed of, with a minimum royalty of £50 per half-year, the licensees at the same time agreeing not to make or allow any discount, commission, rebate, return, gift or allowance to customers greater than the discount from time to time allowed by the plaintiffs off the retail prices. The plaintiffs alleged that the defendants, who were the successors in business of Appleton, Burby and Williamson, and assignees of the licence, had sold holders or sockets for less prices and under more favourable terms and conditions than those mentioned in the licence, and had allowed to their customers discount exceeding the maximum discount authorised by the plaintiffs. In particular the plaintiffs alleged that the defendants on May 17, 1895, sold to a Mr. John Clark a parcel of fifty holders at the lowest retail price quoted by the plaintiffs less the greatest authorised discount, and in addition thereto and in breach of the covenant made a gift to Mr. Clark of eight holders or sockets equivalent to a further cash discount of 16 per cent.

The defendants denied that they sold any holders or sockets the subject of the licence under more favourable terms than those stipulated in the arrangement with the plaintiffs, and also pleaded that the holders or sockets sold by them were not manufactured by the plaintiffs, and submitted that the fixing of the prices by the plaintiffs, after hearing the defendants or licensees, was a condition precedent to any complaint by the plaintiffs, and that by reason of the non-performance of such condition precedent the plaintiffs' action must fail. The defendants did not admit that any gift or present was made to Clark, and that if any such were made to him it was by a Mr. Congdon for his own benefit, and made by him without the authority and contrary to the express instructions of the defendants.

Mr. Fletcher Moulton, Q.C., and Mr. Eve, Q.C., appeared for the plaintiffs, and Mr. Gatey for the defendants.

Mr. MOULTON observed, in opening the case, that it was a matter in which perfect good faith must be observed among the licensees, else one selling at a lower price would be likely to get the whole of the trade. It was a duty cast on the plaintiffs to proceed against anyone for breaches of the restriction contained in the licences. They asked for an injunction, and with regard to damages, he submitted that they were entitled to an inquiry. This was a case in which they were unaware of the full extent of the breaches.

His LORDSHIP asked what the defendants' contention was.

Mr. MOULTON replied that they were going to say that these were not holders or sockets of a similar description to those manufactured by the plaintiffs.

Mr. GATEY said the defendants intended to raise that point. They were admitted to be articles not manufactured by the Company; they were manufactured by the defendants.

Mr. Justice ROMER: But the question is whether they are of a similar description.

After hearing the evidence,

Mr. Justice ROMER said he accepted the testimony of the plaintiffs' witnesses.

Mr. GATEY signified the willingness of the defendants to give an undertaking to abstain from a repetition of the acts complained of.

Mr. Justice ROMER: Mr. Eve, would not nominal damages suit your clients, say 40s.? It is better than a costly inquiry.

Mr. EVE: I think so, my lord.

Mr. Justice ROMER said there was a discrepancy of evidence; but as he had said, he accepted the testimony of the plaintiffs, and he must say that he thought Mr. Joseph, Mr. Congdon and Mr. Williamson were mistaken in their testimony. This was a case where admittedly there had been breaches of the licence previous to March, 1895. Since that time a further breach had been proved. He was not satisfied that that was the only one. Substantially, he thought what happened was this. He thought about March, 1895, or perhaps a trifle earlier, the defendants, or, at any rate, Mr. Joseph did, became alarmed about the granting of further rights, and were a little alarmed at the course they had been pursuing up to that time with regard to breaking the licence. He thought they communicated to their employés the fact that no greater discount should be allowed than 33⅓ per cent. He was not satisfied that there was only one instance of breach. Nobody could follow the transaction completely. He should say no more about it, seeing that the defendants had offered an undertaking which the plaintiffs accepted. The defendants tried to escape from the action by asserting that the holders which they had been selling were not of a similar description to those manufactured by the plaintiffs, and included in their price list. There was a difference between them, but it was not a material difference for the purposes of this case. The holder was similar to the holder sold by the Company and mentioned in their price list. He was supported in that view by the fact that defendants and their employés always treated the holders they sold as similar to the plaintiffs. He need add no more after what had passed except to say that he awarded the plaintiffs 40s. nominal damages instead of an inquiry, the paintiffs being willing to adopt that settlement. The defendants would, of course, pay the costs of the action.

Judgment for plaintiffs accordingly.

South Staffordshire Tramways Company v. Ebbsmith and Wain.

The hearing of this action was continued before the Lord Chief Justice. As stated in our last issue, it was brought to recover damages from the defendants for alleged fraudulent conspiracy in connection with certain transactions between the parties. A mass of evidence of the most conflicting nature was given, after which Mr. Ebbsmith addressed the Court on his own behalf. After hearing counsel, on Tuesday, the Lord Chief Justice summed up at considerable length, and the jury eventually found that, in the matter of the land, the defendants Ebbsmith and Wain had acted in concert, and had defrauded the Company to the extent of £7,313; that there was conspiracy between the defendants as regarded the patents, and on this head found damages to the amount of £1,650, and profits improperly made £500, in all £2,150; that, in respect to the packed meetings, the defendants were both parties to the misappropriation of the Company's funds to the amount of £362. The jury also found that the plaintiffs were entitled to interest on these amounts at 3½ per cent. Judgment was entered on Wednesday morning against the defendant Ebbsmith in respect of the land for £9,478, and against Wain for that sum less £800; against both defendants in respect of the patents for £2,568, and in respect of money misappropriated for payments to shareholders for £412. It was further decided that the defendant Ebbsmith was entitled to the reconveyance of the land, at his own expense, on payment of the debt and costs.

Hopkinson and Co. (Limited) and Dewrance and Co. v. Baldwin.

An action came before Mr. Justice North on Friday last, brought by Messrs. J. Hopkinson and Co. (Limited), of Britannia Works, Huddersfield, and of Queen Victoria-street, London, jointly with Messrs. J. Dewrance and Co., of Great Dover-street, London, engineers, to restrain the defendant, a brass founder, at Keighley, from infringing the joint patent rights of the plaintiffs, which they have united to maintain for the manufacture of improved water-gauges. The evidence showed the patent rights had become well established, and were in use by the Admiralty and other large steam users; that the defendant had recently commenced to make gauges having within them the principles of the patents of the plaintiffs, and that he was advertising them and supplying them to the trade. The defendant was perpetually restrained from continuing to infringe; was ordered to withdraw all infringements from his customers and his advertisements; to hand over his catalogues and drawings to the plaintiffs' solicitors for destruction; to deliver to the plaintiffs all infringing gauges; and to pay the costs of the action.

Gaskell and Grocott v. Gosling.

Judgment in this action was to have been given on Friday last, and was further postponed to Monday, and then again adjourned.

TRADE NOTES AND NOTICES.

[Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.]

SPECIAL NOTICE.—The 1896 (fourteenth annual) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is NOW READY. The published price of the Directory and Handbook is 7s. 6d., post free 8s. 3d., abroad 9s. The book is greatly enlarged, is quite up-to-date, and includes the new Board of Trade Regulations issued February 6th.

NEW BOOKS AND EDITIONS.

The following New Books and Editions can be obtained of the Booksellers or direct from the Publishing Offices:—

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio price 12s. nett, or bound in strong cloth case price 12s. 6d. nett *(now ready)*. Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"THE WORK OF HERTZ."—By Dr. O. J. Lodge, with many original illustrations, price 2s. 6d. nett, is now ready.

Digitized by Google

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

"ELECTRIC MOTIVE POWER."—A new work, by Mr. Albion T. Snell with this title, is now ready, containing the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d. post free (abroad 11s.).

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by Messrs. W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—By Mr. F. Marten Weymouth is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.), Prospectus on application.

"PRACTICAL NOTES FOR ELECTRICAL STUDENTS."—By Messrs. A. E. Kennelly and H. D. Wilkinson, price 6s. 6d., post free.

"THE ART OF ELECTROLYTIC SEPARATION OF METALS."—A second issue of Dr. Gore's book is now ready, price 10s. 6d. post free.

"ARMATURE WINDINGS OF ELECTRIC MACHINES."—By H. F. Parshall and H. M. Hobart. This work has been compiled from Notes made by Mr. Parshall in his capacity as chief Designing Engineer of the Edison and General Electric Companies of America, and is intended to serve as a working treatise on dynamo design. Large 4to, 370 pages, 140 full-page illustrations and 65 full-page tables. 30s., post free.

"COMPREHENSIVE INTERNATIONAL WIRE TABLES FOR ELECTRIC CONDUCTORS."—By W. S. Boult, price 5s., post free.

TENDERS INVITED.—The Corporation of Sunderland invite tenders for steam engines, continuous-current dynamos, water-tube boilers, fuel economiser, water-softening plant, and cast-iron tank. Specifications, &c., can be obtained at the office of the Borough Electrical Engineer, the Electric Supply Station, Sunderland, and tenders must be sent to Mr. Fras. M. Bowey, Town Clerk, not later than 5 p.m. on Friday, the 13th March. Further particulars are given in our advertisement columns.

——— The Corporation of Bangor require tenders for the construction, supply and laying down of the necessary plant and mains for the installation and supply of electric current within the borough. The contracts are split up into two sections, and plans and specifications may be obtained from Mr. F. Hastings Medhurst, M.I.E.E., Westminster-chambers, 13, Victoria-street, London, S.W., after Monday next. Tenders must be sent in to Mr. W. H. Pritchard, Town Clerk, Bangor, by March 18th.

——— Tenders are requested by Mr. George White-Frazer, consulting electrical engineer, of 18, Imperial Loan Building, Toronto, Canada, for generators and motors to a total capacity of about 1,000 H.P. of each, in various sizes. The machinery is to be installed in a large paper mill in Canada. Our advertisement columns contain further particulars, and tenders should be forwarded promptly.

——— The London County Council require tenders for the supply of electric lighting sundries to Claybury Asylum for one year. Tenders to the Asylums Committee, 21, Whitehall-place, S.W., by March 4th.

——— The Corporation of Tunbridge Wells require tenders for the enlargement of their electric lighting station. Tenders to W. C. Cripps, Town Hall, by 25th instant.

——— The Metropolitan Asylums Board require tenders for providing telephonic communication, electric bells and fire alarms at the Brook Hospital. Tenders to the Brook Hospital Committee.

——— Tenders are being invited for building work, &c., in connection with the extension of the electric light station in Leeds. Tenders to Messrs. Milnes and France, 99, Swan-arcade, Bradford.

——— The Elberfeld Direction of the Prussian State Railways require tenders for the supply of the telegraph wire (iron and bronze) and porcelain insulators for the years 1896-9. Tenders to the Königliche Eisenbahn Direction, Elberfeld, by the 28th inst.

——— Tenders are invited by the municipal authorities of Mula for the concession for the electric lighting of the town for 50 years. Tenders to El Ayuntamiento de Mula (Murcia), Spain.

——— The municipal authorities of Herne invite tenders for the concession for the construction of a tramway to be operated by electric or other motive power between Herne and Recklinghausen (nearly six miles). Tenders to Der Verwaltungs-ausschuss, Herne, Germany, by March 18th.

——— The District Council of Chesterton (Cambs.) require tenders for lighting the district for seven years. Tenders to Mr. J. Spearing, 15, Sidney-street, Cambridge, by the 28th inst.

TENDERS ACCEPTED.—The tender of Messrs. Fellows and Wheatcroft, for fitting up the municipal baths for the electric light at £120, has been accepted.

TENDERS ACCEPTED.—The District Council of Swadlincote have received the following tenders for lighting the thoroughfares of Stanton by electricity:—

Hewes and Geary, Church Gresley, Burton (*accepted*)	£120	0	0
H. M. Edwards, Wakefield	186	10	0
Ellis and Ward, Birmingham	179	0	0
Ernest Scott and Mountain.....	157	0	0
Walsall Electrical Company	151	0	0
Electric Construction Company	145	0	0
Cutting Bros., Derby	119	0	0
Fletcher, Hirst and Co., Burnley	117	0	0

——— Four tenders have been received for wiring and fitting up "Bellevue," Southport, for the electric light for Sir G. A. Pilkington, J.P. The tenders varied from £283 (Mr. A. Maund) to £345. 3s. (Messrs. G. Hill and Co.), and Mr. Maund's tender has been accepted.

——— The Gas and Electricity Committee of the Bradford Corporation have decided to recommend the acceptance of the tender of Messrs. Sir John Brown and Co., Sheffield, for the supply of the boilers, fans, &c., for the electricity works.

———The Metropolitan Asylums Board has accepted the tender of the Private Wire and Telephone Installation Company for work in connection with the electric bell system at the Fountain Hospital.

LETTERS PATENT.—Particulars appear in our advertisement columns of a notice of application for leave to amend the specification of Letters Patent No. 4,554, of 1894, granted to Mr. Charles Adams-Randall for "Improvements in Telephony and Telegraphy."

APPOINTMENTS VACANT.—All whom it may concern are reminded that the applications for the post of electrical engineer to the Queensland (Australia) Government have to be sent in by Monday, March 2nd. All necessary information can be obtained from the Agent General for the Colony, 1, Victoria-street, Westminster, London, S.W., to whom applications have to be sent in. Further particulars are given in our advertisement columns.

——— The Professorship of Mechanics and Mathematics at the Royal College of Science is vacant. The commencing salary is £600 per annum. Applications to the Secretary of the Science and Art Department, South Kensington, S.W.

DIVIDEND.—It is expected that a dividend will shortly be announced in the failure of Samuel Elliott, electric casing and moulding manufacturer, timber merchant, and smoke annihilator. Those of our readers who are interested in the forthcoming dividend may take it for granted that the division will be very, very small.

FRASER V. SOUTH and SOUTH V. DADGE.—Mr. Harry South, of Garrick-street, Covent Garden, W.C., writes us in reference to the statement made by the Judge at the Westminster County Court, in which he described the Dadge partnership as a "juggle." Mr. South explains that the first action was lost by him more through carelessness than from any other cause, and as he has in contemplation further proceedings he invites others who (like himself and Messrs. Verity and Co.) have also been involved to come forward with information.

BANKRUPTCIES.—The first meeting of creditors in the bankruptcy of Charles Frederick Fox, electrical engineer, late of 14, High-street, and 1, Bond-street, Halifax, takes place at the office of the Official Receiver, Halifax, on the 24th inst., the examination at the County Court on March 9th.

——— Notice is given of the release of the trustee (Mr. G. Wreford, Bankruptcy Court, Carey-street) in the bankruptcy of Wm. H. Akester, electrician, 897, Fulham-road, London, S.W.

——— The discharge of Walter Andreae, 132, Hurlingham-road, Fulham, and lately trading as an electrical engineer at 47A, Lower Belgrave-street under the style of Walter Andreae and Co., has been suspended for two years.

——— A meeting is to be held at the offices of Mr. J. H. Buchanan, 8, York-place, Edinburgh, on March 5th, to consider the discharge of the trustee in the failure of Browning and Gardner, electrical engineers.

J. D. F. ANDREWS AND CO.—We are asked to state that Mr. J. D. F. Andrews on the 1st inst. severed his connection with the firm of this name carried on at Westminster, and has started in business on his own account under the same name at premises situate at Putney Bridge Station, London, S.W., where plant has been erected for the manufacture of a new wire specially devised for the Andrews system of concentric wiring.

REDUCTION IN PRICE OF ELECTRIC CURRENT.—The Directors of the House-to-House Electric Light Supply Company have decided to reduce the charge for current supplied for lighting purposes to 6d. per unit, from Lady Day next. The discounts now in operation are to be cancelled.

NEW COMPANIES.—We are asked to make a correction in the list of signatories to the General Construction and Tramroads Company (Limited), particulars of which were given in our last

Digitized by Google

issue. The name of Mr. William Mather should be substituted for Mr. Edward Mather.

OBITUARY.—We regret to announce the death, after only a short illness, of Mr. John A. Bird, Managing Director of Messrs. Rose and Bird, Limited, of Newgate-street, London. Mr. Bird had for some years taken a great and successful interest in the manufacture of incandescent lamps. He was only 41 years of age, and was at business but a few days back. He died on Friday last at his residence at Shortlands, Kent, and was buried on Monday at Hanwell cemetery. The cause of death was gastritis.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.—The fourteenth annual issue of this publication is now ready. The new volume is very up-to-date, and even contains the revised Board of Trade Regulations issued last week. The Directorial Section of the work is equally forward, and will be found to contain corrections and new names and addresses complete up to the 5th of the current month.

BATH.—At the meeting of the Town Council on Wednesday a report from the Electric Lighting Committee on their application for a Provisional Order, and their negotiations with the City of Bath Electric Lighting and Engineering Company for the purchase of their undertaking, was mentioned; but as a deputation from the Council and the Company were to meet and discuss the whole matter before the Board of Trade, the report was formally adopted without discussion.

BELFAST.—At the half-yearly meeting of the shareholders of the Belfast Tramways Company (Limited), last week, the Chairman (Mr. George Richardson) referred to the contemplated introduction of a system of electric traction on the Company's lines. He said the general tendency of all tramway companies was to discard horses in favour of electricity. It was an undisputed fact that in various Continental and American cities systems of electric traction were working in a most satisfactory manner, and had proved highly successful from a financial point of view. In order not to be behind the times, the Directors of the Company had gone into the whole question very carefully, and they had deposited a Bill in Parliament asking for powers to work their lines electrically. Mr. Richardson then referred to the attitude of the Corporation towards the Bill, and he thought they would be able to come to a mutually satisfactory arrangement as to the rent to be paid by the Company, the length of lease, &c. If not the Bill would be dropped.——In order to obtain information on the question of electric traction and to personally inspect some of the tramway systems at work on the Continent a deputation from the Belfast Corporation (headed by the Lord Mayor) this week visited Havre and Paris. At the former place the deputation were conducted over the generating station, &c, by M. Papeteray, the manager of the Electric Tramways Company. It is the intention of the deputation to also visit Brussels.

BOLTON.—At the last meeting of the Gas Committee the tender of the Manchester Edison-Swan Company for extensions to the switchboard at the electricity works was accepted. It was decided to make some extensions to the mains in Knowlsey-street and also to lay mains along the Manchester-road, and the tender of Messrs. Siemens, Bros. and Co. for the supply of the mains was accepted. The tender of the Brush Company for the supply of armature coils was also approved. The position of the electricity department is a highly satisfactory one, as there is at present an equivalent of 9,230 c.p. lamps connected. This is an increase of 100 per cent. for the past 12 months.

BRADFORD.—The Gas and Electricity Committee has decided to proceed with the extension of the electric light mains along Manningham-lane as far as Queen's-road, and has also decided to obtain for the purpose 25,000 high-voltage lamps similar to those in use at Edinburgh.

BRAY.—It is satisfactory to announce (and the statement will probably have an interest for the creditors of J. E. H. Gordon and Co. (Limited), in liquidation) that arrangements have been made under which the Bray Commissioners purchase from J. D. A. Norris, of Suffolk House, Laurence Poutney-hill, E.C., liquidator, the electric light works at Bray for the sum of £3,060. It is proposed to put in some new machinery and apparatus, and to bring the station up-to-date in its appointments. As a preliminary, the Commissioners propose to select a consulting engineer to report as to the condition of the works, and generally.

BRISTOL.—The Sanitary Committee have just presented a report on the application of the British Tramways and Carriage Company for a Provisional Order authorising the construction of tramways in the city of Bristol and at Kingswood. In addition to the construction of further tramways power is sought to work the whole of the existing lines by means of the overhead trolley system of electric traction as used on the Kingswood section. The Committee's report recommends the Council to sanction tramways 1 to 5 in the Order, but not to consent to a general power being conferred upon the Company to work the whole of their tramways by the overhead trolley or any other system of electric traction involving the laying of electric wires over or under the streets, or to erect power stations within the city, until further consideration shall have been given to the subject upon a definite proposal by the Company for so working the whole of their tramways within the city. The Committee further recommend that on certain conditions consent be given to the Company's application for power to work the tramways to Fishponds by means of the overhead system.—— At the last meeting of the Electrical Committee a long discussion took place on Mr. H. Faraday Proctor's report on the supply of electric current for motive power purposes. The Sanitary Committee having decided to recommend the Council to sanction an extension of the electric tramways from West-street to Fishponds-road, the Electrical Committee's report endorses this recommendation, but if any further extensions are to be made within the city boundaries the Committee will insist upon the Corporation supplying the necessary power. The matter is to be discussed at to-day's meeting of the Council. Applications for current for lighting purposes are increasing in a gratifying manner, and a surplus on the year's working, after paying all expenses, sinking fund, &c., is anticipated.

BRITISH NORTH BORNEO.—The *North Borneo Herald* a short time back contained an article on the value of small motors for launches. It is now suggested that electric launches should be used, a plentiful supply of water power being available for charging purposes. There are many rivers in the country likely to afford abundance of power.——In the same journal for January 1st an interesting account appears of the work done by Mr. O. V. Thomas, superintendent of Telegraphs to the North Borneo Government, in connection with the telegraph line in course of erection on the Government's territory, and which is to connect the Eastern Extension Company's submarine cable system at Labuan with Sandakan, the chief British North Borneo town. Mr. Thomas has traversed Borneo from east to west, being the first European to visit a large portion of the country. About 180 miles out of 305 had been erected up to November 14th last, and the completion is expected to be made by the end of June. Heavy floods have caused delay at times, but otherwise progress has been fairly satisfactory. Naturally the difficulties have been very great, the value of the rivers for transport purposes having been much over-estimated. In some parts the work has had to be done in a tract of country where no population exists, where there there is little or no food to be obtained, a way having to be cut through dense jungle, no road for transport existing. In connection with the urgent necessity for roads being made in order that the successful completion of the line may be effected, Mr. Thomas urges that in the more promising districts of Lumbawan and Sapong a good means of ingress and egress would undoubtedly pay, and he even has the temerity to suggest that an electric railway should be constructed. Mr. Thomas and his assistants are certainly to be congratulated on the result so far of their heavy labours, and we hope that that upon the completion of the line their work will meet with full recognition.

CARDIFF.—There always seems to be trouble at Cardiff, where circumstances seem to combine against the even working of the electric lighting undertaking. An inquiry was recently made by Mr. H. J. Hallett into the circumstances which led to the suspension of one of the assistant engineers at the electricity works, and Mr. Hallett's report recommends several alterations in the composition of the staff. He advises also that certain alterations in the machinery would render its working more efficient, There is, however, nothing serious to report, and the complaints made were, in the main, non-existent. The chief objection taken by Mr. Hallett is in the status of the mechanics under Mr. Appleby, the head of the works, who has under his immediate supervision a number of skilled mechanics, each of whom is possessed of certain ideas as to how the work should be done; and, as each has a comparatively free hand, confusion—to put it mildly—results. Mr. Hallett suggests that in future one of the four mechanics should hold a leading position, and this and some other suggestions have received the approval of the Council.

COATBRIDGE.—Notice of motion has been given for the next meeting of the Town Council for the appointment of a committee to consider and report upon the advisability of the Council purchasing the undertakings of the local electric lighting and gas companies.

COVENTRY.—At a recent meeting of the Electric Lighting Committee, Mr. Calcott complained that the cost of the electric light appeared to be greater in some cases than in others, and the Chairman (Ald. Hill), in reply, stated that, though no official complaints had been made, yet he thought there was some reason for dissatisfaction, but no blame could be attached to the Committee. The cause of the trouble here, as elsewhere, was that some of the consumers had been induced to put up cheap second-rate foreign lamps and fittings, instead of adopting the recognised standard fittings, which had always proved satisfactory. He concluded by stating

Digitized by Google

that the Committee or the electrical engineer would advise consumers on the question of fittings if applied to.

CROSBY.—The District Council have arranged with the Liverpool District Lighting Company not to oppose the Company's application for a Provisional Order for the district.

DUBLIN.—At the meeting of the Corporation on Monday last a long discussion took place on the electric traction question. Two proposals for the construction and equipment of electric tramways in the city had been submitted, that of the Dublin Southern District Tramways Company (owners of the electric tramway from Balls Bridge to Kingstown), being a very extensive one. On the advice of the city engineer, the Corporation approved of 13 miles of the Southern Company's scheme at an annual rental of £4,000, these terms to be subject to revision at the end of each term of five years. By 21 votes to 17 the principle of the overhead trolley system of electric traction was approved.

EXHIBITION.—The Deparment of Science and Art have been informed through the Foreign Office that a National Exhibition is to be held at Budapest this year. The Exhibition will be opened on May 2nd. As the Telegraph Conference is also to be held at Budapest this year, that city will have more than usual attraction for British visitors.

HAMPSTEAD (LONDON).—In the course of a discussion on the progress of the electric light at the last meeting of the Vestry, Mr. Farmer suggested the insertion of advertisements in the local papers and the issuing of fresh circulars calling attention to the advantages of the light, but the Clerk stated that it was impossible to connect any more customers at present, as they had reached the limit of the capacity of their plant. The Clerk is engaged in preparing a full report on the undertaking to the end of 1895.

HANLEY.—At a meeting of the Traders' Association last week Mr. G. Stokes called attention to the revised scheme of charging for electric current recently adopted in the borough. He took exception to the view that the revised rates would prove beneficial to traders except the large users, and suggested that if the Corporation wanted to benefit the traders they should reduce the price of current to 5d. per unit. He agreed that everyone should pay towards the electricity scheme, "for even those people who did not use electric current received benefit owing to the reduction (through the competition it caused) in the price of gas." If the price of electric current had been reduced to 5d. there would have immediately been a drop in the price of gas. A deputation waited on Mr. Lobley, the borough engineer, on the following day, when he was able to satisfy them that the revised rates were in the traders' interest.

HARWICH.—At the last meeting of the Town Council the Public Health Committee reported that they had considered the tender of the Town and Village Electric Lighting Company for putting down an electric lighting installation, but as the Company had withdrawn their offer to purchase the Provisional Order of the Corporation, they recommended that the negotiations be terminated. In moving the adoption of this report the Mayor said they had been given to understand that the Company were going to supply the plant, &c, but they had declined to do this. The initial outlay for plant would be so great that the Council were justified in retreating from the position they took up in November last. The report was then adopted.

HUDDERSFIELD.—At the last meeting of the Tramways Committee a letter was received from the London and Provincial Electric Lighting Company with regard to lighting the trams electrically.

HULL.—At a special meeting of the Electric Lighting Committee, last week, Mr. Councillor Skinner was elected Chairman of the Committee, *vice* Dr. Holder resigned.

LEITH.—The Town Council have appointed a special committee to consider and report upon the question of the establishment of the electric light works in the town.

LLANDRINDOD WELLS.—Some time ago the District Council entered into negotiation with Messrs. Jevons and Thomas, electric lighting contractors, of Birmingham, for the introduction of the electric light into the district. At the last meeting of the Council Mr. E. Davies, of Llandinam, stated he was prepared to form a company, who would provide an electric light installation, and to light the streets by means of 32 c.p. lamps at 40s. each per annum, against 58s. 6d. under the proposed contract with Messrs. Jevons and Thomas, while he would supply current for private lighting at 6d. per unit, against 7d. and 8d. under the contract. After a long and acrimonious debate it was decided to accept the proposals of Mr. Davies and to break off negotiations with Messrs. Jevons and Thomas.

LOCHEE (DUNDEE).—The electric light has just been introduced into the baths and library. A Parker dynamo is employed, and power is obtained from the engine which drives the laundry machinery. Three 1,000 c.p. Jandus arc-incandescent lamps illuminate the swimming bath; 19 16 c.p. and 3 50 c.p. incandescents are used in the library and reading room, and arcs of 1,000 c.p. each are fixed at the entrance door of the baths and library. The work of installation has been carried out by Messrs. James Maxwell and Son, of Dundee, and as this is the first public installation in Lochee it has aroused considerable interest.

LIVING PHOTOGRAPHY.—Accepting an invitation to a Press view of the "Cinématographe" at the Polytechnic, Regent-street, yesterday afternoon, we were agreeably surprised with the life-like movements of the different pictures shown upon a screen. The apparatus in question was invented by MM. A. and L. Lumière, and scenes of real life were reproduced. The photographs had been taken on a continuous band at the rate, it was said, of 900 views per minute, and by means of electric light these were projected life-size upon a large screen at exactly the same rate, so that a changing picture was produced almost perfect in its fidelity and naturalness.

MAIDSTONE.—The Town Council have decided to ascertain the feeling of the ratepayers as to the proposed transfer of the Maidstone Provisional Order to Mr. Thomas King, a local electrical engineer, and a public meeting is to be held on Friday next for the purpose of considering the question.

NEWPORT (MON.).—On the recommendation of the Electric Light Committee the Town Council have decided to make considerable extensions to the electric lighting mains.

PORTSMOUTH.—It has been decided to lay electric light mains in Goldsmith-avenue at a cost of £1,500, and to light the avenue by means of 28 lamps.

SHIP LIGHTING.—The new twin-screw Russian steamer "Kiew," which was launched from the yard of Messrs. J. and G. Thomson (Limited), Clydebank, on Tuesday, has, in addition to the usual electric light installation, with which nearly all steamers are now provided, been fitted with a very complete system of electrically-driven ventilating fans.

SHOREDITCH (LONDON).—The Finance Committee recommend the Vestry to borrow £31,381 from the London County Council for electric light and dust destructor purposes. An effort is to be made to obtain this sum at 2⅞ per cent. interest.

SOUTHAMPTON.—The County Council have resolved to offer the Southampton Electric Light and Power Company (Limited) the sum of £16,100 (in addition to the cost of the Provisional Order recently obtained) for the purchase of their plant, machinery, &c. In the event of this offer being accepted, the Council propose to considerably extend the electric lighting of the borough.

SOUTHEND.—We understand that the Pier Committee of the Southend Corporation have adopted incandescent gas lamps at the Pavilion and for lighting some portions of the pier. If it be true that this decision was come to owing to a supposed difficulty in obtaining high-voltage electric lamps, this difficulty certainly no longer obtains.

STOCKTON.—Some three months ago reference was made to the tardy progress of the electric lighting question at Stockton, and it was then stated that Mr. Ford, the experienced and talented manager of the Stockton Corporation Gas Works, has always held the view that "at any moment an invention might take place which would infinitely cheapen the lighting of towns by electricity." Mr. Ford still holds this view, and Stockton is without the electric light, although the Corporation recently appointed a committee to visit various Corporation supply stations with the view of reporting to the Council.

TAMPERING WITH FIRE ALARMS.—At the Eastern Police Court, Glasgow, on Saturday last, a man named Johnstone was fined £10, with the option of 60 days' imprisonment, for maliciously breaking the metal covering and glass of a street fire alarm.

TOLLERTON.—This is the name of a village a few miles from Nottingham, which may be termed progressive. It consists of a parish church, the manor house, and a few straggling houses; but, this notwithstanding, the electric light is in full operation in the village, the parish church and the manor house both being lighted electrically. The work has been carried out by Messrs. Thomas Danks and Co., of Thurland-street, Nottingham. The plant includes an oil engine and a battery of storage cells. At the manor house 200 16 c.p. lights are fitted.

TORQUAY.—At the special meeting of the Town Council, on Friday last, Mr. W. H. Trentham's report on the electric light question was discussed. Mr. Trentham recommended the Council to establish electricity works, and he estimated the cost of plant capable of supplying current to 4,000 16 c.p. incandescents and 70 arcs, buildings, &c., at £23,716. On the basis of a charge of 6d. per unit the revenue would amount to £4,322, and, on the presumption that the necessary power would be obtained from refuse

Digitized by Google

destruction, the working expenses were put at £3,234, thus leaving a net profit of £396, after allowing for interest, sinking fund, &c. The report was, after a lengthy debate, adopted by 15 votes to 3.

TRAMCAR LIGHTING.—Last week the I.E.S. Accumulator Company carried out some experiments in the electric lighting of tramcars at Plymouth. The experiments were made on cars belonging to the Corporation and the Plymouth, Stonehouse and Devonport Tramway Company. Two Ediswan incandescents were fixed at each end of the car, and current was supplied from an I.E.S. accumulator placed under the seats. It is stated that the trial proved very satisfactory, the light being good and unaffected by the jolting of the cars. It is claimed that after the initial cost the electric light is as cheap as oil, and, in addition, there is a great saving of labour in cleaning and attention.

WILLENHALL.—At the last meeting of the District Council it was decided to provide a system of electric calls between the fire station and the residences of the firemen at a cost of £70.

WORCESTER.—At the last meeting of the Watch Committee, on the recommendation of the Electric Lighting Sub-Committee, it was decided to erect 26 additional arc lamps in various streets of the city. The initial outlay for laying down the necessary mains, &c., is estimated at £1,850, and the annual upkeep charges for 26 lamps (which are to replace 74 gas lamps, 55 being double burners) will amount to £650.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

January 27, 1896.

1,848. C. ADAMS-RANDALL. London. Improvements in electric velocipedes and other vehicles electrically driven.

1,860. J. L. KENDAL. Manchester. Improvements in the method of and means for, protecting electric lamp fittings for corrosion and for preventing "short-circuiting."

1,867. S. W. BAYNES. London. Improvements in apparatus for straining electrical conductors in culverts.

1,888. S. Z. DE FERRANTI. London. Improvements in dynamo-electric machines.

1,905. H. MAXIM. London. Improvements in furnace blasts, and in process, and in means or apparatus for electro-thermally treating materials for the reduction of metals, production of carbides, acetylene, cyanogen, cyanides, nitrides, and the fixation of nitrogen.

1,927. M. L. WOOD. London. Improvements in electric railway systems.

January 28, 1896.

1,958. J. T. ARMSTRONG AND C. G. G. BRAUNERHJELM. London. Improvements in and relating to electric gaslighters and extinguishers and the like.*

1,963. S. GLOVER. Manchester. A new or improved electrical switch.

1,979. W. H. [illegible]. London. Improvements in conduits for conductors of electricity.

1,992. E. J. BAGNALL and G. ARNOLD. London. Improvements in electric arc lamps.

2,003. H. H. LAKE. London. Improvements in telegraphic repeaters. (B. F. Merritt, United States.)*

2,029. R. B. ROXBY. London. An improvement in electric glow lamps.

2,043. T. B. DIXON. London. Improvements in multiple telegraphy. [Date applied for under Patents, &c., Act, 1883, Sec. 103, 12th September, 1895, being date of application in United States.]*

January 29, 1896.

2,051. H. R. J. BURSTALL and H. F. W. BURSTALL. London. Improvements in electrical resistance thermometers.

2053. L. W. HEATH. Manchester. Improvements in so-called uni-polar dynamos for generating continuous electric currents, applicable also to continuous current motors and continuous current transformers.

2056. R. BRYAN-HAYMES, H. E. C. WALCOTT, J. B. COLLIER and E. G. BRYANT. Bournemouth. Improvements in and connected with magneto-electric machines for electrically lighting cycles and other vehicles.

2074. J. PARKER. Bradford. Improvements in the construction of lamp and bracket reflectors for electric, gas, and other lights.

2106. SIEMENS BROS. & CO., (LIMITED). London. Improvements in lightning discharges for electrical installations. (Siemens and Halske, Germany.)

2,107. J. IMRAY. London. Improvements in telephones. (La Société Anonyme pour la Transmission de la Force par l'Electricité, France.)

January 30, 1896.

2,161. P. DAWSON. London. Improvements in apparatus for conveying electric current from overhead conductors to motors on tramcars or like vehicles.

2,176. A. B. PINTO. London. Preserving meat by the help of electricity.*

2,194. O. BONDY and A. JORDAN. London. Improved means, applicable for use in electric arc lighting, for regulating the distance between the carbon points.

2,197. E. HERMITE, E. J. PATERSON, and C. F. COOPER. London. An improvement in the preparation of electrolysed chloride solutions for disinfecting and like purposes.

2,199. J. IMRAY. London. Improvements in apparatus for transforming alternating into continuous electrical currents, or conversely. (La Société Anonyme pour la Transmission de la Force par l'Electricité, France).

2,224. C. O. BASTIAN and H. C. HODGES. London. Improvements in prepayment mechanism for electrical or other meters.

January 31, 1896.

2,233. C. BÄKER. London. Improvements in the combination of writing tubes and incandescent lamps.

2,248. H. HIRST. London. Improvements in electrical cut-outs.

2,249. H. HIRST. London. Improvements in and connected with fuses for electrical cut-outs.

2,254. F. WALKER and W. C. SANDERSON. Barnsley. New or improved electrical appliance for extracting broken drills from bore-holes.

February 1, 1896.

2,324. J. H. TUCKER. Birmingham. An improved electric coupling.

2,328. J. B. BRUCE. Birmingham. Improvements in hanging lamps for gas, oil, or electric light.

2,335. W. MCWHIRTER. Glasgow. Improvements applicable to electric meters.

2,337. G. E. SAUTTER and H. HARLÉ. London. Improved means for use in working apparatus by electricity.

2,348. J. M. HUISMAN and H. C. GOVER. Glasgow. Improvements in electric switches.

2,382. H. H. LAKE. London. Improvements in dynamometers. (G. W. Lewin, United States.)*

February 3, 1896.

2,419. F. JONES. London. Improvements in electric pendulum indicators.

2,427. E. H. GRIFFITHS. London. An improvement in apparatus for measuring electrical resistances.

2,435. C. BUDERUS and J. MENZ. London. An improved dialytic process of decomposing salts and thereby creating electrical energy.

2,437. A. HIRSCH. London. Improved means of applying the heat of the electric arc for welding, soldering and other purposes.

2,447. MUIRHEAD AND CO. and F. L. MUIRHEAD. London. Improvements relating to telephones.

February 4, 1896.

2,501. A. S. KROTZ, W. P. ALLEN, and O. S. KELLY. Manchester. An improved system for conveying and furnishing electricity to railway cars and devices used in connection therewith.*

2,523. A. CASAZZA. London. An electric railway system.

2,545. H. H. Lake. London. Improvements in automatic current-regulators. (S. C. C. Currie, United States.)

2,570. W. A. HOUTS. London. Improvements in telephone systems.

2,581. E. W. SMITH and THE NEW PHONOPHORE TELEPHONE COMPANY Limited. London. Improvements in telephonic apparatus.

2,594. A. J. BOULT. London. An improved electrolytic process for extraction of caustic alkali and of hydrochloric acid from a chloride. (F. Villani, Italy.)

February 5, 1896.

2,610. E. S. G. REES. Wolverhampton. Improvements in the construction of dynamo electric machines and electromotors.

2,623. W. W. MCLAUCHLAN. Manchester. Electric targets and the like.

2,665. S. P. BLACKMORE. London. A new non-inductive adjustable carbon resistance.

2,666. J. E. PRESTON. London. An improved fluid for use in galvanic batteries and the like.

2,674. P. R. JACKSON and Co. (LIMITED) and J. S. LEWIS. London. Improvements relating to armatures for dynamo electric machinery.

2,683. G. HOOKHAM. London. Improvements in electricity meters.

February 6, 1896.

2,707. A. J. HOWARD. Taunton. Improvements in incandescent electric lamps, holders and the like.*

2,717. F. H. Royce and E. A. Claremont. Manchester. Improvements in controlling switches for dynamo-electric machines.*

2,745. B. M. Drake and J. M. Gorham. London. Improvements in apparatus for blowing organs by electric motors.

2,767. A. R. Bennett and G. J. Somerville. London. Improvements in telephonic systems and in switching apparatus for use therein.*

2,772. Siemens Bros. and Co., Limited. London. Method and apparatus for effecting the connection in parallel of alternate current and polyphase dynamos and motors. (Siemens & Halske, Germany.)

2,773. C. N. Ganzentes. London. Improvements in and connected with portable electric lamps.

February 8, 1896.

2,873. H. L. Doulton and C. E. Morris. London. Improvements in culverts for electrical conductors, and means of supporting the conductors therein.

2,875. H. H. Hall and W. D. Cheyne. Manchester. Improvements in or connected with electric incandescent lamps.

2,894. A. H. Webb. Glasgow. An improved electric alarm clock.

2,909. L. Falero and H. Lumley. London. Improvements in secondary batteries.

2,915. A. Czarnikow. London. An improved electric gas igniting and extinguishing apparatus.*

2,923. W. C. Johnson, L. J. Steele and J. W. Ewart. London. Improvements in alternate-current dynamos.

SPECIFICATIONS PUBLISHED.

Note.—All Specifications can now be obtained at the uniform price o 8d. each.

1895.

437. Barton (Jandus). Arc lamps.

527. Burstall and Hicks. Galvanometer, lamp, stand and scale.

1,202. Langdon. Telephonic apparatus.

1,536. Brown and Others. Electric motors.

2,303. Hermand. Electric lamps.

2,804. Imray (Diehl). Effecting electro-chemical decompositions.

3,087. Lake (Shea and Another). Telephone system.

3,521. Kamm. Printing telegraphs.

5,003. De Ferranti. Electric condensers.

5,086. Cox. Electric lamps.

5,236. Ravenshaw and Others. Starting electric motors.

5,336. Blackburn and Boyden. Dynamo electric machines.

5,521. March. Electric couplings.

5,936. Siemens Bros. & Co., Limited (Siemens & Halske). Electrically propelled vehicles.

8,148. Gisborne. Magnetic needles.

11,748. Hodgson and Edwards. Electric bell systems.

18,036. Leitner and Reicher. Battery electrodes.

19,374. Cox. Incandescent electric lamps.

19,838. Adams. Arc lamps.

22,006. Murphy and Pierce. Electric railway systems.

23,354. Le Roy. Electric heating devices.

23,658. Rosenholz and Poehlman. Electric railways.

23,865. Edison and Swan United Electric Light Company (Limited) and Proctor. Electric switches.

24,166. Edison and Swan United Electric Light Company (Limited) and Gimingham. Incandescent electric lamps.

COMPANIES' MEETINGS AND REPORTS.

Kensington and Knightsbridge Electric Lighting Company (Limited).

The ninth ordinary general meeting of this Company was held yesterday at 1, Great George-street, Westminster, Mr. Granville R. Ryder presiding.

The SECRETARY (Mr. R. S. Erskine) read the notice convening the meeting.

The CHAIRMAN: With regard to the year just passed I think the report and accounts afford sufficient evidence that there is plenty of vitality in the Company, and that our progress is steady and continuous. Our main mileage has increased by 1¼ miles in the course of the year; the houses and shops connected have increased by 201, from 908 to 1,109; the lamps supplied by us by 14,102, from 80,678 to 94,780; the sale of electricity by 250,977 units, from 977,789 to 1,228,734; and our net revenue has also increased from £9,289 to £10,988, an addition of £1,698. These figures are of a satisfactory character, but I have to point out that the comparison of the year 1895 with 1894 is not necessarily a very favourable one, because in the first half of 1894 the price charged was 8d. per Board of Trade unit, and during the last six months it was reduced to 6d., whereas during the whole of the year 1895 the price was at the lower rate. And I may add that during a considerable portion of last year, about five months, the reconstruction of the works was going on at Kensington after the fire in February of 1895, and the consequence was that our business was carried on with some difficulty, and the greatest credit is due to Mr. Crompton and Mr. Miller for having managed to keep things working so well while all these reconstruction works were going on. With regard to some of the items in the accounts I should like to say a few words and give a few explanations. There is an increase in the capital account which, I am afraid, will be an annual matter. It has increased in the year by £21,280, the greater part consisting of 4 per cent. debenture stock. The larger items on which that money was expended are these: £5,840 in the purchase of property. This was a purchase of some freehold premises close to our Kensington station, which are of very great advantage to the working of that station and have given us elbow room, which we very much required. The next large items are £7,350 for engines, dynamos and boilers, £1,351 for meters, £4,442 for mains, and £1,121 for batteries. These figures make together upwards of £20,000. Another point I wish to call your attention to is the very considerable sum carried forward as cash at bankers at the end of the year, £11,871. Well, that sum, which is a larger amount than we usually favour our bankers with, was owing to the fact that the Debenture stock issue had taken place in December, and the greater part of that £11,871 consists of the money subscribed for that Debenture stock. In the circular about that debenture stock which we sent to the shareholders, by whom it was entirely subscribed, we stated that the reason for issuing it was that we wanted to purchase some freehold properties. This purchase we carried out in January. The freehold properties in question was the frontage to our works at Knightsbridge, and consisted almost entirely of shops, and not only for the possibilities of future extensions, but also, as you are aware, with regard to manufacturing premises, it was a great thing to have considerable margin around you outside your works. I may add, with reference to these premises which we have brought, that the rents accruing from them are more than sufficient to pay the interest on the purchase money after making allowance for empties, insurance and repairs, so that they, will not stand us in anything at all in the way of loss of income. The next point I wish to call your attention to is the cost of the manufacture of electricity, the first item on the debtor's side of the revenue account. That amounts to £6,068, an increase of £927 on the preceding year, but that £927 has produced an increased output of 251,000 units, which has realised in cash £3,400, so that that is by no means an unsatisfactory item. All the things I have mentioned up to the present time have been of a pleasant nature, but there are sometimes disagreeable things at the bottom of the bowl, and the point to which I now wish to allude is of this kind and it is also one that refers to the future. I speak of our rates. A new assessment has been made, and although we fought the matter and obtained some reduction, the general result is that in future we shall have to pay four times as much in rates as we do now. Instead of our rates being about £500 per year they will be about £2,000. This is a very disagreeable thing, but we cannot help ourselves. Public companies in these cases appear to be at the mercy of the vestries, and so far as I can see there is no public opinion in our favour. As to insurance, I may say that our rate has been 5s. per cent. up to the present time, but that has now been increased to 10s. 6d. We shall do our best to find if it is not possible to get it reduced, but so far our efforts in that direction have not been successful. We now pay for insurance £236 per annum, but if we have to pay the increased rate it will in future cost us about £500 yearly. These are two standing expenses which we have to face in the future, and for which, so far as I can see, we shall get no return. One other point to which I will speak is the amount we have placed to the renewal fund and the sum we have provided to write off the item of goodwill. We have always felt that as we become more and more flourishing we ought to write down to some extent the more unsubstantial elements of our capital account, and as we rather think the goodwill comes under that definition, we have written off against that, £1,000. To the renewal fund we have placed the large sum of £4,270, after paying the whole cost of maintenance for the year, £2,208. That, of course, is a large sum, but I think it is very important that the renewal fund should be kept up. Electrical science is a progressive one, and consequently new things are constantly being invented to facilitate working, which it is necessary that we should possess ourselves of. Therefore it is extremely important that we should have a large sum in hand on that account to enable us to meet anything that may arise of that kind. I am sure that it is the right policy for the Board to pursue, and I hope you will agree with us in thinking so. These are the only points which occur to me as worth mentioning, but I shall be happy to answer any question. Mr. Hopkinson reminds me of another matter about which I might say a word, and that is with regard to the premiums we received on the issue of the debenture stock. As stated in the report, the Board thought that the best way of dealing with that money was to use it in paying the expenses and buying up the debentures, and you will observe in the accounts that the £755 received from premiums has been so applied. I will now move—

"*That the report and accounts now read be adopted and entered in the minutes.*"

Mr. G. H. HOPKINSON seconded the resolution.

Mr. WATERS congratulated the Board very heartily on the satisfactory progress made by the Company during the past year. If the Chairman could tell them conveniently, he should like to know what amount stood in their books for goodwill?

The CHAIRMAN: £14,000.

Mr. WATERS, continuing, said he believed the shareholders would appreciate the importance of placing a substantial amount to the renewal fund in order to put the Company in a position to take advantage of any improvements that electrical science might introduce.

Digitized by Google

Mr. NEVILLE asked how the amount arose for goodwill. He thought the Company was started as a new concern.

The CHAIRMAN: We bought up the Kensington Court Company, which was paid in shares.

Mr. NEVILLE, referring next to the conversion of the debenture bonds into Debenture stock, said he failed to see that it had been an advantageous financial transaction, as the Debentures were paid off at 105.

Mr. HOPKINSON explained that the Debentures were not redeemable at a less premium than 105, and in order to do so at the earliest date they had to give six months' notice in August last. Besides saving a certain amount of interest by the conversion they would be able to issue in the future Debenture stock at 4 per cent. or at a less rate of interest.

The CHAIRMAN then moved—

"That in respect of the Ordinary capital of the Company the interim dividend at the rate of 5 per cent. per annum paid for the half-year ending June 30th last be approved, and that a further dividend at the rate of 7 per cent. per annum be paid for the half-year ending December 31st last, payable on and after the 21st inst."

Mr. HOPKINSON seconded the resolution, and it was carried.

On the motion of Mr. HOPKINSON, seconded by Mr. NEVILLE, the Chairman was re-elected a Director.

Mr. CROMPTON then moved, and Mr. NEVILLE seconded, the re-appointment of the auditors—Messrs. Lovelock, Whiffin and Dickenson—at a fee of 50 guineas, which was agreed to.

On the motion of Mr. WATERS, seconded by Mr. NEVILLE, the Directors were voted £600 for their services during the past year.

A vote thanks to the Chairman brought the proceedings to a close.

Westminster Electric Supply Corporation (Limited).

The ordinary general meeting of shareholders of this Corporation was held on Wednesday at the offices, Eccleston-place, Eccleston-street, Belgravia, under the presidency of Mr. James Heslop Powell.

The SECRETARY (Mr. Frank Iago) read the notice calling the meeting, and the report of the Directors was taken as read.

The CHAIRMAN: I regret extremely that Lord Suffield is unable to be here to-day. He has suffered a very long and painful illness, but I am happy to say that he is now better and at Brighton, and able to get about, so that I hope we shall have him among us again before long to give us the benefit of his advice in the conduct of the business. I should now like to address a few remarks to you on the report and accounts, which I think must be considered satisfactory by every shareholder in the Company. They go to prove that the public has become aware of the advantages of electric light—that it not only gives the best illuminating power, but is accompanied by no bad air or undue heat to disturb the enjoyment of life or to injure the health of those who use it, which is not the case with all other illuminants. They further prove that the public believes our system to be safe, reliable, and inexpensive, and we believe it is capable of still further improvement. Not only do we find a considerable increase in the number of lamps newly installed during last year, but the increase in number steadily goes on. It has climbed up steadily from 167,703 installed on January 1, 1895, to 210,982 at the end of that year, giving an increase of 43,279 lights, and applications were received last month for 6,478 lights in addition. In the previous year the increase was not so great, being only 36,133 against 43,279 last year, and the consumers in the previous year were 526 more against 631 more last year. Therefore, both in the number of consumers and in the number of lights there has been a substantial increase, which is steadily maintained, although the field we draw upon has decreased. In January of this year we added 5,840 lamps. As may be expected, the capital expenditure has also increased, to the extent of £33,000, which is about 8 per cent. upon the previous capital; but then you have the very gratifying fact that our revenue has increased in a very much larger proportion—that is to say, our increase of revenue has been as much as 32 per cent. In 1894 our revenue was £53,407, and in 1895 it reached £70,511. Our net revenue has also increased very materially—as much as £12,410 on a capital expenditure of £33,000. The figures I quote to you are figures of increase and not figures of revenue. We regret to notice that the charge for fire insurance has increased. We have taken every possible means that we have of to make our buildings practically fireproof, and we have purchased and have on the premises every mechanical appliance known to us for extinguishing fire if unfortunately one takes place. We have also taken the further precaution of having our men periodically drilled in the use of these appliances. I may mention in regard to our revenue that the revenue per lamp is fractionally—only fractionally—higher than it was in 1894. The increase in our business is not spasmodic, it is all along the line; and whether we regard it from the number of units sold or from the number or class of our customers—the occupants of private houses and shops, the proprietors of clubs and of chambers, and hotel proprietors—or the gross revenue we receive from all these added together—all and each point to a general appreciation of a bright and safe light, which is a comfort to those who use it, and is the best preservative of internal decoration that has ever been presented to the public in the form of artificial light. This is a characteristic of electric lighting which should not be overlooked in calculating the cost of it. With respect to depreciation, our experience is that shareholders differ as to how much should be carried to that account. Some have gone out of their way—and we thank them for it—to write to us, commending our judgment in placing so large a sum to this account, and a few—a very few—having regard to how we have dealt with this item in the past, have expressed the opinion that the sum of £9,784 is an excessive amount to put by. The Board have not fixed on this figure by their own volition or as a matter of guess work, but have followed implicitly the advice of their eminent consulting engineer, Prof. Kennedy. He has divided the respective values of our plant and machinery according to their cost, and has allowed different percentages on each class, with a due regard to how they are likely to wear out. I have been personally warned that in the past our allowances were insufficient. My opinion on such a subject is worth very little, but I may say that I have seen in other undertakings very evil effects arise from not having carried right principles into practice in dealing with depreciation. In addressing you from this chair on a previous occasion, I explained that it was necessary to establish a sinking fund to provide for the recoupment of the money we had paid for our leases, and that we ought to have a reserve fund to provide against any contingency that might happen. I hope no misfortune will ever befall us that will require the use of such a fund; but should new discoveries antiquate our machinery, or some accident befall it, particularly at a time when the business life of the Corporation is coming to a close, and the Corporation may be unable to issue new shares advantageously, or to borrow on the security of our undertaking on low terms, a reserve fund—a real reserve fund, invested outside our business in first-class trustees' securities—will prove very useful to us. And even if no contingency arises or accident happens, such a reserve fund would be a very pleasant bonus for the shareholders to receive—something certainly not to be despised—at the end of our career. We have, therefore, invested a sum of £3,773 as the nucleus of a reserve fund, and £8,000 the premium on the new shares issued last year, and the interest already received on the investments. Interest and compound interest invested, and I hope some additions to the principal, will bring these funds to a very respectable sum in a short time. We have made some additions by purchase to our property. The property which we have lately acquired here and in Milbank-street adjoins our works, and will, when needed, be adapted for them. It was absolutely necessary in your interest that we should be possessed of this land before we required it immediately, for were our immediate wants known to adjoining owners, the price would have been raised against us. We are now independent of this. The property acquired here has been let for a term at a rental which is remunerative to us and fair to our tenants. I have now only to thank you for the patience with which you have listened to me, but I cannot conclude without expressing thanks to our consulting engineer for having steered us so safely through the many quicksands that were round about us in starting a new and, I may almost say, untried undertaking and to our manager for his energy and tact in dealing with the business of the Corporation. Without this co-operation of science and business, and, I may say, the valuable help given by our engineers, staff, and workmen, we should not have so early arrived at a time when we could declare a dividend at the rate of 9 per cent. per annum, and make all the needful provisions which I have described for the future to place this Company in a safe position. With these remarks I beg to move the adoption of the report.

MR. EDMUND BOULNOIS, M.P., seconded the motion.

The CHAIRMAN, in answer to a shareholder, stated that he had expressly said, in dealing with the question of the reserve fund, that they might add to it a further sum of principal. He could not, however, bind himself as to what the amount was to be, because the Board had not determined this question. He then put the motion, and, having declared it carried unanimously, proposed—

"That a dividend be declared for the half-year ended December 31, 1895, at the rate of 9 per cent. per annum, payable on March 1st next, making, with the interim dividend already paid, 7 per cent. for the past year."

Mr. J. BROWNE MARTIN, in seconding the motion, said he thought that everyone must be satisfied at the progress which the Company had made. They owned, he thought, the most wealthy district in London, and possibly in the world; and considering that electricity was simply in its infancy, he did not think there was the slightest probability of its going back. It must go forward. When they considered that the Directors had not made a single mistake in expending the shareholders' capital, either on experiments or other purposes, he thought it must be satisfactory to every shareholder.

The resolution was carried unanimously.

On the motion of Lord GALLOWAY, seconded by Mr. LESSELS, Mr. Powell was re-elected to his seat as a Director, as was also Mr. Martin, on the motion of Capt. GRANT, R.N., seconded by Mr. DARNTON HUTTON.

Sir MARK J. McT. STEWART, Bart., M.P., afterwards proposed a resolution that the Board of Trade auditor should act as auditor of the shareholders. He reminded them that the matter was discussed at their last meeting, and that the object of the resolution was to save the Company an expense of about 50 guineas, and to avoid the inconvenience of preening the books after they had been approved by the Board of Trade. It was the unanimous opinion of the Directors that it was not necessary to burden the funds of the Company with an expenditure upon auditors apart from the audit of the Board of Trade.

Mr. STRATTEN BOULNOIS seconded the motion, which was carried unanimously.

Lord GALLOWAY afterwards proposed a vote of thanks to the Chairman, Directors and staff.

Sir MARK STEWART seconded the motion, which was carried unanimously.

The CHAIRMAN, in acknowledging the vote, stated that they had all worked very hard to bring the Company to the position in which it now was. Mr. Browne Martin had said that the Directors had made no mistakes. Probably they had made some, but very few at any rate, and it was gratifying to the Directors to meet the shareholders under such pleasant auspices as on that occasion.

The proceedings then terminated.

House-to-House Electric Light Supply Company (Limited).

The eighth ordinary general meeting of this Company was held on Thursday at the Company's central station, Richmond-road, Kensington, Mr. William Page (Managing Director) presiding.

The SECRETARY (Mr. Thos. J. Owens) read the notice calling the meeting.

The CHAIRMAN: Gentlemen, the report is not a very startling one in any respect. There is nothing in it that is very exciting one way or the other. There are no very great things to report, and, on the other hand, there are no calamities to announce. Perhaps the most satisfactory thing is the continued increase in the number of connected lights, which have now reached 44,162 of eight candle-power each. The revenue, too, has gone up from £5,010 in 1890 to £15,394 in 1895, and it is still increasing. The number of lights connected last year was more than in 1894, and from the number of applications received since the beginning of the present year, we have every reason to believe that during 1896 the connections which will be made will exceed in number those of 1895. In the first six weeks of last year the number of applications was 831, while during the first six weeks of the current year it has been 1,420, so that although the increase last year was the biggest we had ever had we are doing a great deal better still this year, and that is a satisfactory feature. Unfortunately there has been an increase in the expenditure. For several years we kept the expenditure practically at the same level. In 1892, 1893 and 1894, although the output was greatly increased, we kept the expenditure quite steady. During the past year that has not been so, and there have been several reasons that we do not anticipate will occur again, at any rate not for some time, which have operated to bring this about. First, I may say, we carried out last year several expensive alterations in the works, among others the raising of one of our chimney shafts, and also alterations of the position of our plant, which we found to be necessary, and while this was being done the working department had to some extent to go to the wall. That is to say, we often had to run three units of plant when in the ordinary way two would have done the same work, and, of course that led to some of the extra expenditure. Another matter is that our system of having such a large number of converters distributed over the district, some of them being of rather an old type, it comes rather expensive. They take a great deal of current, but I may say that we are gradually changing them, banking the converters, and supplying, to some extent, the low tension; and as the result of this we expect to considerably decrease our coal bill. Even during the last week or two, since we have modified our working arrangements with the further plant we have had brought in, there has been a considerable saving shown in the coal bill; but I do not wish to say too much on this point, because as yet we have had only a short experience of the effect of these alterations. However, I may say that I shall be very dissatisfied if there is not a good many hundreds of pounds off the coal bill for the current year, although we shall doubtless supply a considerably increased quantity of current. So far as our reputation goes in the district, I think we stand very well as regards the steadiness of our light, for I have again and again heard that no other supply company in London equals ours in this respect. Certainly we go to a considerable expense to avoid anything like a breakdown, and we always manage to keep running. Of course, as has been mentioned more than once at these general meetings, we are in a district which is entirely residential, and that is not conducive to very heroic things in the way of returns; but we hope when we get our number of lights sufficiently increased that this undertaking will prove far more profitable than it is at the present time. We have added considerably to our plant during the past year, which enables us to look forward with confidence to our being able to meet any demand that may be made on us. Of course we should have to continue to add to our plant every year. The £1,800 spent for this purpose last year was, I think, disposed of by Mr. Bowden, our manager, with a great deal of wisdom, and in a manner which will be of great advantage to the Company. With these few remarks I will move—

"*That the report and accounts be adopted.*"

Mr. R. A. GERMAINE seconded the resolution.

The CHAIRMAN: I should have mentioned that I am sorry for the absence of our Chairman (Mr. H. R. Beeton). We quite expected until a couple of days ago that he would have been with us; but, unfortunately, he has been kept at home these last few days with sickness, and so is not able to be here to-day.

The resolution was then agreed to.

The CHAIRMAN: I now beg to move:—

"*That the remaining dividend on the Seven per Cent. Cumulative Preference Shares be declared and paid forthwith.*

Mr. FROST seconded, and it was carried.

The CHAIRMAN, in reply to a question as to whether all the shares of the new issue were taken up, said: I cannot say exactly how things stand, but a considerable number have been taken up. I daresay quite as many as we want at present.

On the motion of the CHAIRMAN, seconded by Mr. W. F. LEESE, the retiring Directors—Mr. W. R. Davies and Mr. R. A. Germaine—were re-elected.

The auditors—Messrs. Miall, Wilkins, Randall and Co.—were reappointed at a fee of 40 guineas per annum.

The proceedings terminated with a vote of thanks to the Chairman.

The Directors' report above referred to states that the revenue account shows a credit balance of £6,840. 16s. 1d. which, with £108. 11s. 5d. brought forward, £49. 11s. 8d., dividend on shares in the Yorkshire House-to-House Company, &c., makes a total of £7,011. 9s. 7d. After deducting £1,907. 18s. 4d. interest on debentures and £875 for interim dividend on the Seven per Cent. Cumulative Preference shares, the Directors recommend that the balance be dealt with as follows:—Reduction of preliminary expenses, £500; depreciation, £2,000; balance of dividend on Seven per Cent. Cumulative Preference shares, £875; reduction of construction business development account, £788. 11s. 11d.; carried forward, £64. 19s. 4d.; total, £4,228. 11s. 3d. The amount of £829. 9s. 4d. received as premiums on the issue of £10,000 Debenture stock is to be applied in further reduction of the construction business development account, making that item £15,000.

The progress of the Company's electric lighting business since 1890 is shown as under:—

Year.	Equivalent of 35 watt lamps connected.	Increase in 35 watt lamps.	No. of houses connected.	Gross revenue.	Expenditure.	Net revenue.
1890	13,665	9,145	248	£5,010 9 2	£4,624 6 5	£386 2 9
1891	19,388	5,723	373	8,328 3 11	6,077 14 10	2,250 9 1
1892	23,700	4,312	471	10,688 18 6	7,851 19 6	2,836 19 0
1893	28,429	4,729	599	12,063 10 10	7,832 6 8	4,231 4 2
1894	35,858	7,429	755	13,695 11 8	7,431 16 8	6,263 15 0
1895	44,162	8,304	932	15,394 16 11	8,554 0 10	6,840 16 1

The increase in the lights connected during 1895 was equivalent to 8,304 8 c.p. (35 watt) lamps, being the largest increase since 1890, the increase in revenue being £1,699. 5s. 3d., and in working expenses £1,122. 4s. 2d. During the year various alterations and additions to the plant have been made, which, it is anticipated, will tend to reduce the cost per unit of current in the future. £18,532. 8s. 9d. has been expended during the year on additional plant, mains, and buildings, and the expenditure for 1896 to meet the increased demand is estimated at £15,000. In order to provide for this outlay a further issue of capital is necessary.

With regard to the construction business development account, the Directors regret that they have been advised that the accounts of the Leeds and London Electrical Engineering Company (Limited), to whom this business has been leased, do not admit of the distribution of any profit.

During the year 1895 a further £10,000 of Four and a-Half per Cent. Mortgage Debenture stock has been issued, bringing up the total issue to £50,000, being the full amount created.

National Telephone Company (Limited).

The seventeenth ordinary general meeting of this Company was held yesterday (Thursday) at the City Terminus Hotel, Cannon-street, under the presidency of Mr. J. S. Forbes.

The SECRETARY (Mr. Albert Anns) read the notice calling the meeting, and the report of the Directors was taken as read.

The PRESIDENT, in moving the adoption of the report and the payment of dividends therein recommended, said: The report is made up mostly of figures, placed in such a way as to be easily understood, even by those whose business it is not to have to master very much the details of accounts; and the several paragraphs reveal all the essential facts to be known in order to appreciate the progress and position of the undertaking. There had been a substantial increase in the aggregate income of the Company during the past half-year—an increase of £43,860, which is equal to 11·58 per cent.; and the working expenses had increased by £11,344, or 5·52 per cent. The result is that the balance of profit available shows an increase of £29,231, which is equal to 21 per cent. The satisfactory feature there is that a larger income earned at a lower expenditure makes the greatest progress in percentage in the net income, and that is a combination which we shall all accept, no doubt, with gratitude. As I have said, the income of the December half of 1895, compared with that of the corresponding period of 1894 shows an increase of £43,860; but that is subject to a very considerable reduction in the nature of a 10 per cent. royalty to the Post Office in respect of all income earned from other sources than our private wires; and the Post Office [illegible] has increased in the half-year from £34,963 to £38,238. The net result of the half-year's working is a profit balance of £167,873, as compared with £138,642 at the corresponding period of 1894. The income was earned last half-year at 56·32 per cent. of the earnings, showing a reduction over the corresponding percentage at December, 1894, of 3·36 per cent. Debenture and other interest charges have increased from £26,437 at December, 1894, to £33,564 last half-year, but I daresay that you will not be alarmed at that increase when I tell you that the account has been charged in the last half-year with £7,126, being the interest on our reserve fund, whereas in the corresponding period of the previous year we had not yet commenced that method of dealing with the reserve fund. The Preference and Ordinary dividends, which depend on your confirmation to-day of our recommendations, will involve the payment of £96,593, or £12,114 more than at December, 1894, the increase being exactly the amount of the additional ½ per cent. dividend, which we propose to pay on the Ordinary shares. That leaves a balance of £35,000 to be carried to the reserve fund, and then it is proposed to carry forward £6,623, as compared with £3,379 a year ago. The item of rentals carried forward I must explain, and it is a very interesting and important one. It represents the amount of money paid by subscribers in advance in respect of periods not covered by the particular half-year under review. That is to say, a gentleman who begins on December 1, 1895, pays us a subscription in advance for 12 months, so we have to attribute to that month in 1895 one-twelfth of the amount of the subscription, the balance being carried forward. We, however, have that money in hand, and in that way we hold the considerable sum of

Digitized by Google

£354,635, which is £40,656 greater than at the corresponding period of last year. I have now given you the result of the past half-year's working as compared with that of the December half of 1894, but now I will draw your attention to the results of the complete years 1894 and 1895. Last year we had a gross increase in our revenue of £80,353; we paid the Post Office for royalties £7,451 more, and we had a net income of £744,360, showing an increase of £72,900. The working expenses show the moderate increase of £31,882, and the net result for 1895 was £320,195, or £41,000 more. The working expenses on the whole year diminished by 1·44 per cent. We transferred to the reserve fund in the year 1895 £70,000, or £11,517 in excess of the amount transferred to that fund in 1894. We have now to deal with an available balance of £138,217, and the Board recommend the payment of a dividend at the rate of 6 per cent. per annum, less income tax on the First and Second Preference shares, 5 per cent., less income tax, on the Third Preference shares, and 6 per cent. per annum, free of income tax, on the Ordinary shares. That 6 per cent. on the Ordinary shares opens a new state of things. Up to two or three years ago we paid 6 per cent. pretty regularly, but in face of the combinations of certain companies and of competition which threatened us, and in face of those sacrifices, which we perfectly foresaw, we should have to make in reference to the New Telephone Company, the Mutual Telephone Company, and all those combinations which were promoted and run in order to be bought off, we thought it prudent to restrain a little the dividend and to reduce it to 5 per cent. That was a prudential matter, which was fully explained to and acquiesced in by the shareholders. We have had nearly three or four years' experience of that lower dividend, and we are able now to estimate not only the probabilities in the expansion of our business, but also to discount with a little more accuracy the agitation that is continually going on in order to get up opposition to the Company. In the face of those combinations we have thought it prudent and proper to recommend the shareholders an additional ½ per cent. for the half-year. Under some circumstances the report would be considered meagre, but a difficulty presents itself when we have nothing to say. Paragraph 7 deals with a matter of great importance, for it tells you that the agreement with the Post Office--which has been a very long time about—has been executed by the Postmaster-General, and is now a valid and binding agreement on both parties. We are now waiting to be paid. As we say in the report, the sum is "practically agreed," and it is not only the amount which we are to receive in exchange for the surrender of our trunk wires, but many important matters of detail, involving considerable matters of principle respecting our future relations with the Post Office and the public, have been settled by discussion. We do not know what will happen, but what we hope is that the Post Office and ourselves will so work in harmony that the public will not find any very great inconvenience from the change which must ensue from splitting this business into two portions. We shall try to protect the public from any inconvenience from that cause. When our money is paid, which I understand will be very soon, we shall take it with a certain amount of thankfulness; but I suppose we should have preferred really, had it been anything but Hobson's choice, to have remained as we were. One cannot look very far into the future and foreshadow what will happen, but I suppose that by hook or by crook these trunk lines will be enormously increased as the benefit and value—the great commercial and social value—of the telephone become realised by the public. We long ago enunciated the common sense fact that the value of the telephone must depend on its more or less universality, and if our subscribers, in addition to the local use, for which they may primarily subscribe, are enabled to enjoy from year to year a great extension of the valuable and convenient depatch and receipt of telephonic trunk messages, it will make the local exchanges more valuable. We believe that, and it is to that we look as one of the sources of our future income and of the multiplying of our subscribers. We have not received an intimation of the acceptance by the Post Office of the figures in the form which would make it prudent for us to state them until we have them in black and white. I will therefore not commit myself to saying what the amount is, but it is a considerable and equitable amount. I do not propose to volunteer many criticisms upon competition that is talked about. I only know, when I hear so much [illegible] what is being done in Stockholm in connection with the telephone, that I lived there [illegible] It is a charming place, and one can get just as charming a house there for £50 a year as can be got in London for £500 a year; and all the conditions of life in Stockholm are subject very much to the same comparison. I daresay the telephone is very acceptable to people there at £6, but that is because that charge happens to be in proportion to the standard of values there. But Stockholm is not London. Yet we are repeatedly being told that someone is coming to London to give us a telephone for £5 or £6. We, however, will not delude ourselves that that is possible. I should be very sorry to be a party to inducing the shareholders of this Company largely to increase their capital in order that they might provide telephones in London or any great centre of commercial and social life for £6 or anything like it. We know something about this matter, and have had opportunities of learning a great deal; but when you come to meet these suggestions by the dreadful process of reducing them to facts and figures you see how fallacious they are. I therefore tell the shareholders not to be too much alarmed at the combination of defence, which is going on against the extortion, &c., of the National Telephone Company. Whatever arises we shall probably be prepared to meet it, and we shall meet it with this advantage—that we know the facts, and that certain hair-brained philosophers do not. Up to comparatively recent times people would not regard the telephone as a practical thing, but viewed it simply as a toy. That has changed now. We have already got 82,093 subscribers of a class who represent a great deal more in the active control of commerce than a great many hundreds of thousands of the ordinary population, and these 82,000 odd are growing from year to year at the rate of about 8,000 or 9,000, and we have to find a large amount of capital each half-year in order to take them on. Every subscriber who comes on costs so much money in connection with the instrument, the attachments, wages, and so on. In the past year we have increased our number of subscribers by 8,740, and I may say that the subscriber who has one wire pays the maximum charge—suppose we say £10, or in London £17 (it used to be £20). If, however, he takes a second wire he gets a reduction, and if he has a third wire he obtains a still further reduction, so that brings down the average subscription much below the maximum charge. In 1895 we spent in the year £337,905 in order to meet the demands of those 8,740 additional subscribers, and that works out at an average outlay of £38. 13s. 2d. per subscriber. Every man, in fact, who comes on to the system costs on the average, at the outset, from £38 to £40. In the past half-year, for our additional subscribers, we spent in this way £187,970, and that works out at an average of £41. 18s. 7d. He then went through the principal items in the net revenue account and balance-sheet, pointing out that the reserve fund amounted at the 31st of December £315,630, of which £279,545 had been reserved from profits, the balance being on premium account. The stock of materials amounted to £204,853, which seemed a large amount, but was really a comparatively small item when it became distributed in poles, wires, instruments and copper in many hundred places. He concluded with expressing great regret at the loss which the Company had sustained at the death of their late colleague, Sir Henry Calcraft.

The VICE-PRESIDENT (The Right Hon. Lord Harris), in seconding the motion, stated that when he joined the Board a few months ago he felt that he did so in a somewhat independent and critical attitude, owing perhaps to his having had something like ten years of public life. He thought that public criticism was a good thing, and he did not consider it was unnatural that the public, which was only beginning at present to take an interest in telephones, should take up a critical attitude. After all it was difficult to draw a very broad line of distinction between the telephone service and other services which were conducted by the Government of the country respecting which there was the utmost freedom of criticism both in the Public Press and Parliament. He rather welcomed public criticism, therefore, as it would stir them up to make their system as efficient as possible. That ought to be their object, and he hoped as they went on, and their knowledge of the instrument and its connections improved, they would be able very materially to improve their system. After all, however, as regarded criticism, it must eventually come down to £ s. d. The president had mentioned that they had about 90,000 subscribers, but the telephone was used by an infinitely greater number of persons in connection with those subscribers. The Company, a private body of shareholders—not the taxpayers --had conferred on the public all this great advantage, and he suggested that it was perfectly legitimate for them to reply to their critics that they must come down to £. s. d., and agree to pay a fair return on the capital which had been embarked in the undertaking. According to "Whitaker," the country had spent £11,375,000 odd upon the postal and telegraph service, including superannuation, as far as he could make out, and its receipts amounted to some £15,167,000 odd, or a profit, if "Whitaker" was correct in his figures, of £3,791,000 odd on the service as supplied by Her Majesty's Post Office. That, he thought, substantiated his argument —that men of business recognised that a profit must be paid to those who embarked their capital in giving a service such as the Company gave. Their representatives in Parliament had sanctioned these figures, which showed that the Post Office was worked at a profit, and surely that being so, they could not deny the same privilege to private persons. So far as he could see, every effort was being made to improve the service, and to secure the most efficient amount of work from the *employés* of the Company, whose services, he believed, were of the most loyal character.

The resolution was carried unanimously.

On the motion of Mr. CHAPMAN a cordial vote of thanks was passed to the President, Directors and staff.

The PRESIDENT, in acknowledging the vote, recognised the devotion and loyalty of their officers. There were certain annoying incidents which occasionally occurred in connection with the use of the telephone, but it must be taken for what it was worth, the same as anything else in life was taken. All they could do was to do the best they could to serve the public in connection with it, and they might rely upon it that everything would be done to render the service which they gave to the public as efficient as it could possibly be made.

The proceedings then terminated.

Northampton Electric Light and Power Company (Limited).

The annual report of the Directors of this Company states there is now an equivalent of 6,130 8 c.p. lamps connected, as against 4,600 in 1893, and 5,300 in 1894. The revenue, notwithstanding reductions in the price of current, has steadily increased, and amounted to £2,111. 7s. 11d. for the past year; the expenditure (including £250 for depreciation) came to £1,541. 11s. 7d., leaving a balance of £569. 16s. 4d. Of this sum £265. 16s. 8d. is to be applied in the payment of interest on Debentures, and £62. 1s. as interest on temporary loans, leaving a balance of £325. 11s. 2d. The Directors propose to pay 1½ years' dividend on the Preference shares to the end of June last. This will absorb £278. 8s., leaving £47. 3s. 2d. to be carried forward. The Directors state that they have been considering the question of further reducing the price of current and meter rents, and they hope to announce very shortly an alteration in the tariff. The report states that considerable additions to the plant and machinery will be necessary before next winter. Messrs. H. Manfield and W. Tomes are the retiring Directors, but seek re-election at the annual meeting to be held on Thursday next, the 27th inst.

Sulphide Corporation (Ashcroft's Process), Limited.

The statutory general meetiug of this Company was held on Tuesday last, at the Cannon-street Hotel, the Earl of Kintore, G.C.M.G., presiding.

The CHAIRMAN said: Although this is a statutory meeting, I am glad to say that such substantial progress has been made with this Company's affairs that I have several matters of interest to communicate to you. The whole of the share capital has been allotted. One of the first matters which occupied the attention of the Board was the engagement of gentlemen of first-rate ability and experience as heads of the several departments of the Company's business, and I am glad to be able to inform you that Mr. Ashcroft's services as technical manager have been secured for a period of two years. As the inventor and patentee of the process which bears his name, he will be able to render invaluable assistance in the erection of the Company's works, and in establishing them on a permanent basis. Mr. J. H. Smith (late Chairman of the South Australian Railway Commissioners), as Manager of the Company's London office, is a gentleman of the highest reputation in Australia for his powers of organisation and general business knowledge. Mr. H. H. Schlapp, late chief metallurgist of the Broken Hill Proprietary Company, who is intimately conversant with the Ashcroft process, has accepted the post of consulting engineer to the Company in Australia, and is at present co-operating there, with Mr. Ashcroft on this side, in the preliminaries connected with the erection of the Company's works. Dr. Schnabel (Royal Counsellor of the Prussian Mining Department) and Prof. Hampe (Professor of Chemistry at the University of Clausthal) have been retained as consulting chemists to the Company in Europe, and Messrs. Gibbs, Bright and Co., of Melbourne, have agreed to act as our Australian agents, under the instructions of the local Board, Messrs. J. S. Reid, Saddler and Keating. The property acquired by the Company consists of (*a*) patents securing the rights in the Ashcroft process for all parts of the world (exclusive of North and South America; (*b*) the Central Broken Hill Silver Mine in New South Wales, containing large deposits of sulphide ores suitable for treatment by the process; and (*c*) experimental ore reduction works at Grays in Essex, where the success of the process when worked on a commercial scale has been conclusively proved by a series of continuous trials carried on under the supervision of Mr. Fletcher Moulton, Q.C., Mr. Otto Stalmann and Mr. James Swinburne. With regard to the patents, they have been subjected to a searching examination by a committee of legal and technical experts, who consider their validity fully established, and the necessary assignments have been duly executed, vesting them in the Company, and our business will mainly consist in operating the process protected by these patents. Sites near Newcastle, New South Wales, seem to offer exceptional advantages for the erection of works, premises, being situated on the sea, with good port and harbour facilities, and having ample supplies of coal in the immediate vicinity. Newcastle has also the advantage of possessing good wharfage and railway accommodation, and an abundant supply of salt and fresh water. It is also a port of call and coaling station for steamers to and from all the leading Australian ports, so that freights can be easily arranged for, both in respect of plant and machinery and the Company's ores and products. The Board's final decision will largely depend on the question of price and the prospect of obtainiug special rates for the carriage of the various descriptions of traffic which will result from the establishment of these large works. We are advised that there will be no difficulty as to this, seeing that the works, when completed, will bring an addition of some 900,000 tons per annum to the railways of the Colonies. So soon as a site is definitely decided upon works will forthwith be erected in accordance with Mr. Ashcroft's plans. The plant will consist of concentrating, roasting, leaching and electrolytic machinery, arranged in "cyclic" order, so as to obtain the best and most profitable results with the greatest economy of time and labour and the least possible expense, both in regard to capital outlay and cost of maintenance. The material and machinery have been ordered from firms of the highest standing, under Mr. Ashcroft's personal supervision, and no pains have been spared to secure the utmost efficiency and reliability. The works, when completed to their full extent, will be of a capacity sufficient to treat a minimum of 5,000 tons of crude ore per week. It is intended, however, to erect them in sections. The thought and labour involved in the planning of an entirely new plant of such dimensions and importance can be readily understood, and the Directors desire to record their appreciation of the energy with which Mr. Ashcroft has applied himself to the task. The first section will probably be in profitable operation by the beginning of next July, and the second by the beginning of next October. As to the mine, this is situated on the main Broken Hill line of lode, which has in recent years yielded such large and valuable quantities of oxidised silver ores. In many of the mines these ores have been largely worked out, and the sulphide ores, which exist in very large bodies, have hardly as yet been worked, owing to their highly refractory nature having hitherto prevented their profitable treatment by any known method. The experts who reported on the Central Mine last year, after a careful examination of the property, estimate that in one chute only, between the 400ft. and 600ft. levels, there are upwards of a million tons of sulphide ore. At the 600ft. level "the deposit exists as a solid floor of sulphides," and as the Broken Hill sulphide bodies have been proved to a depth of 1,400ft., with strong indications of going deeper, you will see what a valuable property we have acquired, and its importance in furnishing us with a constant supply of raw material, and making us independent of outside sources. In conclusion, I have only to add a word or two about the experimental works at Grays. The object for which these were erected—namely, the demonstration of the success of the process when worked on a commercial scale—having been fully attained, they are no longer required and are therefore being closed down. A considerable portion of the machinery and plant is in course of shipment to Newcastle, New South Wales, to be installed at our works, and the remainder, together with the bullion produced at Grays, will be sold. I should mention that besides effecting the particular object for which they were erected these works have been very useful in two other respects. First, they have enabled Dr. Schnabel, of Berlin, to whom I have already referred as one of the Company's consulting chemists in Europe, to make a thorough personal investigation of the process in actual operation, his opinion being embodied in a highly favourable report. Secondly, the experience gained by their erection and operation will be of great value in putting up and running the Company's permanent works. I have now gone over the various points which the Board thought it would be of interest to you to hear, and I will just add the satisfactory news, conveyed by our latest advices, that arrangements have been made for the free use by us, if we require them, of two sections, measuring altogether 480ft., of the Government wharf at Newcastle for a period of 21 years.

On the motion of Mr. MATESDORF, seconded by Mr. G. WILLIAMS, a vote of thanks was passed to the Chairman, and the meeting separated.

India Rubber, Gutta Percha, and Telegraph Works Company (Limited).

The thirty-second ordinary general meeting of this Company was held yesterday (Thursday) at Cannon-street Hotel, Mr. S. W. Silver (Chairman) presiding.

The CHAIRMAN, in moving the adoption of the report, said: I may congratulate the shareholders on the result of the operations of the past twelve months. We have passed through a period of many changes, but they have not in the least affected the trade of the Company. The general business has been good throughout, and the electrical department has been fully employed in the erection of installations for several important cities, including Brussels. We have manufactured and laid about 300 miles of cable for the Cuba Submarine Telegraph Company, and this work has been acknowledged by that Company's engineer to have been carried out in a satisfactory way. This has given employment to two of our steamers. The works at Silvertown are well occupied. Since the commencement of the year 600 miles of submarine cable have been supplied to the satisfaction of the contractors and of the Japanese Government, and I may say that the amount in payment has been received by the Company. The factory in France is also well employed. In passing, I may just remark, as stated in the report, that acting on the suggestion of our vigilant auditor we propose before the next accounts are presented to make certain alterations in the Articles of Association as to the form of the balance sheet and profit and loss account which have been in use for so many years. In our late colleague, Mr. Henderson, we have lost one whose business capacity and sound judgment were of great value to the Company. I feel I need make no further comment, and now move the adoption of the report and accounts, and that the dividend of 7½ per cent. (or 15s. a share), tax free, be now declared.

Mr. ABRAHAM SCOTT seconded the resolution.

Mr. WRIGHT asked whether the item "Debts owing to the Company, £275,376," was about the average sum due at the end of the year, and how much of that sum was the auditor unable to certify. He asked that question because in his certificate the auditor reported that there were certain debts included in that item which he was unable to certify. Then as to "debentures and shares in other companies, £210,589," he should like to know what they were, because the auditor remarked that he was unable to certify as to the correctness of the value placed on them. Perhaps the Chairman would also say how the reserve fund was invested. With regard to the proposed alteration in the form of the balance sheet, he expressed the hope that, whatever form was adopted, it would be of such a nature as to enable the shareholders to form a better idea as to the affairs of the Company. He certainly hoped that the new form of accounts would give more information than the present ones did.

The CHAIRMAN: As there are no other observations I will answer very shortly the remarks which have been made by Mr. Wright. We are prevented from publishing more details, as by doing so we should supply valuable information to be used against us by our competitors. We are a trading company, and we have to be very jealous about what we say. As to the reserve fund, I may again remind you that, as has been stated from time to time, it is used as an auxiliary fund in the business.

The resolution was then carried.

Mr. MATTHEW GRAY (Managing Director) moved the re-election of the retiring Directors—the Chairman and Mr. Scott.

The Hon. HENRY MARSHAM seconded the motion, and it was agreed to.

The CHAIRMAN returned thanks in his own name and in that of Mr. Scott, and in doing so said: I cannot look forward to my appearance here for years to come, because I find a want of elasticity in my system such as should caution me not to exert myself even in the interests of this institution, which is very dear to me outside the mere question of pounds, shillings and pence. But I must remind you that as an industrial undertaking our success depends on the efficient state of the works as well as the judicious selection of materials, and last, but by no means least, the care exercised in the counting house. To these I trace to a great degree the success we have met with during the past year.

Mr. COCHRAN then moved the appointment as auditor of the firm of Turquand, Young, Weise, Bishop and Clarke. He observed that this year they were proposing to appoint Mr. Clarke's firm instead of himself personally, so that in the event of any unfortunate events there might be no break in the audit. Referring to the accounts, he said that in his opinion the shareholders were entitled to additional information, and pointed out that other trading companies gave it without having their interests adversely affected.

Mr. BLANKLEY seconded the motion, which was agreed to.

The CHAIRMAN, in acknowledgment, said: I may just say again that

Digitized by Google

we cannot see our way to extend the information given in the accounts without damaging the interests of the Company.

A SHAREHOLDER: Are the Directors satisfied with the valuation of the items in the accounts?

The CHAIRMAN: Perfectly.

The proceedings then terminated.

British Electric Traction (Pioneer) Company (Limited).

The first ordinary general meeting of this Company was held at Winchester House, Old Broad-street, yesterday (Thursday), Sir Rivers Wilson, G.C.M.G., C.B., in the chair.

The SECRETARY (Mr. T. Vincent Kitchener) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, as the secretary has just informed you, this is merely a statutory meeting at which no business will be transacted and no resolution proposed. It is a meeting called in conformity with the provisions of the Companies Act which requires that a meeting of the shareholders shall be held within four months of the registration of the Company. However, I will just give you a very short account of the proceedings of the Company up to the present time. It may be of interest to you who are present and to the many shareholders who are absent. You will remember that our capital is £100,000, and that 5,000 shares of £10 each were offered. Our friends responded very readily to the invitation to subscribe, and the amount asked for was subscribed many times over. I am afraid there was some little disappointment among some of the persons who applied for shares, but I can only assure you that the Directors did the very best they could, and made as fair and equitable a distribution as was in their power, looking to the very large number of applications made. I am happy to say that among the 165 shareholders that we have there are a number of very influential gentlemen connected with financial matters in the City and also many gentlemen of technical knowledge, whose experience will no doubt be at the service of the Company and be a great use to us. Since the date of allotment, November 19th last, your Directors have been very actively employed in pursuing the objects which the Company has in view. In the first place they have sought in various quarters for localities where the application of the electric traction system might be applied, and where the localities were anxious it should be applied. Then we have also turned our attention to other localities where they have at present certain methods of traction of what we may now call an obsolete character, and where it might be to the advantage of the locality to substitute electric traction for the more old fashioned system. Then we have also sought out for places where it might be possible to absolutely obtain possession by purchase of the existing obsolete systems, if I may so call them, with a view to the substitution of electric traction for these old methods. That is the three-fold division of the direction in which we have been working. Then to come from generalities to particulars, I will just mention that we are at present promoting a Bill in Parliament for the construction of electric trams from Kidderminster to Stourport, a distance of 3½ miles, an undertaking which will involve an expenditure of some £30,000 or £40,000. We are also promoting a Provisional Order for the construction of electric tramways from Oldham to Ashton and Hyde, a very important route, passing through a thickly-populated district in the neighbourhood of Manchester. I mention these two cases in particular, but you must not at all imagine that these are the only negotiations we have in progress. On the contrary, we have several very important negotiations connected with a variety of localities, but owing to circumstances which, I think, you will readily appreciate, it would be premature at the present moment to allude to them further. It is rather a delicate matter to carry on negotiations of this description, and you must leave it to the Directors at this moment without pressing for information. I can only tell you we have some very important matters in hand; but you know it is not always an easy matter to deal with municipalities and corporations, and overlaying, or overlapping, and often conflicting interests. You must take it from me that the two particular cases advanced to a public state do not constitute by any means the limit of the operations we have in progress. There is one matter in respect to which I am sure you will like to receive some information, that is the question of what shall be the system of electric traction which is likely to be introduced, and to become the system of the future. [illegible] present in operation, you have heard of the trolley system—the overhead trolley system—as to which a great deal may be said in its favour, but it has certain features of unpopularity and certain features also of inconvenience. The unpopularity is on æsthetic grounds and the inconvenience is with reference to its introduction in the crowded streets. My colleagues and I had quite recently an opportunity of seeing this system at work in what I may call its latest development at Bristol, and all I have got to say is that the æsthetic and the urban inconveniences are really reduced to a minimum. I should like to say that because the overhead trolley, owing probably to the extremely clumsy and inartistic manner in which it has been introduced in some foreign countries, notably in America, has become unpopular, which it hardly deserves to be if the system is properly carried out, and from the economic point of view—that is the Company's point of view—I will not say it is ideal, but has much to recommend it. However, we must not lose sight of the fact that there are these objections to which I have referred just now. Therefore we have turned our attention in other directions also. You are aware that there are in some places the conduit system, with the open slot. That also has its practical inconveniences, and it also has this paramount inconvenience, that it is extremely expensive. We are applying our minds most anxiously to this important subject. We believe we have acquired the right to a system, which is the result of the work of a most intelligent and eminent American engineer, which partakes of the nature of a closed conduit system, which will be unattended by any of the inconveniences I have referred to and will be extremely economical. I feel very sanguine I may say, but it hardly behoves me to ask you to share my sanguine expectations; but if these expectations should be realised as the result of experiments we are in process of inaugurating and which I hope will be carried out in the course of a very few weeks, I predict the very greatest possible advantage for the company which will succeed your pioneer company. I will just in conclusion remind you of what our Company is. In the first instance it is not—nor will the company which will succeed it be—a construction company. It is purely and entirely a financial company for promoting the objects I have alluded to; and our object is during our more or less short existence—I hope a very short existence—to set in train such a number of promising undertakings as will enable us to come forward in a very short time, comparatively speaking, and present a certain number of well-matured and promising undertakings, which may form the fie'd of operations of a very much larger company than our humble introductory pioneer Company. I cannot tell you at what date we shall be able to focus a sufficient number of these undertakings as the basis of a larger company, but in view of the work we have done and in view of the provisional engagements we have already entered into, and the expectation we have of forming others, I believe in a very short time we shall be able to offer attractions of a very remarkable character. That is my firm belief and expectation, which is shared by my colleagues. I think that really is the substance of all I need tell you to-day, but I should not be doing justice to my own feelings nor the feelings of my colleagues, who sit on my right and left, if I did not say how very much we owe, in all we have done, to Mr. Garcke, our managing director. I assure you I have some experience of public business myself, and of various descriptions of it and it, has never fallen to my lot to see more single-minded industry combined with intelligence than Mr. Garcke has devoted to your service and interests, and I assure you that having entered into this business with very little practical knowledge of the objects we had in view, I am emboldened to believe that I may continue to work this undertaking with every hope of success, in co-operation with our colleague, Mr. Garcke. I have no resolution to propose, and I can only thank you for your attendance to-day and hope that when we meet again we shall have something a little more substantial to put before you.

The proceedings then terminated.

Central London Railway Company.

The report of the Directors of this Company for the half-year to December 31st last, which will be submitted to the first half-yearly meeting of shareholders at the Cannon-street Hotel, E.C., on Wednesday next, at three o'clock, states that the sum of £506,420 has been received on account of shares, and that the amount expended up to the end of the half-year was £168,285. 6s. 2d., leaving a balance of £338,134. 13s. 10d.

The engineers have been engaged in negotiations with the local authorities respecting the details of the stations and other works, and the contractors (the Electric Traction Company, Limited) have proceeded, as far as possible, with the acquisition of the necessary land for the station sites, and a commencement will shortly be made with the actual construction of the railway.

Under Clause 28 of the Central London Act of 1892 an arrangement has been come to with the Waterloo and City Railway Company whereby, in consideration of a contribution by them to the cost of construction, and afterwards of maintenance, they will have access by a subway from their City terminus to the system of public subways to be constructed by the Central London Company in connection with their Central City station. This arrangement will facilitate the exchange of passengers between the two Companies.

The Board of Trade have given the necessary certificate relative to the payment of interest during the construction of the Railway, in accordance with the Central London Act of 1894.

The passing of the formal resolution sanctioning the issue of the capital authorised by the Act of 1892 does not involve any increase in the amount of capital offered for subscription in June of last year. Sir Francis Knollys and the Hon. Algernon H. Mills (Directors) offer themselves for re election, as does one of the auditors (Mr. Pannell).

MEMORANDA.—Bank rate, 2 per cent. (Feb. 22, 1894). Price of silver, 30 1/16d. per oz. (Feb. 20th). Consols (2¾ per cent.) 109⅞—110 for money, 109⅞—110 for account; 2½ per cent. 106½—107 (Feb. 20th). Stock Exchange Settling Days: Consols, March 2nd; Stocks and Shares Continuation Day, Feb. 25th; Ticket Day, Feb. 26th; Pay Day, Feb. 27th; Mining Share Carry-over Day, Feb. 24th.

LIVERPOOL.—At the meeting of the shareholders of the United Gas Light Company, held on Tuesday, Mr. A. B. Gilmour, who presided, referred to the increased consumption of gas. They had not advanced by leaps and bounds as in former times, but there had been a steady increase, amounting to between 2 and 3 per cent. The incandescent gas light was, in his view, becoming a rival of electricity—"It was a better, purer and more agreeable light than electricity." Notwithstanding the extended use of electricity in the district they were able to announce this increase in the consumption of gas. They were now, however, face to face with a more powerful form of competition in reference to electricity than before: the Corporation of Liverpool were entering the lists as their rivals, and they would have to meet this severe competition as best they could. One point would be remembered, and that was that electricity was not cheap, and therefore this competition was not likely to be so severe as would otherwise be the case.

Notting Hill Electric Lighting Company (Limited).

The Directors of this Company have issued their report to December 31st last, and this will be submitted to the meeting of shareholders to be held at the offices, Bulmer-place, High-street, Notting Hill, W., on Tuesday next, at 5:30 p.m. The report states that the expenditure on capital account to date is £84,038. 14s. 1d., the largest item in the current year's expenditure being for an additional battery of accumulators, which has been rendered necessary by the expanding business of the Company. The necessary capital has been obtained by the issue of Ordinary Preference shares, and owing to an increased demand for these shares, the Directors have been able to obtain a premium of £2 a share in recent allotments. The whole of the remaining unissued shares, amounting to £11,380, have been applied for at the same premium. The revenue account shows a profit of £3,227. 14s. 10d. compared with profits of £2,101. 17s. 8d. in 1894; £1,481. 7s. 1d. in 1893; £112. 6s. 1d. in 1892; and a loss of £554. 18s. 6d. in 1891. The number of lamps has increased from 15,669 in 1894 to 20,307, an increase of 4,688 lamps for the past year. The increases in 1892, 1893 and 1894 were 3,382, 2,715 and 3,516 respectively. The amount received from the sale of current shows an increase of £1,686. 12s. 2d., against £687. 4s. last year, and reached a total for 1895 of £5,881. 0s. 10d. Expenditure on repairs and maintenance was £780. 3s. 3d.

£700 has been set aside for depreciation and renewals, and after writing 3 per cent. off preliminary expenses, &c., a balance remains of £2,323. 9s., from which the Directors recommend a dividend of 6 per cent., less income tax, on the Ordinary Preference shares, £901. 17s. 2d., and 2 per cent., free of income tax, on the Ordinary shares, £1,290. 8s. 0d., carrying forward £137. 3s. 10d. The Provisional Order from the Board of Trade for powers of supply over the northern part of Kensington was duly obtained, and the Confirming Bill brought into Parliament; but, unfortunately, it had not passed through its final stages at the time of the recent dissolution, and it will therefore be proceeded with again during the present Session, no opposition being anticipated.

The Engineer and Manager, whose valuable services have before been referred to by the Directors, reports that the machinery, plant and mains are in good condition, and no accident of any kind has occurred.

Messrs. William Crookes and Sydney Waters offer themselves for re-election as Directors, as do the shareholders' auditors, Messrs. Fox, Sissons and Co.

Charing Cross and Strand Electricity Supply Corporation (Limited).

The report of the Directors of this Company for the year, to December 31st last, is issued, and will be presented at the meeting to be held at 2, Craig's-court, Charing Cross, W.C., on Monday next, at 12 o'clock:—

The Directors give a satisfactory report of the working of the Company for the year, and state that there has been a constant increase in the demand for current. On December 31, 1894, the Company were supplying current to the equivalent of 41,216 8 c.p. lamps, and on December 31, 1895, to 51,302 8 c.p. lamps, an increase of nearly 25 per cent., and 48½ per cent. over 1893. The supply station has been maintained in a high state of efficiency, but the Directors have decided to carry £3,000 to depreciation account.

The Provisional Order enabling the Corporation to supply electricity in the district of the Strand District Board of Works was granted by the Board of Trade, and the Bill confirming it passed a Committee of the House of Lords; owing, however, to the dissolution of Parliament, the Bill could not be dealt with by the House of Commons, by whom it will be considered in the present session of Parliament.

In view of the large increase in the business of the Corporation, a wharf and spacious premises, covering an area of 29,000 sq. ft., have been secured in the Commercial-road, Lambeth. The necessary alterations to render the premises suitable for an electric lighting station are now being made, and trunk mains laid connecting up the proposed station with the existing station of the Corporation at Maiden-lane.

The net earnings have amounted to £12,587. 3s. 11d. £700 has been written off preliminary expenses; £300 from law costs suspense account; £3,262. 10s. has been paid in respect of interest on Debentures up to December 31st last; and £2,899. 18s. 10d. was distributed in payment of an interim dividend at the rate of 4 per cent. for the half-year ended June 30th last. Out of the remaining sum of £5,729. 14s. 11d., it is proposed to pay a dividend (less tax) at the rate of £6 per cent. for the half-year ended December 31st, making, with the interim dividend paid in August, £5 per cent. per annum for the whole year (£4,350, 1s. 2d.), carrying forward £1,379. 13s. 9d.

Mr. Stefano Gatti and Mr. Richard Chadwick offer themselves for re-election as Directors, as do the auditors, Messrs. O. R. Johnson and Son.

HOOPER'S TELEGRAPH WORKS COMPANY (LIMITED).—Notice is given that all persons holding certificates of the bonus appropriation made in February, 1873, of the capital in the Great Western Telegraph Company (Limited), must apply at once to Mr. J. O. Chadwick (one of the trustees), 95, Finsbury-pavement, E.C., for the shares to which they are entitled of the proceeds of the above-mentioned bonus appropriation. The trustees retain the right of paying the balance remaining undistributed at the expiration of a calendar month from the 19th inst. into Court for the account of such claimants thereto as may appear and be admitted by the Court.

NEW COMPANIES, STATUTORY RETURNS, &c.

BROOK TIME-CHECKING CLOCK COMPANY (LIMITED).—This Company was registered on February 15th, with a capital of £5,000, in £1 shares, to acquire the invention of Mr. Frank Brook, for improvements in apparatus for checking or indicating the time of arrival and departure of workpeople, and also the business of a clock manufacturer carried on by the said Frank Brook at Market-street, Huddersfield, and to carry on the business of checking clock manufacturers, manufacturers of and dealers in electric batteries, electric clocks, and all electrical instruments and apparatus, electricians, &c. The first directors are: R. A. Robinson, Tom Brook, S. H. Robinson, A. Money, J. C. Arrol, Frank Brook and F. Marsland, all of Huddersfield.

ELECTRIC LIGHT INSURANCE AND MAINTENANCE COMPANY (LIMITED).—This Company was registered on February 14th, with a nominal capital of £10,000, in shares of £1 each, to enter into contracts for electric lighting and other purposes connected with electricity, for the supply of electrical energy for power or any other purpose, and for carrying out electrical installations, manufacturing, fixing, maintaining, selling, hiring or otherwise dealing with wires, lamps, secondary or storage batteries, and all other electrical appliances, and to enter into contracts and issue policies of insurance for the maintenance in proper order of all electrical appliances, and to repair and replace any of such appliances as may be defective or out of order. The subscribers, with one share each, are: W. M. Maxwell, T. C. Crawfoot, R. H. Webb, R. H. W. Hanna, W. Bowles, W. Webb and H. W. Webb.

HEADLAND'S PATENT ELECTRIC STORAGE BATTERY COMPANY (LIMITED).—The statutory return to February 12th has been filed. The whole nominal capital of £15,000, in £1 shares, has been taken up, and 14,993 have been issued as fully paid. The full amount has been called on the remaining seven shares.

WESTRALIAN ELECTRIC LIGHTING AND SUPPLY COMPANY (LTD).—The statutory return to January 23rd has been filed. Out of a capital of £80,000, in £1 shares, 70,000 have been taken up, and 40,000 are considered fully paid. The full amount has been called on 4,400 shares, and 10s. per share on the remaining 25,600.

WIMSHURST, HOLLICK AND CO. (LIMITED).—The annual return to January 3rd has been filed. The capital is £40,000, in 4,000 Ordinary and 4,000 Preference shares of £5 each. All the Ordinary have been issued as fully paid, and the full amount has been paid on 895 Preference shares.

CITY NOTES.

BRUSH ELECTRICAL ENGINEERING COMPANY (LIMITED).—The transfer books of the First Debenture Stock of this Company are closed from the 19th inst. to the 3rd prox. inclusive.

CITY AND SOUTH LONDON RAILWAY COMPANY, (LIMITED.)—The traffic returns of this Company for the week ended February 16th were £949, against £998 in the corresponding week of 1895, a decrease of £49. The total receipts for the half-year amount to £6,946, against £7,039 for the corresponding period of 1895, a decrease of £93.

GREAT NORTHERN TELEGRAPH COMPANY.—The coupons falling due on March 1st on the 1883 Debentures (Series B) of this Company, will be paid at the office of Messrs. C. J. Hambro and Son, 70, Old Broad-street, E.C., where lists may be obtained. Coupons must be left three clear days for examination.

ISLE OF MAN TRAMWAYS AND ELECTRIC POWER COMPANY (LIMITED).—Notice is given that the Directors of this Company intend to apply, at an extraordinary general meeting of the shareholders, for sanction to purchase the Snaefell Mountain Railway. The purchase money has been fixed at £72,500, payable in cash and shares. The capital of the Company is to be increased to £175,000.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended the 16th inst. amounted to £1,134. The amount for the corresponding week last year was £843. Increase, £291.

SANITAS COMPANY (LIMITED).—The Directors of this Company recommend the payment of a final dividend of 1s. and a bonus of 9d. per fully-paid share, making, with the interim dividend already paid, a total distribution of 13¾ per cent. for the past year.

STOCK EXCHANGE NOTICES.—Application has been made to the Stock Exchange Committee to appoint a special settling day in the shares of the Sulphide Corporation (Ashcroft's Process), Limited, and the Westralia Electric Lighting and Supply Company, Limited. The Committee have also ordered the further issue of £34,000 sterling Four and a-Half per Cent. First Mortgage Debentures (Nos. 1201 to 1540) of the Royal Electric Company of Montreal to be quoted in the official list.

TRAMWAYS UNION COMPANY (LIMITED).—The report of the Directors of this Company states, in reference to the circular addressed to the shareholders on July 1st last on the question of electric traction, that considerable progress has been made towards obtaining the necessary powers therein alluded to. A meeting of the shareholders of the Company takes place at Winchester House, on Tuesday next, at 2:30 p.m.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY, (LIMITED).—This Company's traffic receipts for the week ended February 14th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,818.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the half-month ended February 15th are £2,698, against £2,835 in the corresponding period of 1895. The October receipts, estimated at £4,257, realised £4,281.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861—1878.

No. 928. [No. 18. Vol. XXXVI.] FRIDAY, FEBRUARY 28, 1896. PRICE SIXPENCE.

NOTES.

QUITE by the way, and in answer to a hardy-annual type of question by a Mr. TULLY, the Secretary to the Treasury, as representing the POSTMASTER-GENERAL, made on Monday evening an important announcement in regard to the telephonic policy of the Post Office. It was not, he said, the intention of the Government to take over the entire telephone business of the country before the expiration of the National Telephone Company's licence on December 31st, 1911. That being so, we trust that in the interests of the public and of telephonic progress, the Post Office will, at any rate, permit a few experiments, such as a municipal exchange or a rural network erected by local capital. Between the dead-weight of an over-capitalised, over-grown company, and the lack of interest of an over-burdened Government department, we are in danger of an aggravated attack of telephonic torpor. We shall hope to see the Department rise superior to purely pecuniary considerations, and taking a large view of what constitutes "a satisfactory service," grant local licences with no niggard hand, even though the departmental income derived from that 10 per cent. levy on the gross receipts of the National Telephone Company might conceivably suffer a microscopic diminution.

DRY batteries have so many theoretical advantages that it is not surprising to find new types of cell being brought forward from time to time, which promise some superiority over their predecessors. Dr. LESSING's dry cell is one of the latest examples; and upon another page will be found a lengthy report on its merits by Dr. WALMSLEY. The misleading results that are liable to arise by testing only one cell of any particular type are well illustrated by the various measurements that are given of E.M.F. and internal resistance, which differ considerably among themselves. On that account it would have been preferable to test each cell separately rather than in groups of three in series. It will be observed that the internal resistance is initially low; but the polarisation appears to be somewhat rapid, and the life, when supplying a current continuously, is shorter than might have been expected. The cell, however, seems to be well made; it shows no sign of bursting when supplying a relatively large current, and would probably last well when used for intermittent work. The true commercial test, however, must be that of its life under ordinary working conditions, and this test cannot be more than approximately imitated by laboratory experiments, although these are of some interest in themselves. An ordeal which dry cells have not hitherto come out of very well is the very common one of being left to themselves for a few weeks or months; when called on to do a little work after a prolonged period of rest they too often fail to exhibit any signs of life whatever—a very irritating idiosyncracy.

IN last week's *Nature*, under the title of "Science and Morals," Prof. RAMSAY raises an issue of considerable and increasing importance. It is, says Prof. RAMSAY, becoming more and more the custom after the announcement of an interesting discovery, for a number of persons to at once proceed to make further experiments and to publish their results. To Prof. RAMSAY "it appears fair and courteous, before publication, to request the permission of the original discoverer, who probably has not merely thought of making identical experiments, but who has in many instances made them already, and has deferred publication until some grounds exist for definite conclusions." "No original idea undeveloped is," he truly observes, "of much value; before it produces fruit much work must be expended; and it is precisely after the publication of the original idea, that sufficient time should be allowed to elapse, so as to give the author time to develop his idea, and present it in a logical and convincing form." All this and much more may be conceded in a general way, but there is much that is vague in Prof. RAMSAY's phraseology, and having been bold enough to openly raise this delicate question, it would be as well if he were to go on and state definitely what he complains of in regard to his own invaluable researches on argon. Certainly we should not without Prof. RAMSAY's exegesis have given Prof. ARMSTRONG's remarks at the Chemical Society in 1894 the sinister meaning it is alleged they bear. As a precaution against scientific breaches of the eighth commandment Prof. RAMSAY thinks it may be necessary to make heavy investments in extra-strong laboratory locks and to abandon "the pleasant and friendly intercourse which is now universal" among scientific men.

HAS not Prof. RAMSAY mixed up two charges in his indictment? The eagerness with which any new scientific discovery is seized upon by pushing persons as a means of advertising themselves and of acquiring experimental fame at a cheap rate is, indeed, a well-marked and regrettable characteristic of the present day. But must not the blame for this

Digitized by Google

ugly symptom be in a measure laid at the door of the discoverers themselves? Do they not habitually indulge in premature publication of "original ideas undeveloped" in order "to take date"? "Sufficient time" for further development ought, of course, to be allowed even to the maker of the crudest suggestion, but who is to settle what is sufficient? Better by far to defer publication until one can safely defy interference. The second half of the indictment is decidedly more serious and more definite than the first, and the allegation is one that has been unpleasantly rife of late in the usual *sub rosa* fashion. It simply amounts to this: Such is the low state of morality in scientific circles at the end of the nineteenth century that an investigator cannot talk to a friend about that which most occupies his thoughts for fear lest his friend should straightway appropriate the germinating idea. If such breaches of social law are in truth as frequent as some would have us believe, we ought not to shrink from ostracising a prominent offender here and there; one or two examples would, in all probability, prove effectual.

In the tangle of facts and hypotheses which has collected round that thorny and attractive nucleus the essential reactions occurring in a common storage cell, much that is true or may be called good guessing is mingled with many dubious "facts" and untenable theories. A clue to the maze was thought to have been found when some persevering investigators discovered persulphuric acid in the electrolyte, and made known its properties to the electrical world. It was felt that a substance produced by the electrolysis of ordinary sulphuric acid, powerfully oxidising in its action and pleasingly unstable, was a very godsend. To the cautious student possibilities suggested themselves which were well worth the pains of experiment. Many investigations have been made from time to time, and much controversy has resulted. The latest word limits the scope of persulphuric acid in the accumulator in a marked degree. Elbs and Schönherr, in a Paper recently published in the *Zeitschrift für Electrochemie*, point out that experiments on the production of persulphuric acid performed with platinum electrodes cannot be used to foretell what will happen with lead electrodes. With the latter the yield is much smaller, the difference being indeed so great that no maker of persulphates (which are now articles of minor trade) would venture to substitute lead for costly platinum. Further, persulphuric acid is not only capable of peroxidising lead, but it may fulfil the opposite function and reduce lead peroxide The authors quoted deny in the clearest terms that persulphuric acid plays any significant part in the reactions of a lead storage cell, but they concede it a possible mischievous activity in destroying lead frames, presumably by its double-faced tendency to oxidise or reduce according to its company. To rehabilitate this substance a stout champion will be needed; he must, indeed, be *ion*-clad.

Our contemporary, *Nature*, a publication of irreproachable sobriety, has given modest space to a paragraph purporting to foreshadow the possibilities of an electrolytic method for making chlorate of potash, known by the name of the Blumenberg process. From this pronouncement we learn that the chlorate of potash is produced "by the action of the direct electric current upon tanks of potassium chloride"; that "important by-products are also obtained"; further, that the Alkali Union has reduced the price of the chemically-made salt "from 17 to 10 cents a pound"; while, lastly, there rings forth this knell of foreboding, that in spite of the spirited action of the Union "the new manufacturers will probably undersell them in all the markets of the world." That the application of the process is "another of the wonderful potentialities of the Niagara water power" goes without saying. For roundness and precision of statement the paragraph is exemplary, but as a means of slaking legitimate curiosity it is sadly lacking. Electrolytic processes for the manufacture of chlorate of potash we have always with us. One or two are even said to have survived their infancy, but as far as authentic information goes the market has not been wholly swamped by their output. Seeing that vast trade changes are said to be imminent—changes tending to the glory (and profit) of the electrolytic industry—we may perhaps be pardoned if we follow the good example set by Oliver Twist and ask for more wherewith to satisfy our curiosity as to the nature of the process and the status of its exploiters. Indeed, for the boldness of its predictions and the meagreness of its information, this paragraph would do credit to a latter-day prospectus.

As many enquiries are being made in regard to Sir John Pender's condition, we may say that, while his bodily health has improved, the power of speech and writing has not, so far, returned.

The Dalkey Electric Line.—On Friday last the inaugural trip over the electric lines, viâ Pembroke, Blackrock, Kingstown and Dalkey took place.

The French Association for the Advancement of Science.—The French Association for the Advancement of Science is this year holding its meeting in Tunis from April 1st to 4th next.

Röntgen Radiation.—The March number of the *Photographic Review* contains a large amount of illustrated literature, of the lighter and more popular order, dealing with the photographic side of the new radiation.

Cable Interruptions and Repairs:—

	Date of Interruption.	Date of Repair.
Puerto Plata—Martinique...	December 19, 1895 ...	—
Perim—Obock ...	... January 2, 1896 ...	Jan. 27, 1896
Odessa—Constantinople	... January 17, 1896 ...	Feb. 17, 1896

Appointments.—Prof. J. J. Thomson, F.R.S., has been elected Rede lecturer at Cambridge University for the present year.——Prof. Ramsay has been appointed an Elector to the Jacksonian Professorship of Natural Philosophy at Cambridge.

The Northern Society of Electrical Engineers.—The adjourned discussion on Mr. Robert Hammond's Paper on the "Paralleling of Alternators," read by him before this Society on the 10th inst. at Manchester, will now take place on Monday, March 9th, instead of Monday, March 2nd.

Electro-Optics.—A course of four lectures on "Recent Advances in Electro-Optics" is announced for delivery by Prof. Silvanus Thompson at the Finsbury Technical College on Thursday evenings in March. These lectures will deal with the experimental work of Hertz, Lodge, Tesla, Lenard, and Röntgen. Particulars will be found in our advertising columns.

Appointment Vacant.—Owing to the appointment of Prof. W. Wilson, M.A., as principal of the Municipal Technical School, Salford, the Professorship of Electrical Engineering and Applied Physics at the Merchant Venturers' Technical College, Bristol, will shortly become vacant. Commencing salary, £250

Digitized by Google

per annum. Applications by Tuesday, March 11th. Some further information is given in our advertisement columns.

The Hopkinson Three-Wire Patent.—The time for caveats in connection with the petition for the prolongation of the Hopkinson three-wire patent, due to expire in July next, terminated on Monday last. We understand that notices of opposition have been lodged by the Corporations of Glasgow, Hull, Bradford and Dundee, and by the National Electric Supply Company of Preston. The motion before the Judicial Committee of the Privy Council is not yet entered in the list, and cannot therefore be heard before Easter.

Electrical Bills in Parliament.—The total number of Electric Lighting Provisional Order Bills relating to England, Ireland and Wales before Parliament this session amounts to 38, the capital for carrying out these schemes being placed at about 1¼ millions sterling. There are 22 Tramway Bills relating to the construction of 103 miles of tramway, and the raising of capital to the extent of about 2⅓ millions sterling. In more than one-half of these schemes electric traction is contemplated. Besides the 22 Bills, there are 15 Tramway Provisional Orders asked for, in nine of which electric traction is specifically mentioned

The Jandus Arc Lamp.—We have received from Messrs Drake and Gorham a copy of a report of this lamp made by Prof. Houston and Mr. A. E. Kennelly. These gentlemen state that they found the average rate of burning of the positive carbon (½in. diameter solid) to be 0·057in. per working hour, and of the negative carbon (½in. diameter solid) 0·015in. per working hour. The average current was 5·60 amperes, and the power consumed at 110 volts pressure was 616 watts. The pressure between the carbons of the lamp when in operation averaged about 80 volts, and the resistance permanently inserted in the lamp effected a drop of pressure of approximately 30 volts, thus enabling the lamp to be used on a 110 volt circuit. They found the arc to be very quiet, and rarely to flicker. In measuring the candle power of this lamp, both globes were of clean and clear glass. The *maximum* candle power observed in any position was 1,295 standard British candles. For a detailed description of this lamp see *The Electrician* of November 1, 1895, p. 11.

Students' Conversazione at the Finsbury Technical College.—This *conversazione* which was held on Thursday, February 20th, proved a grand success. Perhaps the best part of the evening's entertainment was the lecture by Prof. Silvanus P. Thompson, on "Invisible Light and its Photography," which he had to deliver twice. Prof. Thompson showed various experiments with different vacuum tubes, and explained all about Röntgen rays. He actually took a shadowgraph of a few coins and keys through a piece of cardboard, and showed several of hands, feet, &c., which he had lately taken at the College. During the lecture he repeated the experiments of Prof. A. Righi, of Bologna, which were described in last week's *Electrician*. Amongst the exhibits were some automatic electric welders shown in operation by the Electric Welding Company. A number of samples welded by the process were on view, amongst which we noticed carriage tyres, butt-welded iron and steel tubes, samples of welded iron rods, bent double at the weld without cracking, and a good assortment of chains; also a unique collection of welds on finished gun parts, which is said to be quite a new departure. Mr. Robert W. Paul exhibited an apparatus for the production of "living photographs" thrown upon a screen by means of an electric lantern.

Expiring Patent.—On Friday next, March 6th, will expire patent No. 1,079, of 1882, granted to William Crookes, F.R.S., for "Improvements in the Construction and Manufacture of Incandescent Electric Lamps and in Apparatus used therewith." Among the claims are the following: "First: The production of carbon filaments for incandescent lamps from animal fibres such as silk, hair, wool, silk-worm gut, or animal matters such as horn or gelatine and parchment, by treating such materials with cuprammonia or other solvent, and then carbonising them. Second: The production of carbon filaments for incandescent lamps by the carbonisation of cellulose or like matter precipitated from solution in cuprammonia or other solvent. Third: The method of forming the junction between the carbon filament and the conducting wires by the use of a cement of graphitoidal carbon. Ninth: The process of improving and strengthening carbon filaments by depositing carbon thereon from a chloride of carbon or, it may be, a bromide of carbon. Twelfth: The method of at one operation equalising and measuring the resistance of carbon filaments, by arranging them in series and coupling them with resistances in a Wheatstone bridge arrangement, then applying an electric current, by which the filaments are raised to incandescence in contact with carbonaceous vapour, and continuing the current until it appears by the indicator of the arrangement that a balance has been obtained."

The Electrical Drying of Fruit.—There would appear to be a good opening for the use of electric heating in connection with the fruit trade. It is well known that fresh-gathered fruit must be dried before being packed. This process, although an apparently simple one, necessitates great care, and the temperature must be well regulated, otherwise there is danger of the fruit being damaged. Large drying rooms are in use in some cases, heated by means of steam, and although this system may be cheap to work on a large scale, it is not always so satisfactory on a small one. Fuel, moreover, is often expensive, and water power, in parts where the fruit trade flourishes, is usually abundant. In such situations electric heating could be used with advantage. The perfect regulation allows of any temperature being obtained, and, what is of great consequence in such an installation, practically no attention would be required. The electrical plant, too, could be used for lighting, and a few motors to aid the packing could easily be laid down. Uses such as this offer a fine field for development, and the gain made by bringing in cargoes of sound fruit would far more than cover the cost of running the necessary machinery. The above remarks have special reference to the storing, packing and shipment of fruit to the English market; but the same treatment as to drying might well be adopted in connection with our English fruit gardens, and it is quite possible that some such process might materially assist in making our orchards more profitable, and lead to extensions so much to be desired.

The Telephone in Parliament.—On Monday evening Sir J. Brunner asked the Secretary to the Treasury, as representing the Postmaster-General, whether it was the intention of the Department, after the transfer of the telephone trunk lines from the National Telephone Company, to close these trunk lines at the hours of closing of the various post offices, and thus to deprive a large body of subscribers of the convenience hitherto enjoyed by them of making use of the telephone at all hours of the night. Mr. Hanbury replied that from the best information in the hands of the Post Office it appeared that, except in a few cases, the telephone trunk wires were scarcely ever used at night, and the Department would not, therefore, be justified in going to the expense of providing attendance after the ordinary official hours. In the first instance, therefore, it was proposed that the hours for telephone business should be the same as for telegraph business; but the Department would give careful attention to the matter and ascertain where the requirements of the public justified an extension of the hours. At many of the larger offices the telegraph service was open to the public all night, and there, of course, the telephone service would also be open. ——On the same evening Mr. Tully asked the Secretary to the Treasury, as representing the Postmaster-General, whether he could state what steps the Post Office authorities proposed to take in reference to the numerous complaints as to the inefficiency and expensiveness of the telephone service supplied by the National Telephone Company; and whether it was the intention of her Majesty's Government to terminate the monopoly of this Company by taking over the entire telephone business as was done in the case of the telegraphs. Mr. Hanbury replied that if it were proved in any case that the Company were not affording a satisfactory service, the Government would be prepared to consider the question of the establishment of a limited competition by the Post Office. It was not the intention of the Government to take over the entire telephone business before the expiration of the Company's licence.

ELECTROMAGNETIC THEORY.—LXXXIII.*

BY OLIVER HEAVISIDE.

(*Continued from page 406.*)

§ 331. It is often to be observed that a property, first noticed in a special case, then in others, if it be really a general property, admits of simple proof. Perhaps the more general the property the simpler the proof. The last equation is an example. It is a particular case of the known reciprocal relation between the two solutions of the ordinary equation of the second degree. The proof is simplest in terms of V and C. Thus, let

$$-\frac{d\mathrm{V}}{dx}=\rho\mathrm{C}, \qquad -\frac{d\mathrm{C}}{dx}=\kappa\mathrm{V}, \tag{18}$$

be the connections. Here ρ and κ are, in the simplest case, the resistance of the wires and the conductance of the insulator, per unit length of circuit. They may be any functions of x. More generally they are operators, functions of p the time differentiator, when variable states are concerned, as well as functions of x. The characteristic of V is

$$\frac{1}{\kappa}\frac{d}{dx}\frac{1}{\rho}\frac{d\mathrm{V}}{dx}=\mathrm{V}. \tag{19}$$

Now let v_1, c_1 and v_2, c_2 be any two solutions subject to (18). Then, since

$$-\frac{d}{dx}(v_1c_2)=-v_1\frac{dc_2}{dx}-c_2\frac{dv_1}{dx},$$

we have, by (18),

$$-\frac{d}{dx}(v_1c_2)=v_1\kappa v_2+c_2\rho c_1. \tag{20}$$

Similarly,

$$-\frac{d}{dx}(v_2c_1)=v_2\kappa v_1+c_1\rho c_2. \tag{21}$$

Now if we make p be a constant, and the *same* constant in the two systems, κ and ρ become identical functions of x in the last two equations, so that the right members are the same. Therefore

$$\frac{d}{dx}(v_1c_2-v_2c_1)=0, \tag{22}$$

and consequently

$$v_1c_2-v_2c_1=m, \tag{23}$$

where m is constant. This is the reciprocal property.

If the two systems coexist, making $v=v_1+v_2$, and $c=c_1+c_2$ be the voltage and current, the product vc is the total energy flux, and its rate of decrease with x is its leakage, or the activity per unit length of circuit. It consists of the sum of the leakages from v_1c_1, v_2c_2, v_1c_2 and v_2c_1; and the reciprocal property in the form (22) asserts that the parts depending on cross products are equal. When p is real, the systems are real, and their energy, &c. When p is imaginary, the best way is to imagine it to be real, for the sake of the electrical argument. It is easy to generalise the property by extension to space distributions of electric and magnetic force, but we do not want that at present.

That p is to be the same constant in the two states, limits us to any two solutions of the ordinary equation which the characteristic (19) becomes, when the differentiator p is replaced by a constant. For example, ϵ^{qx} and ϵ^{-qx}, or combinations; $\mathrm{I}_0(qx)$ and $\mathrm{K}_0(qx)$, or combinations; and so on to other kinds. In terms of the v's only, the reciprocal property is

$$v_1v'_2-v_2v'_1=-m\rho, \tag{24}$$

where the accent indicates differentiation to x; and, in terms of the c's only, it is

$$c_1c'_2-c_2c'_1=m\kappa. \tag{25}$$

Thus (24) relates to the two solutions of (19), and (25) to those of the corresponding characteristic for c, which is not the same. If the two v solutions taken specially are in constant ratio, m vanishes, of course. When not in constant ratio, they are said to be independent. The independence is, however, of a limited nature, since, when one is given, another can be deduced by the reciprocal property.

§ 332. By means of the reciprocal property we are enabled to obtain the operational solutions for sources e and h. It will be convenient to denote two independent solutions by u and w, instead of v_1 and v_2, so that the property is

$$uw'-wu'=-m\rho. \tag{26}$$

Now there is a discontinuity at a source, so two forms of solution for the potential are required, say

$$\mathrm{V}_1=(u_x-\alpha w_x)\mathrm{A}, \qquad \mathrm{V}_2=(u_x-\beta w_x)\mathrm{B}, \tag{27}$$

where V_1 is on the left side of the source and V_2 on the right. These are operational, p meaning the time-differentiator, α and β unknown operators, A and B unknown time-functions.

Specialise the source to be h at y. This makes $\mathrm{V}_1=\mathrm{V}_2$, and $h=\mathrm{C}_2-\mathrm{C}_1$ at y. Applying these conditions to (27), using the reciprocal property (26), we produce

$$\mathrm{V}_1=\frac{(u_x-\alpha w_x)(u_y-\beta w_y)}{m(\alpha-\beta)}h, \tag{28}$$

$$\mathrm{V}_2=\frac{(u_x-\beta w_x)(u_y-\alpha w_y)}{m(\alpha-\beta)}h, \tag{29}$$

which are explicit when α and β are known.

When the source is e at y, which makes $\mathrm{C}_1=\mathrm{C}_2$ and $e=\mathrm{V}_2-\mathrm{V}_1$ at y, we similarly produce the results

$$\mathrm{V}_1=\frac{(u_x-\alpha w_x)(u'_y-\beta w'_y)}{m\rho(\alpha-\beta)}e, \tag{30}$$

$$\mathrm{V}_2=\frac{(u_x-\beta w_x)(u'_y-\alpha w'_y)}{m\rho(\alpha-\beta)}e. \tag{31}$$

The value of the constant m depends upon the standardisation of the functions u, w. It can be found as soon as they are given, by inserting them in the reciprocity equation. Only the commencement of the series need be used.

The operator α is determined by V/C at any point on the left of the source, and β similarly by V/C at any point on the right. Say $\mathrm{V/C}=-\mathrm{Z}_0$ at λ, and $=\mathrm{Z}_l$ at l, then

$$\alpha=\frac{u_\lambda-(\mathrm{Z}_0/\rho)u'_\lambda}{w_\lambda-(\mathrm{Z}_0/\rho)w'_\lambda}, \qquad \beta=\frac{u_l+(\mathrm{Z}_l/\rho)u'_l}{w_l+(\mathrm{Z}_l/\rho)w'_l} \tag{32}$$

By means of Z_0 and Z_l, we allow for the action of all the parts of the electrical system beyond the limits upon the part between them. That is to say, the operational solutions are complete for the region between λ and l, so far as the source e or h is concerned. The conversion to series of normal solutions is to be done in the usual way, and initial states of potential and current by $e=p\mathrm{P}$, $h=p\mathrm{Q}$, as before described.

Comparing the present investigation with that in § 330, we see that u is represented by $\mathrm{I}_0(qx)$ and w by $\mathrm{K}_0(qx)$, and that the constant m is $2/\pi\mathrm{Z}$. It is constant as regards x. It contains p (or may do so).

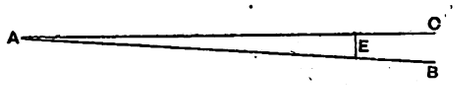
§ 333. Returning to the Bessel investigation of § 330, which contains most of the fundamental formulæ involving the zeroth Bessel functions of both kinds, by means of certain equivalent transformations we can develop the whole body of results, ordinary and extraordinary. But before doing that, it is desirable to point out that the formulæ are not merely those concerned in the theory of a telegraph line of a variable nature, of no practical use, but belong to cylindrical electromagnetic waves in general. Moreover, they do not do so by mere analogy, but, by proper interpretation of symbols, the two theories may be seen to be one and the same essentially.

Thus, I have shown in § 206, Vol. I., how, in the transmission of plane electromagnetic waves through a conducting dielectric, any tube of energy flux may be isolated from the rest and made independent, by enclosing it in a conducting tube made of two materials. The electric displacement in the tube must terminate perpendicularly upon perfect electric conductors forming two sides of the tube, and the magnetic induction upon perfect magnetic conductors forming the other two sides of the tube. Also, the electric force is tangential to the two magnetic conductors, and the magnetic force to the two electric conductors, whilst the two forces cross one another perpendicularly within the tube. Under these circumstances the internal plane waves are made self-supporting, guided by the tube. The internal state is like a beam of light, with lateral spreading prevented.

* This series of articles is a portion of Vol. II. of Mr. Heaviside's work on "Electromagnetic Theory." All rights of reproduction are reserved.

Digitized by Google

We may conveniently take the tube to be of square section for plane waves. Then the lines of force are straight. But in the present application, the tube must be imagined to be of the shape of a wedge. It increases in section regularly as we pass along it, but two of its flat sides remain equidistant, whilst the other two separate. Looking at the tube in section along its length, A B and A C represent the traces of the separating sides, to be called the top and bottom, whilst the others are parallel to the plane of the paper, and may be called simply the sides.



Now let straight lines of **H** join the sides, or be perpendicular to the plane of the paper. The **E** lines must then join the top and bottom, and be circular, centred at A, as at E in the diagram. Also, let E and H, the intensities of **E** and **H**, be the same at the same distance from A. Under these circumstances we shall have propagation of electromagnetic waves in the tube according to the formulæ given.

For, consider how the inductance and permittance of the tube vary. The current C is the same as H × depth of tube, being the transverse gaussage. The "potential" V, with an enlarged meaning of potential, is E × by length of arc concerned, or the transverse voltage. The inductance (per unit length of tube) varies directly as x, the distance from A, because the section of the tube of induction belonging to unit length of the tube of energy flux varies as x, whilst its length is constant. On the other hand, the permittance varies inversely as x, because the section of the corresponding tube of displacement is constant, whilst its length varies as x. The circuital equations are therefore

$$-\frac{dV}{dx} = Lxp C, \qquad -\frac{dC}{dx} = \frac{S}{x} pV, \tag{33}$$

if Lx and S/x are the inductance and permittance per unit length of tube, L and S being constants, the values of the same at $x=1$. The above makes no allowance for any conductivity within the tube, which is itself merely a guide.

Next, let the medium in the tube be uniformly conducting, both electrically and magnetically. Then the magnetic conductance will vary like L, that is, as x; and the electric conductance will vary like S, or as x^{-1}. We shall therefore make the circuital equations take the form

$$-\frac{dV}{dx} = (R + Lp)xC, \qquad -\frac{dC}{dx} = (K + Sp)\frac{1}{x}V, \tag{34}$$

if Rx and K/x are the magnetic and electric conductances per unit length of tube. So far is an exact theory. The reader should study Chapter IV., or the part relating to the transformation of the circuital equations in general to the special forms for plane waves along wires, and the interpretation of the quantity called magnetic conductivity. It is the same theory now, only applied to a tube of energy flux of variable section.

If we remove R from the inside of the tube, and substitute equivalent electric resistance in its top and bottom, the equations remain approximately true when the angle of the wedge is small, and the distance x not too great. It is now the theory of waves along a pair of finitely resisting electric conductors through an electrically conducting dielectric medium. If we remove K too, we must substitute equivalent magnetic resistance in the other pair of conductors, the side pair. But since K expresses a really existent property, it is no use doing that. Therefore retain K within the tube.

The depth of the wedge is immaterial. Make it infinite, and do away with the side magnetic conductors altogether. The wedge now consists of two planes (top and bottom) inclined at an angle. The magnetic flux is endless, which is equivalent to being circuital. If, now, in addition R is zero, the angle of the wedge becomes immaterial. This is also the case when R is not zero, provided it be in the tube of energy flux, and not at top and bottom. Increase the angle until it becomes 360deg. We may then remove the top and bottom plates altogether. The result is complete cylindrical waves in a conducting dielectric, the conductivity being of either kind or of both kinds, as we please. The voltage V is now circuital, and finite. The measure of C, on the other hand, is infinite. We need only, however, deal with a finite depth along the axis, when C will be finite too.

But in § 330 the resistance of the wires varied as x^{-1}, and the permittance as x. To obtain this case, we have merely to interchange the electric and magnetic forces in the above. The magnetic force must be in the plane of the paper in the figure, and parallel thereto, and be circular. The electric force must be straight and perpendicular to the paper. So, to begin with, the sides of the tube must be perfect electric conductors, and the top and bottom perfect magnetic conductors. Then, if the medium in the tube is uniformly conducting in both ways, the quantities K and S will vary as x, and the quantities R and L as x^{-1}.

The same substitutions of resistance in the bounding conductors for the internal conductance may be made as before, allowing for the change in position of the electric and magnetic forces. Also, the bounding conductors may be wholly removed, leaving complete cylindrical waves in a homogeneous dielectric, conducting in either or both ways. The gaussage C is now reckoned once round the circle of magnetic force. To make V finite we may consider only a finite depth along the axis.

We see that the problem of a telegraph circuit has real application to electromagnetic waves of much greater generality than plane waves, by letting the "constants" of the circuit be variable. The process employed is not confined in its application to cylindrical waves. Spherical waves may be similarly treated, by employing a tube whose section varies as x^2, both pairs of sides separating. Both **E** and **H** will be along arcs of circles, centred at the axis. In fact, the theory of this case is much simpler than the other, but we must not run away from the matter immediately in hand.

§ 334. After the enlargement of ideas of the last section, we may partially discuss some of the operational results. Notice first that the results for ρ in § 330 are produced from those for h, by substituting $eqy(d/dqy)$ for Zh. We may keep at present to the h set. Thus, take equation (14), or

$$V_1 = \tfrac{1}{2}\pi Zh\,\frac{(I_{0x} - \alpha K_{0x})(I_{0y} - \beta K_{0y})}{\alpha - \beta}, \tag{35}$$

giving V_1 at $x<y$ due to h at y. Interchange x and y when V_2 is wanted.

If l is infinity, K_{0l} is zero, and β is infinite, by (12). This reduces (35) to

$$V_1 = \tfrac{1}{2}\pi Zh(I_{0x} - \alpha K_{0x})K_{0y}. \tag{36}$$

We see that the terminal condition at l becomes impotent, and disappears.

Again, if $\lambda = 0$, $K_{0\lambda}$ is infinite, and $\alpha = 0$, by (12). So

$$V_1 = \tfrac{1}{2}\pi Zh I_{0x}\left(K_{0y} - \frac{I_{0y}}{\beta}\right). \tag{37}$$

Thus the terminal condition at λ becomes impotent and disappears by shifting it to the origin. Also note that in the region reaching to the origin, K_{0x} does not appear. It is usual to consider that we cannot have the K_0 function in solutions extending to the origin (the axis of the cylinder in cylindrical waves), unless there is a source at the origin, because to do so would make V infinite there. That this reason is inadequate and unsatisfactory will be evident if it be allowed that V can be infinite at the origin without having a source there, of which I will give examples. That is, we obtain infinite results at the origin without using K_{0x}. Nevertheless, there is no doubt that the K_0 function is excluded unless there is a source at the origin, as we saw above, unless there can be something very peculiar about the Z_0 operator, making α, which is given by

$$\alpha = \frac{I_{0\lambda} - (q\lambda Z_0/Z)I_{1\lambda}}{K_{0\lambda} - (q\lambda Z_0/Z)K_{1\lambda}}, \tag{38}$$

be finite when $\lambda = 0$.

[Equation (12) contains misprints. α is as just written, and β is got by changing λ to l and $-Z_0$ to Z_1.]

If both $\lambda = 0$ and $l = \infty$, then $\alpha = 0$, $\beta = \infty$. Both terminal conditions are impotent, and

$$V_1 = \tfrac{1}{2}\pi Zh I_{0x}K_{0y}, \qquad V_2 = \tfrac{1}{2}\pi Zh I_{0y}K_{0x}, \tag{39}$$

which represent an important fundamental solution.

Digitized by Google

If $y=\lambda$, we have only the V_2 solution under control, and

$$V_2=\tfrac{1}{2}\pi Zh\frac{I_{0x}-\beta K_{0x}}{\alpha-\beta}(I_{0\lambda}-\alpha K_{0\lambda}). \quad (40)$$

If $y=\lambda=0$, we reduce the last to

$$V=\tfrac{1}{2}\pi Zh(K_{0x}-\frac{I_{0x}}{\beta}) \quad (41)$$

The source is at the origin, and the Z_0 condition is impotent.

Finally, if $l=\infty$, $\beta=\infty$, and (41) reduces to

$$V=\tfrac{1}{2}\pi Zh K_{0x}. \quad (42)$$

Thus, with the source at the origin, we have the K_0 function alone if there is no reflection, but the I_0 function as well when there is reflection at a finite distance, as in (41).

Similarly as regards e. By (9),

$$l=\infty \text{ makes } V_1=\tfrac{1}{2}\pi qye(I_{0x}-\alpha K_{0x})K_{1y}, \quad (43)$$

$$\lambda=0 \text{ makes } V_1=\tfrac{1}{2}\pi qye I_{0x}(K_{1y}-\beta^{-1}I_{1y}), \quad (44)$$

$$l=\infty\ \lambda=0 \text{ make } V_1=\tfrac{1}{2}\pi qye I_{0x}K_{1y}, \quad (45)$$

$$y=\lambda=0 \text{ make } V_2=0. \quad (46)$$

In the last case the finite e produces no disturbance beyond the origin, because of the vanishing conductance there. In (42), on the other hand, h is given to be finite. That it needs infinite impressed voltage is immaterial.

§ 335. The above results are usually operational. But they are strictly numerical results in certain cases, without change of form, or perhaps with only nominal change. Thus when the source gives rise to a steady state we can use the above at once. Putting $p=0$ makes $q^2=RK$, which is constant. Then I_{0x}, &c., are all algebraical functions and are numerical when x is given. So, knowing the general nature of the curves I_0 and K_0, we can see by inspection in some cases the nature of the steady states on both sides of the source. We have, of course, when α and β are concerned, to make Z_0 and Z_l represent the steady resistances terminally at λ and l.

In these direct numerical applications, use the formulæ (4) when qx is small. But they are quite unsuitable when qx is big. Then use the approximate formulæ

$$I_0(qx)=\frac{\epsilon^{qx}}{(2\pi qx)^{\frac{1}{2}}}, \qquad K_{0x}=\left(\frac{2}{\pi qx}\right)^{\frac{1}{2}}\epsilon^{-qx}, \quad (47)$$

which show plainly how the functions behave ultimately. The quantity $8qx$ should be several times unity to make (47) be practically true. More generally, use the formulæ

$$I_0(qx)=\frac{\epsilon^{qx}}{(2\pi qx)^{\frac{1}{2}}}\left(1+\frac{1^2}{8qx}+\frac{1^2 3^2}{\lfloor 2(8qx)^2}+\frac{1^2 3^2 5^2}{\lfloor 3(8qx)^3}+\ldots\right), \quad (48)$$

$$K_0(qx)=\frac{\epsilon^{-qx}}{(\frac{1}{2}\pi qx)^{\frac{1}{2}}}\left(1-\frac{1^2}{8xq}+\frac{1^2 3^2}{\lfloor 2(8qx)^2}-\frac{1^2 3^2 5^2}{\lfloor 3(8qx)^3}+\ldots\right). \quad (49)$$

The first terms represent (47). These are divergent formulæ, and, to obtain the proper values, stop when you reach the bottom, and ignore the rest. That is, seek the point of convergence of the series you are calculating, or the place where the smallest term occurs. The error is limited by the size of the smallest term, and may be far less, especially if half the smallest term is counted. The above are the practical formulæ except when qx is so small that the smallest term may be big enough to introduce a large error. Even when qx is as small as 1, the error is not very great. It is when the point of convergence, which is at a distance along the series when qx is big, comes to the beginning of the series, that we are obliged to go to the convergent formulæ (4). The difference between the divergent and convergent series is, for numerical calculation, only one of degree, and the degree varies. In the convergent series, the point of convergence is always at the end of the series, which cannot be reached. But the terms at the end tend to zero in size, so that by taking enough trouble we may reduce the error to be smaller than any quantity that can be named. But then, when qx is big, a very large number of terms must be counted before we come to the convergent region, so the convergent formulæ are unpractical. On the other hand, if $8qx$ is greater than 1, the divergent formulæ are convergent from the very beginning, and allow of rapid calculation with an accuracy which is practically unexceptionable when qx is a large number, and of fair approximativeness so long as the point of convergence is not too near the first term. It is a question of practice which formulæ to use. The connections between the convergent and divergent formulæ will be given in Chapter VII., as well as their connections with other formulæ. There is a table of the I_0 and I_1 functions (and others) in Gray and Mathew's work on Bessel functions, p. 282, going up to $qx=5{\cdot}1$. After that (48) may be used, or even (47), noting that I_1 is the derivative of I_0. But I cannot find any table of the important K_0 function, and therefore use (49) myself, or else (4), to get rough values.

Since, as has been said, the above formulæ become numerical where steady states are concerned, it is not necessary to rewrite them, with $\sqrt{RK}$ substituted for q, to indicate the special results. Observe, however, that should either R or K vanish, or both vanish, the formulæ simplify considerably, when steady states are concerned, and it will not be a bad thing for the reader to look into a few cases in detail, both with q finite first, and then with $q=0$, by the vanishing of R or K.

Look at (39) for example. The constant impressed current h at y produces V as there given, with $q^2=RK$ in the I_0 and K_0 functions, and $Z=R$. Now, if R is zero, V is zero on both sides. The corresponding current is $C_1=0$, on the left, and $C_2=h$, on the right side of the source. That is, when $Z=Lp$ and $Y=Sp$, representing the case of no waste of energy by resistance, h all goes to the right ultimately, and there is no electrification. The absence of electrification is the striking point. It is really a case of statics, or of motional statics. The setting up of the steady state involves electromagnetic waves, of course, but they all disappear ultimately.

(To be continued.)

THEORY AND CALCULATIONS OF ASYNCHRONOUS ALTERNATE CURRENT MOTORS.

BY A. HEYLAND (BUDAPEST).

(*Continued from page 508*).

III.—A. *Normal Load.*

We have defined as *normal load* the case, when the difference of phase ϕ between the primary current I_1 and the primary tension K is a minimum, ϕ_{min}, and further, for this case, $\cos(\phi_{min})=(\cos\phi)_{max}$ as *maximum power factor f*.

Let f be given for the design of the motor.

(1) *To determine the coefficient τ from the maximum power factor f.*—Fig. 7 again illustrates the conditions of normal load. A C″ is tangent to the circle described about O_c; C″ A B is ϕ_{min}, so that $\cos C''AB=\cos(\phi_{min})=(\cos\phi)_{max}=f$. Since now O_cC'' is perpendicular to A C″, and O_cA to A B, angles C″ O_c A and C″ A B are equal, and as $OC''A$ is a right angle, we find $\frac{C''O_c}{O_cA}=\cos C''O_cA=\cos C''AB=f$. C″ O_c is as radius equal $\frac{CD}{2}$; A O_c is $AC+CO_c=AC+\frac{CD}{2}$, and therefore, equation (9),

$$f=\frac{\frac{CD}{2}}{AC+\frac{CD}{2}}=\frac{1}{2(1+\tau)^2-1}=\frac{1}{1+4\tau} \quad (10)$$

We thus arrive at the interesting conclusion that the *maximum power factor of a polyphase motor depends simply upon the dimensions of the iron masses, and not upon the resistances of the circuits.*

We further develop

$$\tau=\sqrt{\frac{1+f}{2f}}-1. \quad (11)$$

$$\tau\equiv\frac{1-f}{4f}. \quad (11a)$$

Digitized by Google

(2) *To determine the relations between I_1, I_2 and I, f being given.*—For the case of normal load, all the angles may be expressed by ϕ_{min}, as has been done in Fig. 7, from which we derive

$$\frac{AC''}{AC} = \frac{\cos\frac{\phi_{min}}{2}}{\sin\frac{\phi_{min}}{2}} = \sqrt{\frac{1+\cos(\phi_{min})}{1-\cos(\phi_{min})}},$$

that is,

$$\frac{\text{primary current } I_1}{\text{magnetising current } I} = \sqrt{\frac{1+f}{1-f}} \quad . \quad . \quad . \quad . \quad . \quad (12)$$

Further,

$$\frac{C''C}{AC} = \frac{\cos(\phi_{min})}{\sin\frac{\phi_{min}}{2}} = \frac{\cos(\phi_{min})}{\sqrt{\frac{1-\cos(\phi_{min})}{2}}},$$

that is,

$$\frac{\text{secondary current } I_2}{\text{magnetising current } I} = \frac{f}{\sqrt{\frac{1-f}{2}}} \quad . \quad . \quad . \quad . \quad . \quad (13)$$

(3) *To determine the dimensions of the motor from τ and f.*—τ has been defined by the equations (3A), (3B), (7),

$$\frac{h_1}{H} = \tau_1\frac{I_1}{I}; \qquad \frac{h_2}{H} = \tau_2\frac{I_2}{I}.$$

Therefore

$$\tau_1 = \frac{\frac{h_1}{I_1}}{\frac{H}{I}} = \frac{\frac{h_1}{H}}{\frac{I_1}{I}}; \qquad \tau_2 = \frac{\frac{h_2}{I_2}}{\frac{H}{I}} = \frac{\frac{h_2}{H}}{\frac{I_2}{I}}; \qquad \tau = \frac{\tau_1+\tau_2}{2}.$$

Referring to one phase of a polyphase system, h_1 signifies the sum of the stray fields per circuit and pair of poles, H the main magnetic field per pair of poles.

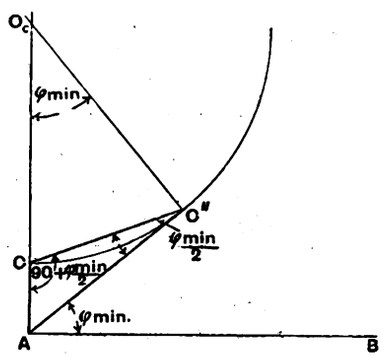


FIG. 7.

Fig. 8 illustrates the winding for one phase of a six-pole triphase motor with drum armature; the other two phases have not been marked. For our stray field h_1 per circuit and pair of poles we can substitute a number of stray fields h_1' h_1' . . . surrounding each groove. If we have z grooves per pair of poles and m phases, there will be to each phase winding $\frac{z}{m}$ grooves and $\frac{z}{m}$ stray fields, h_1' per pair of poles. To each winding we have to reckon two stray fields h_1' connected in parallel. Let there be w turns per phase and pair of poles; let I_1' be the amplitude of the current per phase, and $\rho_{h1'}$ the magnetic resistance of each stray field h_1'; then the *magnetising force* of the turns of a pair of grooves will be

$$\frac{4\pi}{10} \cdot \frac{\frac{w}{z}}{2m} I_1' \quad . \quad . \quad . \quad . \quad . \quad (14$$

and the stray field

$$h_1' = \frac{4\pi}{10} \cdot \frac{\frac{w \cdot 2m}{z}}{\rho_{h1}} \quad . \quad . \quad . \quad . \quad (15)$$

Reckoning to each turn $2h_1'$ in parallel, we have

$$2h_1' = \frac{4\pi}{10} \cdot \frac{\frac{w \cdot 2m}{z}}{\frac{\rho_{h1'}}{z}}$$

These stray fields h_1' h_1' . . . constitute h_1, which is produced by the total ampere-turns of a phase per pair of poles.

Then

$$h_1 = \frac{4\pi}{10} \cdot \frac{w \cdot I_1'}{\frac{\rho_{h1'} \cdot z}{4m}} \quad . \quad . \quad . \quad . \quad (16)$$

The magnetic resistance of this field will be

$$\rho_{h1} = \frac{\rho_{h1'}}{2} \cdot \frac{z}{2m}, \quad . \quad . \quad . \quad . \quad . \quad (17)$$

$$h_1 = \frac{4\pi}{10} \cdot \frac{w \cdot I_1'}{\rho_{h1}} \quad . \quad . \quad . \quad . \quad (18)$$

h_2 will be determined in the same manner.

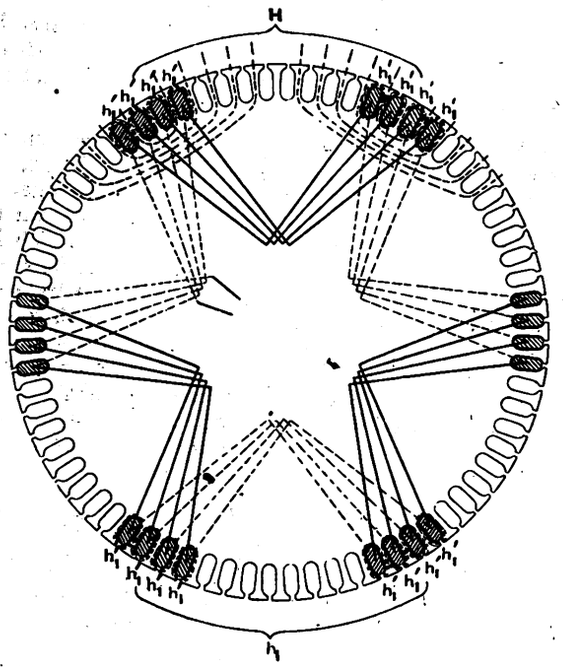

FIG. 8.

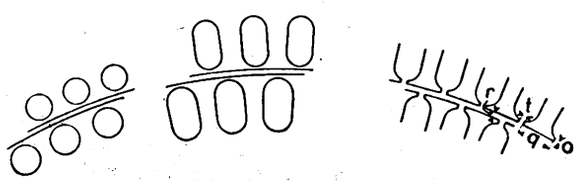

FIG. 8A. FIG 8B. FIG. 8C.

H, the main field, is produced by the combined action of the m phases as represented by the magnetising current of the m phases. Fig. 9 exemplifies, for a three-phase circuit, how these currents are combined. Let I' be the amplitude of the magnetising current, and the current of phase I. be equal to I'; in phases II. and III. it will become $\frac{I'}{2}$. As II. and III. are 120deg. apart, their resultant effect is again $\frac{I'}{2}$, which again acts in the direction I. The total magnetising current will hence be $I' + \frac{I'}{2} = \frac{3}{2}I'$—that is, it will be equal to that of a current $\frac{3}{2}I'$, which is supposed to flow in one phase winding.

The same result has analytically been deduced by E. Arnold; he found, in general, for m phases the equivalent current of one phase equal $\frac{m}{2} \cdot I'$ . . . . . (19)

Digitized by Google

The *magnetising force* of this current would be

$$\frac{4\pi}{10} \cdot w \cdot \frac{m}{2} I', \quad \ldots \quad (20)$$

and if ρ_H is the magnetic resistance of the main field per pair of poles, there results

$$H = \frac{4\pi}{10} \cdot \frac{w \frac{m}{2} I'}{\rho_H} \quad \ldots$$

If we substitute the effective primary current I_1 for the amplitudes I_1' and I', and remember that $I_1' = I_1\sqrt{2}$, we obtain from (12)

$$h_1 = \frac{4\pi}{10} \frac{w \cdot I_1\sqrt{2}}{\rho_{h_1}}, \quad \ldots \quad (22)$$

$$H = \frac{4\pi}{10} \frac{\frac{m}{2} I_1\sqrt{2}\sqrt{\frac{1-f}{1+f}}}{\rho_H}. \quad \ldots \quad (23)$$

I_1 can easily be calculated from the power, the losses, the primary tension, and the power factor f. Thus we can also determine

$$I_1' = I_1\sqrt{2},$$

and

$$\frac{m}{2} I' = \frac{m}{2} I_1\sqrt{2}\sqrt{\frac{1-f}{1+f}}.$$

By dividing equation (18) by (21)

$$\frac{h_1}{H} = \frac{\rho_H}{\rho_{h_1} \cdot \frac{m}{2}} \cdot \frac{I_1'}{I'} = \frac{\rho_H}{\rho_{h_1} \frac{m}{2}} \cdot \frac{I_1}{I}.$$

Further, (3A),

$$\frac{h_1}{H} = \tau \frac{I_1}{I},$$

and (11) and (11A)

$$\frac{\rho_H}{\rho_{h_1}} = \tau \cdot \frac{m}{2} = \frac{m}{2}\left(-1 + \sqrt{\frac{1+f}{2f}}\right) \equiv \frac{1-f}{4f} \cdot \frac{m}{2}; \quad (24)$$

and (17),

$$\frac{\rho_H}{\rho_{h_1}'} = \frac{z}{4m} \cdot \tau \cdot \frac{m}{2} = \frac{z}{8}\left(-1 + \sqrt{\frac{1+f}{2f}}\right) = \frac{z}{8} \cdot \frac{1-f}{4f} = \frac{z}{32} \cdot \frac{1-f}{f}$$

$$\frac{\rho_H}{\rho_{h_1}'} = \frac{z}{32} \cdot \frac{1-f}{f}. \quad \ldots \quad (25)$$

ρ_H and ρ_{h_1}' do not depend upon the dimensions of the iron masses alone. They are functions of the dimensions of the

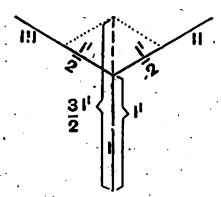

FIG. 9.

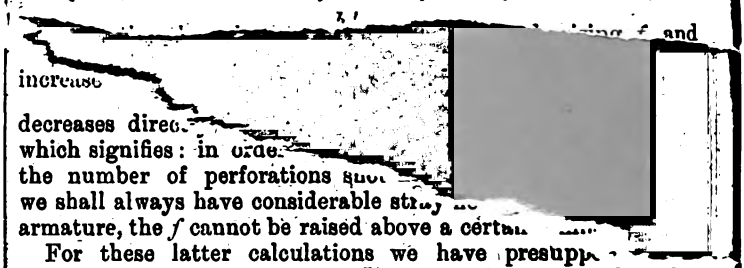
iron and of the air, and of the degree of saturation of the separate fields. The latter factor, the saturation, enters particularly when we have to ascertain the resistance ρ_{h_1}' of the iron-bound stray field in perforated armatures. For such armatures the fields have separately to be determined from the magnetising forces and the dimensions. The main field H must have a certain magnitude, which, as will be explained, depends upon the number of poles, of turns, and of alternations.

From H, the magnetising force, (23),

$$\frac{4\pi}{10} w \cdot \frac{m}{2} I' = \frac{4\pi}{10} w \cdot \frac{m}{2} I_1\sqrt{2}\sqrt{\frac{1-f}{1+f}},$$

and from the admissible density of the lines of force we derive the dimensions of the iron and air for the main field H. The number of perforations, their iron dimensions, and particularly the size of the iron bridge bars which remain on the surface of the armature, can be settled in the following way:—The magnetising forces, (14), $\frac{4\pi}{10} \cdot \frac{w \cdot 2m}{z} \cdot I_1'$ $= \frac{4\pi}{10} \cdot \frac{w \cdot 2m}{z} I_1\sqrt{2}$ produce, per perforation, stray fields h_1', such that, (15) and (16), $h_1' = \frac{h_1}{2}$, in which, (3A), $\frac{h_1}{H} = \tau \frac{I_1}{I}$, and therefore, (11A), (12),

$$\frac{h_1'}{H} = \frac{\tau}{2} \cdot \frac{I_1}{I} = \frac{1-f}{8f}\sqrt{\frac{1+f}{1-f}} = \frac{\sqrt{1-f^2}}{8f} \quad \ldots \quad (26)$$



increase

decreases direc-

which signifies: in orde-

the number of perforations

we shall always have considerable stra-

armature, the f cannot be raised above a certa-

For these latter calculations we have presupp-

$\tau_1 = \tau_2 = \tau$. This hypothesis will in general correspond to the actual conditions, for the two armatures will mostly be of the same type, either both grooved or both perforated. If the construction should be different, τ_1 and τ_2 may separately be deduced from equation (7); for τ we substitute the arithmetical mean $\frac{\tau_1+\tau_2}{2}$.

The grooved armature is easier to deal with than the perforated armature. The iron bridge bar which we notice in Figs. 8A and 8B on the surface of the perforated armature is here replaced by the air space t, Fig. 8C; the saturation of that thin piece of iron does not complicate our calculation.

The resistance of the stray fields is rather chiefly determined by the resistance of the air space of the stray lines of force, and is therefore constant for various loads.

The advantages of this are that with grooved armatures τ remains nearly constant with varying loads, but, above all, that it is much smaller than with perforated armatures.

When the ratio of the dimensions of the teeth and the number of teeth have been ascertained for a certain f, the other dimensions can be found by proceeding as in the case of a transformer.

(4) *Calculation of the motor for normal load.*—Given the work to be done L, the power factor f, and the losses for normal load—namely, electrical waste in the primary coils da_1, electrical waste in the secondary coils da_2, hysteresis and Foucault currents $da_{(H,F)}$, losses through friction da_r. The energy primarily to be supplied is

$$A_1 = L + da_1 + da_2 + da_{(H,F)} + da_r.$$

Each of the phases claims $\frac{A_1}{m}$, which is equal to $K \cdot I_1 f$. The current expended per phase is

$$I_1 = \frac{\frac{A_1}{m}}{K \cdot f}. \quad \ldots \quad (29)$$

The amplitude of the primary current is, per phase,

$$I_1' = I_1\sqrt{2}.$$

The magnetising current, (12):

$$I = I_1\sqrt{\frac{1-f}{1+f}},$$

and its amplitude: $I' = I\sqrt{2}$.

The magnetising force of the m phases, (19): $\frac{m}{2} I'$, the current supposed to be flowing in one phase winding.

The number P of pairs of poles follows from the speed:

$$P = \frac{\text{number of periods}}{\text{number of revolutions}}$$

The calculation can be finished as when dealing with a transformer, if we remember:

The magetising force in the main field H is, (20),

$$\frac{4\pi}{10} w \cdot \frac{m}{2} I',$$

Digitized by Google

The magnetising force in the stray field is, (18),

$$\frac{4\pi}{10} w\, I'.$$

The resistances opposed by iron and air are to be chosen such that the E.M.F. induced by H per pair of poles, $\frac{E}{P}$ becomes equal to $\frac{K}{P}$, *i.e*,

$$\frac{K}{P} = 10^{-8} \pi n w H,$$

$$\frac{\text{primary current } I_1}{\text{magnetising current } I} = \sqrt{\frac{1+f}{1-f}} \quad . \quad . \quad . \quad . \quad . \quad (12)$$

Further,

$$\frac{C'' C}{A C} = \frac{\cos(\phi_{min})}{\sin \frac{\phi_{min}}{2}} = \frac{\cos(\phi_{min})}{\sqrt{\frac{1-f^2}{8f}}}. \quad . \quad . \quad . \quad (30)$$

that is

The following equations summarise the calculations for a long, with furnace tubes 3ft. 3¾in. diameter. The heating surface is 2,287½ sq. ft., and the grate area 39 sq. ft. The steam was used exclusively for a simple Corliss condensing engine, with cylinder 28in. diameter and 4½ft. stroke, running at 60 revolutions per minute, driving the machinery in a wool-combing mill. The work was arranged so that it should be as nearly as possible equal on the occasion of each test. Owing to an oversight during the test made before the superheater was fixed, the feed was left on while the boilers were being cleaned, the usual custom being to raise the level before cleaning, and then stop the pump. The result was a fall in the steam pressure from 78lb. to 42½lb. per square inch, and the boiler was so fully loaded that it took two hours to recover the normal pressure. The speed of the engine fell to 58 revolutions per minute, although the trips on the Corliss gear ceased to act, and full steam was being taken for nearly an hour; 59 revolutions per minute were made for a further half-hour, before the usual speed was re-established. During the second test the same procedure was intentionally repeated, in order that both tests might be exactly compared; the result was that the steam pressure fell only 3½lb., and the speed was not affected at all. This difference is most striking, and is a forcible proof of the great increase in the capacity of a boiler when fitted with the superheating apparatus. The superheat was measured at the boiler stop-valve, and was almost constant at 56°F.

At Messrs. Henry Bruce and Son's, Kinleith Mills, Currie, Midlothian, five Lancashire boilers are fitted with McPhail's apparatus. Their principal dimensions are 28ft. long by 7½ft. diameter; heating surface 920 sq. ft., grate area 36 sq. ft., working pressure

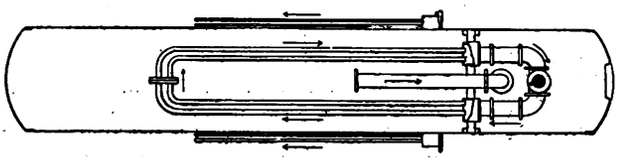


Fig. 6.—McPhail and Simpson Superheater.

about 90lb. absolute per square inch. In Table IV. is shown a test of the complete range of boilers, six without the superheaters against the five fitted with them.

At the works of the Thornliebank Company, Glasgow, a Lancashire boiler is fitted with McPhail's apparatus. Its dimensions

(I.) $$\frac{\rho_H}{\rho h_1'} = \frac{z}{3 2} \frac{1-f}{f}; \quad . \quad . \quad . \quad . \quad . \quad (25)$$

(II.) $$H = \frac{K\sqrt{2}}{10^{-8} \pi n s_1}; \quad . \quad . \quad . \quad . \quad . \quad (30)$$

(III.) $$\frac{2r}{\frac{z}{2} q l} + \frac{R_1}{\mu_1 F_1} + \frac{R_2}{\mu_2 F_2} = \frac{\frac{4\pi}{10} \frac{s_1}{P} \frac{m}{2} I'}{H}; \quad . \quad (20)$$

(IV.) $$I' = I_1 \sqrt{2} \sqrt{\frac{1-f}{1+f}}; \quad . \quad . \quad . \quad . \quad (12)$$

(V.) $$I_1 = \frac{\frac{A_1}{m}}{K \cdot f}, \quad . \quad . \quad . \quad . \quad . \quad (29)$$

s_1 being the total number of turns in one phase $= w P$;
F_1 the mean cross-section of the field in the primary armature;
R_1 the mean length of the field in the primary armature;
μ_1 the permeability of the primary armature;
F_2 the mean cross-section of the field in the secondary armature;
R_2 the mean length of the field in the secondary armature;
μ_2 the permeability of the secondary armature.

The dimensions of the iron masses, F_1, F_2, R_1, R_2, as well as μ_1 and μ_2, must be determined from the admissible losses $d a_{(H,F)}$. We bear in mind that the iron of the secondary armature may be strained to a higher degree, inasmuch as it is exposed to a lesser number of alternations. The number of turns and the current density follow from $d a_1$ and $d a_2$, as in the case of transformers. The ratio of transformation, and the number of phases in the secondary armature may be left to discretion; the conditions will not change in the coils of the short-circuit armature, so long as the *mass of copper* is not changed. The value of the secondary losses determines also the loss in speed or the slip of the motor. We shall demonstrate that slip $= \frac{d a_2}{A_1 - d a_1}$.

(To be continued.)

NOTES ON STEAM SUPERHEATING.*

BY WILLIAM H. PATCHELL.

(Concluded from page 545.)

In its complete form this superheater has been tested and fully reported upon by several engineers in this country, among whom may be mentioned Messrs. Crosland and Michael Longridge. In Tables III. and V. are given the results of some recent tests, one made by M. Armengaud at the works of Messrs. Isaac Holden and Son, Reims, and others at Kinleith and Thornliebank, for which the author is indebted to the manufacturers.

The Reims tests, Table III., were made before and after the apparatus was fixed on a Lancashire boiler 8½ft. diameter and 28ft.

* Paper read before the Institution of Mechanical Engineers.

Lancashire boilers, Nos. 6 and 7, each 28ft. long and 8ft. diameter; heating surface 955 sq. ft, grate area 39 sq. ft. Quality of fuel, Greenfield virgin coal. No. 7 boiler had superheater attached.

No. 7 boiler with superheater did 12·97 per cent. more work, or, in other words, the saving effected was 19·08 per cent. Lowry, being the regular fireman and acquainted with the boilers, obtained the best results.

are 28ft. long and 8ft. diameter; heating surface 955 sq. ft., grate area 39 sq. ft. One of their other boilers was tested against that fitted with the superheater, as shown in Table V. The superheat of the steam leaving the stop-valve of the boiler fitted with the superheater averaged 56·2°F. Since these tests a second boiler has been fitted with the same apparatus, producing steam at 80lb. per square inch above atmosphere and at 558°F., being a superheat of 234°F.

This type of superheater was adopted by the author in 1893 at the Maiden-lane station of the Charing Cross and Strand Electricity Supply Corporation, but had to be considerably modified to suit the Babcock and Wilcox water-tube boiler, as it was found possible to put only one set of superheating tubes in the limited space between the top of the water tubes and the underside of the drum, and only one set of radiating pipes in the drum: so that the arrangement represents only one-half of the complete apparatus as applied to a Lancashire or double-flued boiler. The arrangement is shown in Figs. 6 and 7. The saturated steam is taken from the anti-priming pipe to the upper box of the superheater, whence it passes down through the superheating tubes to the lower box, thence up into the radiating

Digitized by Google

pipes in the drum, and through these to the steam stop-valve. The principal dimensions of the Babcock and Wilcox boiler are :—9×9=81 tubes, 18ft. long and 4in. diameter ; total heating surface about 1,827 sq. ft. ; drum 23½ft. long and 4ft. diameter ; width of fire grate 5ft. 6in. ; total grate surface 34·4 sq. ft. The principal dimensions of the superheater are :—75 superheating tubes of 1in. diameter, heating surface 355 sq. ft. ; 12 radiating pipes of 2in. diameter, heating surface 174 sq. ft. ; area through superheating tubes 58 9 sq. in., through radiating pipes 37 7 sq. in., and through steam stop-valve 28·27 sq. in.

Complete tests of one boiler were made by Prof. Kennedy, before and after the superheating apparatus was fixed ; and the principal results are given in Table VI. The dynamos are Edison-Hopkinson continuous-current shunt-wound, driven by Willans engines :

The great increase in the capacity of the boiler will be noted in line 8 ; the steaming was much easier and steadier, and at the same time the efficiency of the boiler improved from 68·4 per cent. to 74·9 per cent. (line 29), and this with cold feed. Practically the whole of the superheat was lost in the range of steam pipes between the boiler and engine. The slight difference in water used per kilowatt-hour may be accounted for by the engine not being in such good order in the second test as in the first. It had been thoroughly overhauled immediately before the June trial, and had been in daily use from that date until the October trial, so that both valve and piston rings would be somewhat slacker in October than in June. The same cause would affect the coal consumption, which nevertheless shows a saving of 13·5 per cent.

The increased capacity and ease in working of the boiler have been as marked in its subsequent use with the superheating apparatus ; in regular work it is evaporating about 50 per cent. more than heretofore. At first the author had some misgivings as to incrustation forming in the superheating tubes from the priming water ; but from examining them closely on several occasions after a run of 4,000 hours and more, and finding them perfectly clean, he is satisfied on this point. The top box, by its increase in area over the steam pipe, gives a period of comparative rest in the flow of the steam, and acts as an efficient separator for the water or scum carried over. A steam trap fitted to the box discharges any such accumulation regularly, thus preventing its being carried into the superheating tubes. The bottom box is also fitted with a trap to intercept any leakage from the steam stop-valve when the boiler is shut in.

The first apparatus proved so satisfactory that a second was applied to the companion boiler in 1894, when the effect of the superheated steam in the pipes began to be marked by a decrease in the discharge from the drains and in the leakage from joints. There are altogether seven boilers, of which five or six are in general use on a common steam main. The figures in Table VII. show this effect clearly.

Induced Draught.—The duty of the boilers having been increased to the above extent, and the priming difficulty being quite overcome,

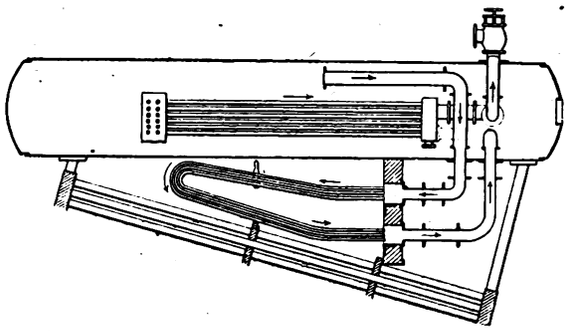

FIG. 7.—McPhail and Simpson Superheater.

the only limit to the evaporation was the chimney draught. As the two boilers were fitted with an independent flue and chimney, they lent themselves readily to an experiment in this direction. Having considered several schemes of forced and induced draught as an auxiliary, the author finally decided on putting the fan in the flue at the back of the boilers. As there was no space available for any

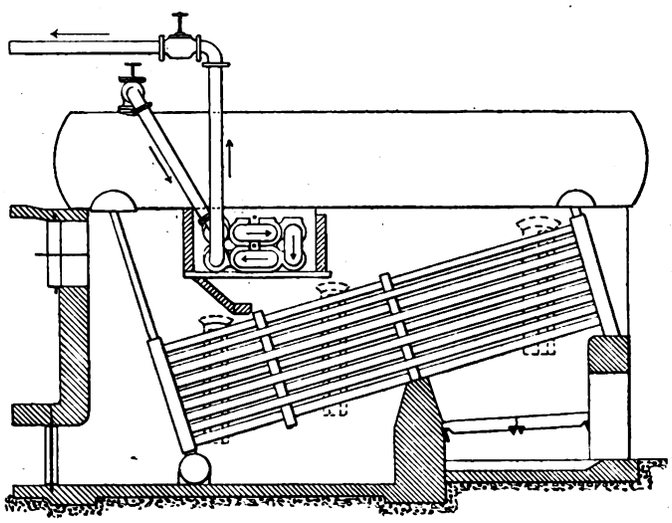

FIG. 8.—Schwoerer Superheater

form of economiser between the boilers and the fan, no attempt could be made to diminish the loss from heat in the waste gases. The gain sought for was in the direction of increasing the capacity of the existing boilers, so as to render steaming independent of the natural effects of foggy or heavy weather, and by working the boilers at a higher rate to diminish the proportion of radiation losses, which are practically constant at all loads.

The fan selected is a 72in. single inlet, made by Messrs. G. E. Belliss and Co., and driven direct by one of their tandem compound self-lubricating engines, having cylinders 3½in. and 6in. diameter, and 4½in. stroke, working at 150lb. boiler pressure and running at 300 revolutions per minute. The engine and fan were put in somewhat large for the estimated work, in order to secure slow speed and quiet running, with the result that within a few feet of the fan it is impossible to tell by the sound whether it is running or not ; this is a marked improvement on many fan engines. A draught in

Digitized by Google

the flue at the fan inlet equal to a 2in. water gauge has been easily maintained. The usual method of working is to work the boilers on natural draught at times of light load, and then, as the load increases, to start the fan, close the by-pass in the flue, and work steadily at 1in. water gauge. With this draught the superheater tubes are continually bathed in incandescent gases, but not the slightest trouble has been experienced with them. In order to test the thorough reliability of the tubes, and in view of the fact that trouble was most likely to arise, if at all, when getting up steam, one of the boilers was shut in, and the steam let down day after day for some weeks, and then raised again with the induced draught, and there was an entire absence of any signs of irregularity or trouble.

When the boiler is steaming freely an iron bar inserted through the brickwork to a point near the ends of the tubes soon becomes red hot, and the temperature as taken by a platinum coil pyrometer at this point is about 900°F. At this temperature it appears to be of little importance whether the cooling agent is water or steam, so long as the circulation is kept up. This circumstance is most interesting in view of Mr. Durston's Devonport experiments, reported in his presidential address to the Institute of Marine Engineers,* as to the permissible limit of temperature in a tube or tube plate, which he places at about 750°F.; and in view also of the grave doubts that are frequently expressed as to the safety of steel tubes exposed to furnace temperatures without a perfect circulation of water on the other side of the metal. What temperature the tubes actually reach the author is unable to state; but the steam coming out of them is over 600°F. The tube plates would be lower in temperature than the outer ends of the tubes, because the gases are drawn downwards and away from the plates by the draught. No trace of leakage at any one of the tube ends yet appeared.

A further test of the boiler with the induced draught was made on January 2, 1896. It was not possible to shut off part of the steam ring main, and to use the steam on certain steam dynamos only, measuring the electrical output from them, as had been done in the two former tests; an evaporative test only was therefore arranged for. The stop-valve temperature was measured about 5ft. from the stop-valve at the boiler, on a branch pipe about 10ft. long, connecting the boiler with the main ring. A mercury thermometer in a mercury cup let into the steam pipe was used in this position. Being anxious to get the temperature of the steam between the superheater and the radiating pipes in the drum, the author had tried mercury thermometers, which failed. The difficulties due to the high pressure and temperature were successfully overcome, however, by Mr. F. W. Burstall, to whose ingenuity and kindness in co-operation the author is indebted in this matter. With a temperature of 1,058deg. around the superheating tubes, steam entering at 362deg. left them at 650deg., and after passing through the radiating pipes in the drum left the boiler at 403°F. The principal results are given in Table VIII., the boiler being fired with Welsh steam coal. It will be noted that the application of the superheater, together with a stronger draught, has increased the capacity of the boiler by 140 per cent., or raised the evaporation from 3,457lb. per hour (Table VI.) to 8,293lb. without increasing the space occupied: which is a most important gain, and a saving both in capital and in rent. In comparing the temperature here given of the gases leaving the boiler with those given in Table VI., it should be noted that in Table VIII. the temperatures were taken between the back tubes and the wall in which is situated the damper communicating with the flue. In Table VI. the temperatures were taken in the flue, where the gases are cooled by the influx of cold air through the damper slots, and by any leakage through the other boiler, which was shut off at the time.

* *Engineering*, October 4, 1895, p. 437.

Schwoerer's Superheater.—The superheater illustrated in Figs. 8 to 10 is the invention of Mr. Emile Schwoerer, of Colmar, Alsace, who was for some time private secretary to the late Mr. G. A. Hirn. It was Mr. Hirn who first took up superheating seriously; and it is due to his energy that so much has been done with it in practical working in Alsace. Mr. Schwoerer's improvements were in the direction of reducing the space occupied by the apparatus; and he attained this end by employing a coil of pipes with gills on them both inside and outside, thus getting large surfaces in a small bulk. Regulation of the superheat by deflecting the hot gases away from the tubes, rather

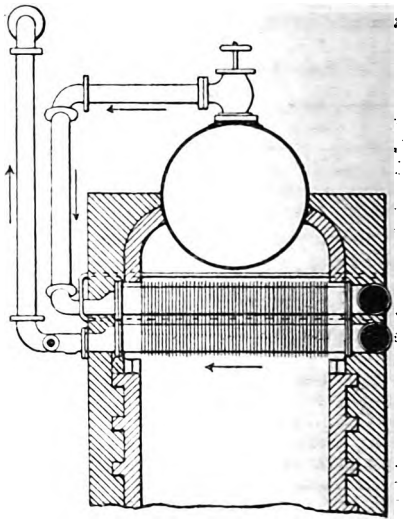

Fig. 9.—Schwoerer Superheater.

than by varying the proportion of the total steam passing through the tubes, is due to Mr. Schwoerer, though this regulation does not appear to have been generally carried out. By the courtesy of Prof. W. Cawthorne Unwin the author is enabled to give the tests in Table IX. of Schwoerer superheaters in Alsace, some of which were carried out by himself and others by Mr. Walther Meunier, Engineer-in-Chief of the Alsatian Association of Steam Users. It will be noted that in tests 1, 3, 5, 9, one more boiler was required to do the work when saturated steam was being used at the engine. The boilers were of the elephant kind, with Green's economisers.

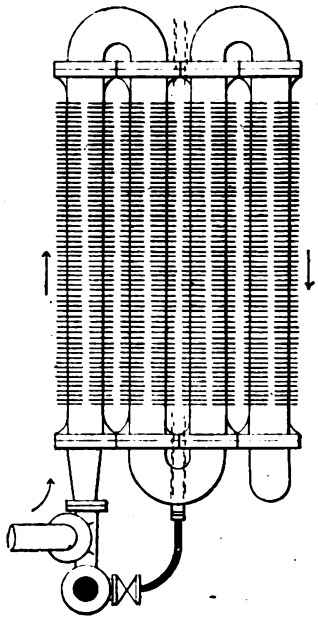

Fig. 10.—Schwoerer Superheater.

An application of the Schwoerer superheater has been made by Messrs. James Simpson and Co. to a Babcock and Wilcox water-tube boiler at the Grand Junction Waterworks, Kew.* The arrangement is shown in Figs. 8 to 10. The boiler is of the same size as those fitted by the author with McPhail's apparatus at Maiden Lane. Full details of the trials unfortunately cannot be obtained; but the saving effected is satisfactory. Tests were conducted by Mr. Osbert

Chadwick before and after the superheater was fixed, with the following results (Table X.):—

Table X.—*Boiler Tests Without and With Schwoerer's Superheater.*

Date	Jan. 21, '93.	Dec. 20, '93.	Feb. 22, '94.	Mar. 13, '94.
Degree of superheat, Fahr.	0°	57·7°	109·5°	57·0°
Steam per pump, H.P. per hour ..... lb.	20·98	19·71	18·75	19·48
Saving effected...per cent.	...	6·05	10·63	6·75

A test was also conducted by Mr. Goodman, the Superintending Engineer at the pumping station, under ordinary working conditions from December 8, 1894, to January 5, 1895, the engine and boiler being kept continually at work. The fuel used was 86·98 per cent. anthracite peas and 13·02 per cent. breeze, the draught being assisted by a Meldrum blower. The results then obtained were:—

Duration of trial	723½ hours.
Feed water per hour	3223lb.
Fuel per hour	471lb.
Steam per pump horse-power per hour	17·74lb.
Fuel „ „ „	2·58lb.
Mean superheat	121°Fahr.

These results showed a saving of about 15 per cent. on what had been obtained before the Schwoerer superheater was fixed.

This type of superheater is also made by Messrs. Fraser and Chalmers, Erith, who have one in constant use at their works.

Sinclair's Superheater.—Another form of superheater is shown in Fig. 11, which is due to Mr. George Sinclair, of Leith. There is

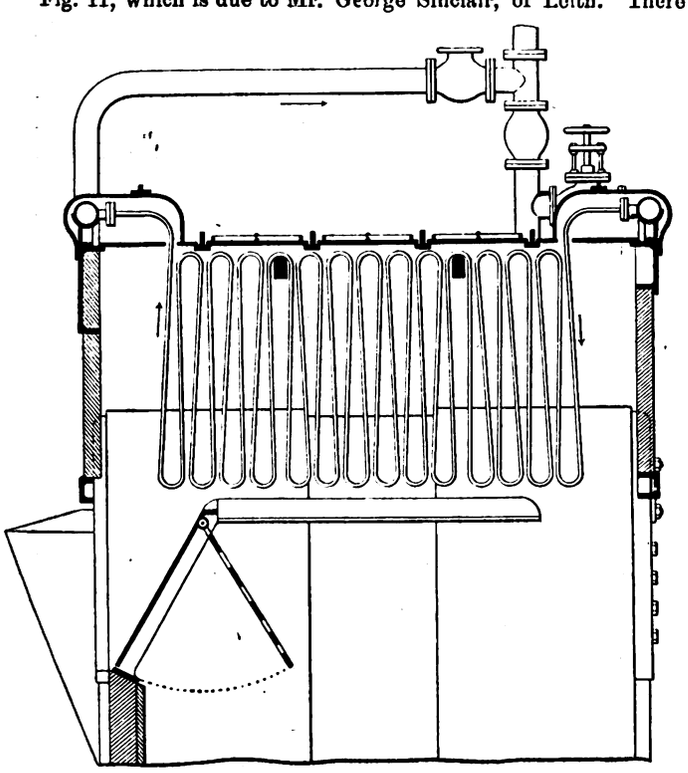

Fig. 11.—Sinclair Superheater.

here a departure from the usual method of securing the tubes, which in this apparatus are flanged and bolted to the cross inlet and outlet pipes, instead of being expanded into them. In such positions an expanded joint is generally considered desirable; but here the joints are removed from the action of the hot gases, and a bolted joint gives much greater facilities for removing a tube in order to examine or clean it. In Fig. 11 the apparatus is shown in conjunction with a marine dry-back boiler, as fitted by Prof. Kennedy at the Edinburgh Electric Lighting Station. The arrangement is very compact, and should prove highly economical. The hot gases from the smoke box at the front are led to the back over the top of the boiler, passing among the superheating tubes; thence down the sides of the boiler to the centre flue underneath it. The apparatus was described in Mr. Burstall's Paper read at the last meeting (October, 1895).

It is much to be regretted that so little has been done as yet with superheated steam at the engine. In nearly every instance the superheat appears to be gone, if not at the steam chest, at any rate immediately on admission to the cylinder. But even under these circumstances the advantage of superheating is manifest from many of the tests given above; and it must be recognised that, although the steam may be cooled down again to the temperature corresponding with the pressure, it is still dry steam, and is a better working gas than the saturated solution of water dust supplied by an ordinary boiler. The desirable amount of superheat has been generally considered to be the equivalent of the heat lost by initial condensation; but this does not obtain in practice. The amount of heat lost in initial condensation is generally from 20 to 25 per cent. of the total heat of the steam above boiling point. Tests with superheated steam show a saving of 20 per cent. with only 5 per cent. extra heat in the steam. This point has been brought out clearly by Mr. W. H. Booth in his Paper on cylinder condensation, read to the Manchester Association of Engineers a few months ago, wherein it was shown that the amount of superheat is but little in excess of that necessary to supply the heat required for making good the latent heat which disappears as work during expansion.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-day) FRIDAY, February 28th.

PHYSICAL SOCIETY.

5 p.m. Meeting at Burlington House. Papers to be read: (1) "Experiments with Incandescent Lamps," by Sir D. Salomons. (2) "On the Alternating Current Arc," by Dr. Fleming and Mr. Petavel.

ELECTRO-HARMONIC SOCIETY.

8 p.m. Concert (Ladies' Night) at the St. James's Hall Restaurant.

SATURDAY, February 29th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "Light," by the Right Hon. Lord Rayleigh, F.R.S.

MONDAY, March 2nd.

SOCIETY OF ENGINEERS.

7:30 p.m. Ordinary Meeting at the Royal United Service Institution, Whitehall. Paper to be read: "The Mechanics of Horse Haulage," by T. H. Brigg.

CHEMICAL SOCIETY.

8 p.m. Meeting at Burlington House.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture III.: "The Chemistry of Certain Metals and their Compounds used in Building, and the Changes produced in them by Air, Moisture, and Noxious Gases, &c.," by Prof. J. M. Thomson.

TUESDAY, March 3rd.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be read: "On Littoral Drift in Relation to River Outfalls and to Harbour Entrances," by W. H. Wheeler. At this meeting the monthly ballot for members will be taken.

WEDNESDAY, March 4th.

INSTITUTION OF ELECTRICAL ENGINEERS.

6 p.m. Students' visit to the Central Stations of the St. Pancras Vestry. Meeting at Stanhope-street Central Station, near Gower-street or Portland-road Stations.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Paper to be read: "Röntgen's Photography of the Invisible," by A. A. C. Swinton.

The Electrician.

The Oldest Electrical Journal (1861—1878.)

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny
Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON,

Telephone No. 6949. *Telegrams:* "ELECTRICIAN NEWSPAPER LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed "Coutts and Co."*

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The Rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	Year.	Half-Year.	Quarter.
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.

(Post free, payable in advance.)

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 4 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. FLEMING, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Vol. I. Price 12s. 6d., post free 13s. *Vol. II. is in preparation.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.
VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free, 8s.
VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. 93 original illustrations, handsomely bound. price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. SNELL. 10s. 6d.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free 8s.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d. net, post free, 13s., abroad, 13s. 6d.

"THE ELECTRICIAN" PRIMERS. In Two Volumes. Price: Stout paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

THE WORK OF HERTZ. By Dr. O. J. LODGE. Price 2s. 6d.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 8s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*In preparation.*

MOTIVE POWER AND GEARING. By E. TREMLETT CARTER. [*In preparation.*

FULL CATALOGUE POST FREE ON APPLICATION

CONTENTS OF THE CURRENT NUMBER.

NOTES	573
Electromagnetic Theory. By O. Heaviside. Cont. Illus.	576
Theory and Calculation of Asynchronous Alternate Current Motors. By A. Heyland. Continued. Illustrated	578
Note on Steam Superheating. By W. H. Patchell. Illus....	581
THE PROLONGATION OF PATENTS.	586
Reviews.....	587
Electric Traction by Polyphase Currents	589
The Lessing Dry Cell	589
Dielectric Strength of Oils under Alternating Potentials. By Prof. Elihu Thomson.....	591
The Electric Railway System of Montreal, Canada	592
On the Generation of Longitudinal Waves in Ether. By Lord Kelvin, F.R.S. Illus.	593
Physical Society	593
CORRESPONDENCE—	
The Electrical Engineer and Military Service.—W. H. Pretty	594
CORRESPONDENCE—*continued.*	
The Discovery of the Electric Arc.—A. Smirnoff	594
Legal Intelligence	595
Trade Notes and Notices.....	596
COMPANIES' MEETINGS AND REPORTS—	
City of London Electric Lighting Company (Ltd.)	601
Notting Hill Electric Lighting Company, Limited	603
Charing Cross and Strand Electricity Supply Corporation (Limited)	604
Central London Railway Company	605
Chelsea Electricity Supply Company (Limited).....	606
Telegraph Construction and Maintenance Co. (Limited).	606
Isle of Man Electric Tramways and Power Co., Ltd.	607
Liverpool Electric Supply Company (Limited).....	607
Scarborough Electric Supply Company (Limited).....	607
Companies' Share List	608

NOW READY.—Vol. XXXV. of "THE ELECTRICIAN," bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

The published price of Volumes previous to Vol. XXXV. is 12s. 6d. post free 13s. 6d. Many of these Volumes are very scarce.

THE PROLONGATION OF PATENTS.

An invention is at the best somewhat of a speculation. As hardened inventors know full well, it is not enough to be inspired with a good idea and to be possessed of a patent purporting to cover it. A "good" patent is worth more than a good idea, and plenty of capital is better than either. The gentle system of trial by fire must have yielded some curious results in its day, but as a device for awarding approximate justice we are not at all disposed to admit that it was decisively inferior to the ordeal to which we subject a patentee in this year of grace. No doubt if Dr. JOHN HOPKINSON, on the morning of Wednesday, November 2, 1892, when the action of "Hopkinson *v.* the St. James' and Pall Mall Electric Lighting Company (Limited)" came on for hearing before Mr. Justice ROMER, had been given the choice of walking blindfolded and barefooted over 9ft. of ploughshares warmed to the equable temperature of, say, 800°C., or of undergoing the more modern substitute for this painful process, he would have availed himself of the latter alternative with alacrity. Possibly, however, if comparative statistics were available, it would be found that the chance of a miscarriage of justice by the ploughshare test was not appreciably greater, and the method was certainly shorter and less of an elaborate and expensive deception. The element of luck entering, therefore, to such an extent into the business of inventing and patenting, it would seem desirable not to add to it unnecessarily. But this, to our mind, is precisely the tendency of the present system of extending the term of a patent when it can be proved to the satisfaction of the Judicial Committee of the Privy Council that a patentee or his assignee has been inadequately remunerated. If careful inquiry were to show that as a rule it was not possible for patentees to reap their due reward in 14 years, that would be a reason for extending the term of *all* patents. As it is, an industry

Digitized by Google

frequently acquiesces in the payment of tribute to the owners of a patent, not because it is regarded as a good one, legally or ethically, but because it has only a few more years to run. Then, just as the moment of expiry arrives, the royalty receivers announce their intention of applying for a prolongation, and the whole basis upon which a peaceful submission to their claims was made is swept away. It is true that in most instances the life of a patent is not prolonged for many years, and that its prolongation is often accompanied by conditions tending to mitigate any hardship inflicted on an industry, but it may be extended by another seven years, and in exceptional cases by another 14 years. Hence not only is it a chance whether or no a patent will be kept alive beyond its normal age, but the amount of the added increment is also problematical. Surely this is an altogether unnecessary and undesirable addition to the notorious uncertainty of patent law—some of which is, of course, inherent to all mundane transactions, but most of which is merely due to the intricate, illogical and inchoate state of the law, a condition easily remediable by a broad-minded public-spirited lawyer, endowed with a strong will and given a free hand. The more the element of pure chance is imported into any class of transaction the more do these transactions tend to degenerate into a mere gamble—an exciting pursuit we doubt not, but never encouraged with impunity by the State. As matters stand at present a patentee neither knows, nor, humanly speaking, can know, whether he has been genuinely anticipated; whether, notwithstanding the care taken by his legal adviser in drawing up the specification, the impish ingenuity of another gentleman of the robe may not discover a fatal technical flaw or unearth from Limbo a plausible "prior user." And to legal difficulties are superadded doubts as to whether a public want is filled by the invention and as to whether the idea will commend itself to the omnipotent but not omniscient capitalist. Finally, to make sure that the venture shall lack every single element of certitude, the term of a patent, if the patent should, by a rare concatenation of favourable circumstances, survive the many "ifs" and "ands" that beset its path, is not a fixed invariable quantity, as it might well be, but anything from 14 to 28 years.

The patent system, notwithstanding all its defects, artificial and natural, is incomparably superior to the secrecy of trade guilds and the like, and the fundamental idea underlying it is an exceedingly obvious one. In return for a full disclosure of a method or process, the public grants a legal monopoly of it to the individual for a limited term. The nation's fund of technical knowledge is thereby increased, and technical progress is stimulated. If the monopoly grant too often proves a snare and a delusion, or if its term is too short, the inventive minds of the nation will assuredly revert to the baneful secrecy of ancient times; baneful to the inventor, because it is not in the long run as profitable by reason of the expense and trouble entailed by maintenance of secrecy; baneful to the nation, because trade secrets are very liable to become extinct, and close-rings do not tend to improvements in methods. On the other hand, the public is a loser if the term of these legal monopolies be unduly prolonged, or if patentees be allowed to evade a full disclosure. The main advantage that accrues to the patentee under the patent system is, or should be, certitude. How far this great desideratum is attained, when even the duration of a patent is a matter of judicial caprice, we leave our readers to judge.

But, taking things as they are, and not as they ought to be, what chance of prolongation into the twentieth century, may we ask, has the famous three-wire patent, No. 3,576, of July, 1882? The only ground upon which the term of a patent may be extended is the inadequate remuneration of the patentee or his assignee; and a case of inadequate return having been made out, the patentee then has to show that his invention is of unusual merit, and that it is through no fault of his own that he has not made enough money out of it. In 1892 the Westinghouse Company endeavoured to use the three-wire patent as a means of extracting royalties from the St. James' and Pall Mall Company; a lawsuit was the natural result. In November the case occupied the Courts for ten days, and on January 14, 1893, Mr. Justice Romer vindicated the aspersed validity of the patent. As no appeal was made, and as royalties were subsequently paid by the defeated parties and by others, we may assume that the patent is, legally speaking, a tolerably good one. So much for the validity of the patent. As to its intrinsic worth, no disinterested electrical engineer would, we think, venture to question its "unusual merit." Again, since it was impossible, owing to the practical non-existence of three-wire systems of distribution in England prior to 1890, to put the patent into force until more than half of its normal life had passed, and since Mr. Justice Romer's judgment was not actually delivered until the beginning of 1893, that is to say, until within 3½ years of the expiry of the patent, there can be no gainsaying the fact that the patentee or his assignee had but little time in which to reap a fair reward. However, if a field be fertile and the tiller industrious and acute, a large profit may be made in a short while. Has this been the case with Patent No. 3,576 of 1882? The levy of £2. 10s. per annum per ton of copper laid was certainly not extortionate, and municipalities and companies who have not seen their way to pay even this modest tribute do not appear to have been harried. In short, no burdensome or vexatious hindrance has been imposed upon the progress of the electric supply industry by the owners of the three-wire patent. Nevertheless, the aggregate tribute received will have to be disclosed to the last cent, and the Judicial Committee of the Privy Council may very well deem it adequate, especially if the municipalities show as much fight as they threaten to. On the whole, however, we should not be surprised if the three-wire patent were prolonged, and we do not see that its prolongation should give cause for serious regret.

REVIEWS.

The Electrical Transmission of Energy. By Arthur Vaughan Abbott. (New York: D. Van Nostrand Company. London: Sampson Low, Marston and Co.)

Lest readers of the above title should imagine that this book deals with a subject which already has been treated in many excellent works, we may at once add the sub-title, "A Manual for the Design of Electrical Circuits." And a most valuable manual it is, for large as is the amount of information on this subject scattered up and down among *Proceedings* and *Journals*, there is no work to compare with this in the thoroughness with which the subject is dealt with. The author states in his preface that the work has been prepared as "an endeavour to collect and arrange in an accessible form the data necessary for the scientific designing and proportioning of electric circuits, . . . a subject so aptly and untranslatably termed by the French *canalisation*." After an introduction on "Distribution" in its varied methods —series, parallel, mixed, and indirect—followed by a useful chapter on the mechanical and electrical properties of wire, we have valuable chapters on aerial lines for general work and electric railway circuits. Seeing that the author is an

Digitized by Google

American, and bearing in mind the general character of American overhead constructions, we can only say that after reading these chapters American constructors will sin wilfully, not of ignorance. To English engineers it is only necessary to call particular attention, as the author does, to the difference of climate in different countries as necessitating differences of material for insulators, and differences of treatment for timber and other constructional material. Then underground circuits, cables and conduit systems of all sorts are described and copiously illustrated with notes of their practical working. After a chapter on electrical measurement, the laws of continuous-current circuits and of alternating-current circuits are dealt with. Chapter VIII., on the latter subject, is probably the most lucid exposition of the method of calculating the constants for combined series and parallel resistances, inductances and capacities which has been put before students at any time. All these chapters, occupying half the book, bring the subject to the point of the actual design of conducting systems for any given conditions. Perhaps few scientific rules have had more laid upon them which they were not intended originally to carry than what has been named Sir William Thomson's law for economy in conductors. The fact is, this law only considers a conducting system from one point of view, and, as the writer of this book points out, there are at all events eight. In addition to the economic point of view, mechanical considerations, *possible* capital outlays on stations and generating plant, good and regular service to customers, maximum possible income with minimum outlay on station, are all points of great practical importance which Thomson's law does not, and was not intended to include. It cannot be overlooked that many electric undertakings never would have come into existence if the capital outlay demanded by Thomson's law had been adopted. These points the author deals with in detail, and as they involve questions of cost of conductors of various kinds, of machinery, of stations, of coal and water and of units and watts, all these items are illustrated by tables and diagrams of a very valuable nature. It is impossible within the scope of a short review to deal with a fraction of the contents of this book. In subject useful, in matter most painstaking and lucid, illustrated by 289 figures, each of which conveys what pages of words would not, with 74 tables embodying an enormous amount of information, with nine large folding plates for graphical solution of problems (these latter in a neat pocket, forming the back cover of the volume), it forms a book which completely covers this branch of engineering. And not the least valuable parts of its make up are the table with which it commences, giving the symbols used throughout and their meaning, so as to avoid endless repetition, (or what is worse, the use of the same symbol for different things in different parts of the book); and the copious index with which it ends, containing on an average about three references to each of the nearly 600 pages which it comprises.

Elementary Treatise on Electricity and Magnetism. Founded on Joubert's "Traité Elémentaire d'Electricité." By G. C. Foster, F.R.S., and E. Atkinson, Ph.D. (London: Longmans, Green and Co. 1896.)

The va'ue of any given educational work depends upon the time and place of its use. An otherwise excellent work may cease to possess any educational value whatever, and may be useful only to the antiquarian or the collector when translated from its native place or proper age into a foreign region or a later period of time. These trite reflections naturally suggest themselves when the idea of a translation into English of Joubert's "Traité Elémentaire d'Electricité" is proposed. For, though in the continental school of electricians of a few years ago such a work as the one by Joubert just named represented orthodox theories in clear and lucid language, the same work done into the language and used by the countrymen of Maxwell must conflict with views which have long taken firm root in the soil of English science. Doubtless considerations such as these influenced Profs. Foster and Atkinson in deciding to abandon the scheme of a simple translation of Joubert and to weave instead upon the skeleton of Jobert's treatise a modernised and Maxwellian presentment of the elements of electrical science. The result has been the work before us; and in it we find that but little that was Joubert's has remained, and much has been introduced by the adapters which is essentially based upon the hypothesis of action within a medium, as opposed to the notion of action at a distance, which latter view was adopted by Joubert. Thus, for example, the phenomena of electrostatics are considered in relation to the condition of the dielectric, and not as being inherently due to the charged conductors. In fairness to M. Joubert, however, we should say that he professed to attempt little more than a statement of the bare facts of electricity and magnetism, without reference to what, at the time and place of its writing, would have been regarded as debateable hypothesis; while his adapters have carried their work into a much more advanced and philosophic stage, having analysed the bases of the phenomena and sought to connect them upon the Maxwellian hypothesis. This extension of the scope has inevitably resulted in the introduction of a more mathematical treatment than that employed by Joubert.

While a considerable amount of technical matter is discussed, especially in the later chapters, this book appeals more to the student of theory than of practice. It is a book rather for the physicist than for the engineer. The interlinking chain of electrostatic and magnetic phenomena is entered at the same point as that selected by Maxwell—namely, at the time-honoured subject of "electrification by friction." The electrostatic is made the basis of the reader's ultimate conception of the interdependent phenomena of electricity and magnetism. This has been, with but one or two notable exceptions, the starting point for the theorist and the physical student, though, as has recently been pointed out by Dr. John Hopkinson, it is often to the advantage of the practical student to commence with the phenomena of the electric current. Yet, while ignoring the antiquated action-at-a-distance idea of electrostatics, the adapters have retained the system of units which has its sole basis in that obsolete conception. Not the Heaviside units, not any rational system of units, but the irrational—though unfortunately fashionable—C.G.S. units are used throughout this treatise. Surely a treatise which omits all reference to Heaviside from its pages, and all mention of the rational system from the chapter on "Units," cannot justly claim to be modernised, however Maxwellian it may be.

Regarded from the standpoint adopted by the writers, and upon the lines selected by them, this work is worthy of the serious attention of students of elementary electrical science. By its careful perusal they will obtain an accurate insight into the more important phenomena of the science, their logical connection and their bearing upon the principal branches of electrotechnics and electrical engineering. Its language is terse and clear; its mathematics are not beyond the stage at which everyone who seeks the end in view should have arrived; and its numerous illustrations are well executed and are to the purpose. It should prove a useful introductory to higher studies in electrical science.

Mesures Electriques. By Eric Gerard. (Paris: Gauthier-Villars et Fils.)

The measurement of electrical and other physical quantities with which the electrician and the electrical engineer are concerned forms the greater part of the curriculum of electrical laboratories, whether they are devoted to pure science or to technical applications. Indeed, one of the main points of difference between the college-trained worker and the so-called "practical man" is that the one knows more or less what is meant by accurate measurement, and understands how to get the best work out of his instruments, while the other uses them with a simple faith in the maker, and prefers direct methods and direct-reading scales.

Prof. Gerard's treatise on Electrical Measurements will be of considerable assistance not only to those engaged in teaching and their students, but also to the managers of testing and standardising departments in works and electric supply stations. In a large book of over 400 pages he gives descriptions and investigates the measurement of all quantities likely to be dealt with in an electrical laboratory. Commencing with an excellent chapter on the theory of measurements and errors, including some

Digitized by Google

good advice on the method of reporting results, he follows with an account of photometry and photometric instruments. About one-half of the book is devoted to measuring instruments, galvanometers, standard units and other apparatus, with methods of measurement of current, E.M.F., resistance, capacity, self and mutual induction, power, magnetic measurement of iron and terrestrial magnetism. Special applications, including the resistance insulation and capacity of telegraph and electric light systems and the determination of faults, the testing of primary and secondary batteries, and of continuous and alternating-current dynamos motors and transformers, occupy the rest of the book. At the end there are some useful tables of resistances of metals and liquids, with temperature corrections, and a brief set of instructions on the use of the slide rule.

Such a wide field obviously renders impossible an exhaustive treatment of each branch, and the book will not give much new information to an expert in his particular subject. Moreover, the proportion of space allotted to each part may not receive the approval of some specialists. In fact the discussion of dynamo, motor and transformer testing is perhaps the least valuable part of the book, being hardly more than a short *résumé* of some of the methods in vogue, and the descriptions are not sufficiently full to admit of this portion of the book being used by inexperienced workers. A similar paucity of information may be observed in the chapters on commercial measuring instruments and switches. The few that are mentioned are not altogether representative, and more information would be obtained by a student from a few makers' catalogues than from these chapters. The illustrations, in some instances, are merely pictures of the outside case of the instrument, and convey no useful information. In spite of these blemishes, the greater part of the book contains a large amount of well-arranged and useful information, with very few sins either of omission or commission. In the chapter on Photometry the Methven screen is not mentioned among the standards, perhaps with some justice. The multitudinous methods of measurement of resistance, capacity, E.M.F. and the like are carefully and clearly given, and a feature of the book is an investigation of the probable error in each case and the conditions of maximum accuracy. It is surprising that Carey Foster's adaptation of the Wheatstone's bridge is not mentioned in any of its forms, and there is apparently room for improvement in the potentiometer methods in vogue at Liège, since the arrangements described in the book are unnecessarily complex.

It is to be regretted that references to original Papers are not more frequent. If this had been conscientiously carried out, a short description would have amply sufficed to indicate the suitability of a method, but without such reference the student is put to very great trouble. Again, a criticism of alternative methods, and a few words as to the accuracy and limiting conditions of each, would from the hands of an expert be of extreme value. We note, for instance, that Frisch's method of determining faults in installations by means of a single voltmeter is given without a word of caution, whereas, as a matter of fact, it is useless unless there is only one fault, and the insulation of therest of the circuit is indefinitely high, conditions which are not likely to occur in practice.

Nevertheless, the book is well up to date, the language is simple and straightforward, the mathematics clear and free from unnecessary complications, and the diagrams are plentiful and admirably executed. In all electrical laboratories it deserves a place.

ELECTRIC TRACTION BY POLYPHASE CURRENTS.

What we believe to be the first application of polyphase currents directly to electric traction is now being made by Messrs. Brown, Boveri and Co., at Lugano, in Switzerland. At this place an electric railway is being equipped with polyphase plant, and will, it is hoped, shortly be ready to start work. Preliminary trials have already been made with successful results.

The power for this railway is derived from a waterfall, where a power house has been installed with a 300 H.P. turbine, driving two 150 H.P. three-phase alternators. The power is generated at 5,000 volts, and a portion of it is used by a chocolate factory near the power house. The three-phase generators are of a special type, in which the only moving parts are the iron star-shaped pole cores. Both the field coils and the armatures are stationary.

Three-phase current for the railway is conveyed at 5,000 volts, overhead, over a distance of 12 kilometres (7½ miles) to Lugano, where it is transformed down to 400 volts by ordinary transformers. The power is there distributed to the cars by means of two aerial or trolley lines, the third conductor being supplied by the rails. Three-phase motors on the cars receive power through a double trolley-wheel apparatus; and a special form of controller is used when varying the speed or reversing the car. The motors are designed to give a normal speed of 15 kilometres (9⅜ miles) per hour.

The advantages which attend the use of polyphase currents for electric traction are, principally, in enabling power to be derived from a distant source, and in allowing of the use of motors which require no commutator, collector, nor bare electrical conductor upon them. On the other hand, a double trolley line and the duplication of the trolley collector wheels are rendered necessary. Of the modifications in the controller which are involved, we cannot now speak particularly; though it seems probable that a more complicated construction than where the current is continuous would be essential, this need not, however, necessitate additional complexity in the manipulation of the controller. The use of two overhead conductors must also present a disadvantage, from the increased risk of breakdown due to a telegraph or telephone wire falling across them.

We are indebted to S. Giovanni Giorgi, of Rome, for the foregoing particulars of the Lugano electric railway, the further development of which will be watched with interest by electrical engineers.

THE LESSING DRY CELL.*

During the last few years the advantages of the so-called dry cells, as compared with other forms of primary batteries, have become and more recognised by users of small electric currents, especially when employed intermittently, as in telegraphy, telephony, medicine, ringing electric bells, &c. These advantages have been discussed and admitted generally in the technical Press, and it is, therefore, unnecessary in this preliminary note to refer to them in detail.

Dr. Lessing's cells belong to the well-known type of modified Leclanché cells, the depolariser being black oxide of manganese and the exciting fluid sal-ammoniac. Each cell is contained in a neat porcelain outer cylinder or jar, highly glazed, and is securely sealed up; lugs on the carbon and zinc plates project through the seal and are provided with convenient binding screws for making connections. The height of each cell is 6·3in., and its external diameter 3·1in., whilst the weight averages about 3lb. 2oz. The arrangements for so sealing the cell that the moisture cannot creep or escape, and the necessary vent for the gases that may be set free, appear to be admirably adapted to the objects in view, and have responded very well to the preliminary tests. Further tests designed to break down these arrangements will try them still more severely.

The following tests were made upon three cells taken at random from a large parcel. The electromotive force (E.M.F.) of each cell as compared with a Latimer Clark standard cell by methods which need not be here described was found to be 1·470 volts, the variations on the different cells being inappreciable. This is fully equal to the E.M.F. that can be expected from this type of cell. The resistances of the cells were next ascertained under very severe conditions, viz., when generating heavy currents, varying from 2·25 to as much as 3·75 amperes. Notwithstanding the severity of the test the resistances were found to have the following very low values for the above size of cell: No. I. cell=0·222 ohm; No. II. cell=0·166 ohm; No. III. cell=0·121. Each resistance given is the mean of four measurements taken with currents varying within the above-named limits.

The cells were then discharged in series through a constant external resistance for 45 hours continuously, the currents given

* Preliminary and further reports by Dr. R. Mullineux Walmsley.

Digitized by Google

varying from 113 milliamperes at the start to 36 milliamperes at the end of the test. These currents are much larger than the cells would ordinarily be called upon to give in any of the cases cited above, and the fact that they were maintained for such a long period without the cells being allowed to recuperate by intervals of rest augurs well for the practical use of the cells. Measurements of E.M.F. and resistance were made at intervals during the discharge. The details need not be given in this preliminary note, but it may be stated that at the end the E.M.F.'s were 76·2, 78·7 and 74·7 per cent. of their respective values at the beginning of the test, whilst the average resistance had only risen to a little over 0·4 ohm per cell. The cells were next allowed to rest for five days, during which the E.M.F.'s returned to 99·0, 99·4 and 92·9 per cent. respectively of the before-named initial values. On discharging continuously for a further period of 24 hours through the same resistance as before, the current fell from 108 milliamperes at the start to 80 milliamperes at the end of the time. Simultaneously the E.M.F.'s had fallen to 72·3, 74·0 and 68·8 per cent. respectively of the value at the commencement of the first test.

It may be remarked, in passing, that the variations in the fluctuations noted in the values of the E.M.F.'s show how very necessary it is in tests of this nature to discharge more than one cell under precisely similar conditions if reliable deductions are to be made of the general behaviour of the cells. Experiments, such as are sometimes made, on single cells may give very misleading results, owing to the particular cell experimented upon being either above or below the average, for it is impossible for any manufacturer to ensure absolute uniformity.

The above tests, which are merely preliminary, show that Dr. Lessing's cells compare very favourably indeed with other forms of dry cells as shown by published tests. Further tests are now being made under varying conditions on all the principal points which are of importance in connection with the use of primary batteries as current generators for small currents.

The following report is a continuation of a preliminary one dated October 31, 1895, to which reference should be made for various descriptive details which will be found therein. The further tests, which will be dealt with presently, were designed chiefly to try the behaviour of the cells as current generators under different and varied conditions, and were all completed before Christmas, but private circumstances have prevented the writer from making his report until now. It will be unnecessary to repeat generally what has been already said in the preliminary report, but perhaps attention may again be drawn to the importance of not making deductions from the behaviour of a single cell. All the subsequent experiments emphasise strongly the remarks previously made on this point, and in these experiments *three* cells were always discharged simultaneously under precisely similar conditions, and measurements were taken on each cell separately. The only doubt regarding the advisability of this course is as to whether *more* than three cells ought not to be used to get fair measurements of the average behaviour of the type of cell under test. The E.M.F.'s were obtained by comparison with a standard Latimer Clark's cell by means of a condenser and sensitive ballistic galvanometer. Both charge and discharge readings were taken, and the usual well-known precautions were adopted, the actual E.M.F. at the moment of breaking circuit being obtained by taking timed readings and plotting the results on curved paper. The resistances were obtained by measuring the P.D. just before breaking the circuit and calculating in the usual way. Some remarks will be made on this subject later on. For convenience, the tests may be referred to in two groups, namely, those in which the current was kept on continuously and those in which the currents taken were intermittent. The former will be described first.

Continuous-Current Tests.

In these tests, unless otherwise mentioned, the current was kept on continuously day and night, except that the circuit was broken occasionally for about a minute at a time to enable readings of E.M.F. to be obtained. It will, perhaps, be sufficient to mention three sets of tests.

In the first set three cells were discharged through a constant external resistance, which was such that the current at starting was nearly 500 milliamperes or 0·5 ampere (more exactly, 435 milliamperes), a very large current to take from cells of this size. Notwithstanding this, the cells maintained the current fairly well for rather more than six hours, during which time the fall of the current was less than 7 per cent. Shortly afterwards the cells fell off very rapidly, but their resistance at the end of the six hours was less than 0·2 ohm per cell.

In the next set three fresh cells were discharged through a larger constant external resistance such that the value of the current, after the cells had been at work a few minutes, was 42·5 milliamperes, a value approximating to the currents usually required from cells of this kind. At 27·2 hours from the commencement of the test the current had fallen to 39·4 milliamperes (92·7 per cent. of the above starting value); at 48·7 hours it was still 39·4 milliamperes; at 71·1 hours it had fallen to 37·3 (87·7 per cent.); and at 95·5 hours to 27·6 milliamperes. This last low value was due to the fact that one of the cells had become exhausted. This cell was therefore now cut out of circuit and the external resistance reduced to two-thirds of its value for the three cells. The current from the two cells then rose to 37·6 milliamperes (88·5 per cent. of the first value) and only fell to 26 milliamperes at 178 hours from the start. The two cells were now practically equal in E.M.F. and resistance, and though the discharge was continued for nearly 22 hours longer it is unnecessary to quote further measurements, as for all practical purposes the cells were exhausted.

The E.M.F.'s of the cells were 1·455, 1·470, and 1·466 volts before closing the circuit, and these fell off in much the same percentage manner as the current, though there were variations between the cells. It is not necessary to cumber the report with the detailed figures, but as an example it may be mentioned that at 71·1 hours the E.M.F.'s were 1·280, 1·297 and 1·308 volts respectively, or 88·0, 88·3 and 89·2 per cent. respectively of their original values. The current had fallen off rather more because the resistance of the cell, which was eventually cut out 24 hours later, had already begun to rise. When this cell was cut out its E.M.F. had fallen to 33·4 per cent. of its original value, but the other two cells had only fallen in E.M.F. to 62·0 and 62·5 per cent. of their initial values 74·5 hours later, or 170 hours from the start.

The behaviour of the cells with regard to resistance during these tests with small currents was not easy to examine. To measure the resistances very accurately would have necessitated the taking of much larger currents from the cells for short periods. To this course there are two objections: first, that it destroys the value of the tests for the particular currents under investigation, and secondly, as was ascertained by actual experiment, the passage of these large currents affected quite irregularly the very resistance to be measured, which was sometimes diminished and sometimes increased. The resistance measurements for small currents are, therefore, only approximate. In the set of tests now being described the resistance was less than 0·2 ohm for each cell at starting and remained at that value for over 24 hours. It then began to rise irregularly and in different ways in each cell till at the end of 48 hours it was about 0·5 ohm per cell. At the end of 72 hours it had fallen in two cells, but had risen to over 1 ohm in the third, which was the cell cut out 24 hours later. In a general way it may be said that the resistance fluctuated about the value 0·5 ohm per cell until the cells were exhausted, and that the rise of resistance was a sign of approaching exhaustion more marked at first than the fall of E.M.F.

The next set of tests need not, perhaps, be referred to in such detail. In these a still larger external resistance was employed, such that the value of the current after the first few minutes was 28·4 milliamperes, a current quite large enough for many purposes. After 48 hours the current was still 27·6 milliamperes, and at 70 hours was 26·7. At this time the circuit was accidentally broken for 1½ hours, so that the cells had a short period of rest. The discharge was then resumed, and the current fell off gradually till at 163·5 hours it stood at 21·8. This low value, as in the preceding experiments, was chiefly due to the exhaustion of one cell only. On cutting this cell out and reducing the external resistance proportionately, the current rose to 25·6 and fluctuated between 26·0 and 25·4 milliamperes, until the discharge had continued for 242·7 hours. At 266 hours the current was still 25 milliamperes, but 22 hours later it had fallen considerably and the cells were both exhausted. The E.M.F. and resistance, allowance being made for the more extended periods of discharge, followed the same general course as in the experiments last described.

Two sum up briefly, the tests show that with cells in good condition, currents of from 25 to 28 milliamperes may be taken continuously and without breaking circuit for 260 hours or longer, a result which may certainly be regarded as very satisfactory.

Intermittent-current Tests.

But one of the chief uses of this type of battery is not for the supply of continuous currents but for generating intermittent currents, and it was therefore considered desirable to examine the behaviour of the cells when supplying such currents, but still under conditions more rigorous than would probably be exacted in actual practice. A piece of simple apparatus driven by clockwork, but which it is unnecessary to describe in detail, was therefore constructed, by which the circuit of a battery could be kept closed for 4min. and then opened for the 6 following minutes, to be again closed for 4min. and opened for 6min., and so on for as long as was considered desirable. In this way the whole time of a test was broken up into intervals of 10min., and in each interval the current flowed without interruption for 4min., and during the remaining 6min. the battery was allowed to rest and recuperate.

Two such series of tests will be here referred to. In both cases, for reasons already given, three cells were joined up in series, and the tests made on the three cells of each group simultaneously. In the first series the cells were allowed to discharge through a constant external resistance, such that the current at the end of the second 4min. was 258 milliamperes—a heavy current

Digitized by Google

to take from such a battery for any extended period. The tests were continued for 96 hours. Before any current had been taken from the cells their E.M.F.'s were 1·505, 1·490, and 1·476 volts respectively, and the resistances after the above current had flowed for a few minutes were 0·54, 0·49, and 0·10 ohm respectively. It would thus seem that the first two cells for some reason had both a higher E.M.F. and higher resistance than most of the cells experimented upon, and perhaps on that account may be regarded as somewhat abnormal. At the end of 49 hours the E.M.F.'s had fallen to 79·8, 78·8, and 83·0 per cent. of their initial values, whilst the resistances had increased some 50 per cent.; at the end of the 96 hours the E.M.F.'s were 1·067, 0·935, and 0·766, or 71·0, 62·7, and 52 per cent. of their initial values. It is evident that at this time the battery was practically exhausted for this method of working. Nevertheless, the discharge was continued 50 hours longer, and then the battery allowed a complete rest of 23 hours. At the end of this period the E.M.F.'s had returned to 67, 70, and 62 per cent. of their initial values, but the resistances of the two first cells (the apparently abnormal ones) had permanently risen to the high value of over 2 ohms, whilst that of the third was now only 0·3 ohm. These tests show that a rest of 6min. is not sufficient to allow the cells to recuperate after supplying such a very heavy current for 4min. continuously.

The next tests to be quoted show that with a smaller current of a magnitude more likely to be demanded in actual practice the relative times allowed for rest and work were more nearly suited to the capabilities of the cells. In these tests, using the same clock-work apparatus as before for making and breaking the circuit, three new cells were taken and caused to discharge through a much larger constant external resistance. The resistance, which was not changed throughout the experiments, was such that the commencing current was 27·6 milliamperes. At the end of 167½ hours, throughout which currents of 4min. duration were followed by rest intervals of 6min., the current had only fallen to 26·4 milliamperes. The cells were next allowed to rest for some days, and were then again discharged through the same resistance. The current started at 27·2 milliamperes, and, at the end of 213·4 hours further work, had only fallen to 25·0 milliamperes. Thus, after 380 hours of intermittent working, the current from the three cells through a constant resistance had only fallen 9·6 per cent. of its initial value. How much longer the battery would have maintained approximately the same current was not ascertained, as the experiments were interrupted by the intervention of the Christmas holidays.

Comparing, however, with the corresponding continuous-current tests, we find that about the same percentage fall of current occurred after 308 hours' intermittent working as after 70 hours' continuous working. In 308 hours the current is actually on for 123 hours. Now, in the "continuous" tests the cells continued to give a good current for about 280 hours or 4 × 70. If we assume the proportion to hold, it would have taken 1,200 consecutive hours to exhaust the cells by the intermittent working. The calculation, though on a probable basis, must only be taken as approximate. Returning to the "intermittent" tests, it was found that the percentage fall of E.M.F. was fractionally (but very slightly) greater than the fall of current, because of the falling off in resistance referred to below.

The remarks previously made on measurement of resistance for small currents apply to these tests and should be borne in mind. At starting, the resistance of the first cell was less than 0·25 ohm, of the second was 0·3 ohm, whilst the resistance of the third was as high as 2·6 ohms. The resistances of the first two cells varied between less than 0·25 ohm and 0·5 ohm throughout the tests, whilst that of the last gradually diminished till it fell to about 0·3 ohm at the middle of the tests and afterwards showed much the same fluctuations as the other cells. The passage of successive currents through this cell therefore had the effect in time of breaking down its high resistance, and the tests show that each cell had a working resistance of 0·5 ohm to 0·25 ohm or less for currents of about 27 milliamperes, a result which may be regarded as very satisfactory. In the preceding tests with heavier currents, where it was easier to make the resistance measurements, the fluctuations were wider and extended from 0·1 ohm to 0·79 ohm until the cells began to get exhausted, when the resistance in two cases rose rapidly, and in the third fell to below the mean value.

The above tests show conclusively that these cells are admirably adapted for generating intermittent currents of the magnitude usually required for many purposes, such as telegraphy, telephony, ringing electric bells, and for medical and other uses. The cells, for their size, have, as a rule, a very low internal resistance and consequently a high efficiency, since only a small proportion of the electric energy is lost in working against the internal resistance. They also have good recuperative power, and if the outside be kept dry the terminals are very well insulated. The so-called test of trying how long a cell would ring an electric bell was not considered necessary, for, at the best, it is unscientific, and can only yield ambiguous results. This is at once evident when we consider that the current required to ring a given electric bell depends largely on the construction of the bell; moreover, much also depends on whether the current is kept at the minimum required to ring the bell or is allowed haphazard to be of any greater magnitude.

One other important property of Dr. Lessing's cells may be referred to in conclusion. Throughout the tests, even when the heaviest continuous currents were being taken, in no instance did a cell show any sign of bursting or of mechanical leakage. In this respect they compare favourably with some similar cells on the market which the writer has seen burst open by the expansion of the materials caused by the heat generated by heavy currents.

The cordial thanks of the writer are due to three of his students, Messrs. J. H. Hughes, C. A. Henderson, and M. Thomson, at the Heriott Watt College, for the care taken in making the experiments, and to the two first-named for constructing the special apparatus required for the intermittent tests.

DIELECTRIC STRENGTH OF OILS UNDER ALTERNATING POTENTIALS.*

BY PROF. ELIHU THOMSON.

In the course of tests made under the direction of the writer some two or three years ago, the interesting fact was noticed that the striking distances of high potentials in insulating oils were in some way variable with the frequency of the current or potential waves, or upon the time during which electric stresses existed in a given direction through the medium. This relation has been confirmed by other and later experiments. The general effect was found to be that discharges at low frequencies are capable of puncturing mineral oil layers up to from one-third to one-half the thickness of an air layer required to just resist puncture by the same discharges, while with high frequencies of equal striking distance in air an oil layer of one-thirtieth to one-sixtieth of the thickness of the air layer was sufficient to prevent discharges. At frequencies such as 125 per second, a potential which would give one-half of an inch spark in air, may puncture from one-third to one-fourth of an inch of oil between the electrodes, while at frequencies of 50,000 to 100,000 a layer of oil of one-fourth of an inch may resist puncture when the spark in air is as much as 8in. The high frequencies experimented with were such as are given by condenser discharges over an air gap, including a primary of a few turns, with a secondary of a single layer of some hundreds of turns immersed in oil. The discharges, in such cases, are not continuous waves, but a rapid succession of oscillatory discharges with dead intervals or periods of inactivity intervening.

The effect of carefully drying an oil was found to increase its insulating power. This was also true to a marked extent when careful filtering was resorted to, a decided decrease of striking distance through the oil with the lower frequencies being observed. It follows from this that all oil used in insulating for high potentials with low frequencies should be kept clean and homogeneous, and free from floating particles.

Variations of temperature of oil did not, in the experiments made, greatly affect the striking distances for a given potential. The general fact, however, that with high frequencies the insulating power of oil layers is, as measured by the striking distance in air relatively to that in the oil, far in excess of such insulating power for low frequencies, seems to be unaffected by the dryness, clearness or temperature of the oil used.

It appears probable, also, that with partially conducting liquids like alcohol and water, the behaviour with high frequencies is more like that of a true dielectric insulator than with low frequencies. As an interesting fact in this connection it may be noted that a high-potential high-frequency coil capable of yielding spark torrents over 30in. of air gap between its terminals, still maintains its discharges even when shunted by a glass tube 1½in. in diameter containing ordinary water, and long enough to bridge the gap.

It is difficult to account for the differences in the effects obtained with high frequencies from those with low-frequency alternating waves. A time lag in the establishment of the full dielectric stress or full electrostatic field in the oil might account for the phenomena. According to this hypothesis if two electrodes under oil, separated a certain distance, instantly acquire a difference of potential, this potential would not with equal rapidity strain the oil to the full extent. It might be assumed that the polarisation of the oil molecules requires time; or, it may be that only such part of the electrostatic field as is due to the ether is first established after electrification and that the increase of such field, due to the molecules of the substance, such as interposed oil, is subsequent to the former. If this were so, the establishment of an electrostatic field at high rates in oils would present analogies with the case of magnetic fields in iron or metals. It would also follow, if the sup-

* From the *Electrical Engineer* of New York, February 12th.

Digitized by Google

position of a lag as above be true, that in condensers such as those using oil as a dielectric, the capacity would be less the higher the frequency. Again, if any such lag as is assumed exists, it would probably vary with different insulating media, and it may depend upon the molecular state, as viscosity, for example. Observations of the oil space between the immersed electrodes by polarised light could probably be used with certain media to detect any differences in time of establishment of electrostatic stress with different frequencies, it being well known that under high stresses certain insulating liquids become strongly affected in their optical properties, with rotation of polarised beams of light traversing them. If the optical effect noticed should be less in the case of high frequencies than with low rates it would indicate a probable lag of the kind assumed. Similar studies, using solid dielectrics like glass, mica, &c., would also be desirable. Should the results be negative it would be necessary to attack the problem in some other way. M. P. Janet, about a year or more ago, in a communication to the Paris Academy of Sciences, gave the results of his investigation of the properties of mica. He found that it did possess, with rapid oscillations, what might be termed a dielectric hysteresis. Such a property may exist to a more marked degree in oils.

In the tests of the power of oil layers to withstand puncturing by high potentials, a curious effect was noticed, which was that discharges under oil passed far more readily between balls than between sharp points. In other words, with any given difference of potential between the immersed electrodes, as measured by the air spark obtainable, pointed electrodes could be brought much nearer than balls without provoking puncture. With balls of half an inch diameter as terminals and with low frequency (125), potential differences ranging from 100,000 to 150,000 volts, the space between the points could be one-quarter that between the balls. The ratio between the length of spark in air and between sharp points in oil was 10 to 1 at 10,000 volts and 8 to 1 at 15,000, while with balls these ratios fell to 2·4 to 1 and 2 to 1 respectively. When flat plates were substituted for the balls the striking distance in oil was still further increased as compared with the distance with points. The seemingly anomalous action of points under oil, so different from their action in gases or air, is certainly curious, and the usual injunction to avoid points and edges as conducive to electric discharge does not seem to apply in such media as oil, at least when the potentials are alternating and at ordinary frequencies.

In experimenting with discharges in oil uniform results are only to be obtained by using carefully-filtered oil, as ordinarily they contain suspended particles, fibres, &c., which appear to bridge the space between the electrodes and provoke a breakdown due to the non-homogeneous character of the dielectric. It is also necessary to discard oil after arcing has once occurred through it, as it will have become much weaker, owing doubtless to the fine carbon particles set free, and which remain floating ready to be drawn into the space between the electrodes, thus giving rise to loss of homogeneity of the medium.

THE ELECTRIC RAILWAY SYSTEM OF MONTREAL, CANADA.

At the ordinary meeting of the Institution of Civil Engineers on Tuesday, the 18th inst., Sir Benjamin Baker, the President, in the Chair, a Paper was read on "The Electric Street-Railway System of Montreal, Canada," by Mr. G. C. Cuningham, M.Inst.C.E.

The author traced the rapid development in Canada and the United States of the application of electricity to street railways. In the United States in 1888 there were about twenty electrical roads in operation, having a total of 80 miles of track, and working ninety motor-cars, while there were now 10,363 miles of track, on which were operated over 40,000 motor-cars. While this had been the progress in the United States, Canada had not been slow to adopt a system that was manifestly so convenient for the public. Montreal, Toronto, Hamilton, Ottawa, Winnipeg, Brantford Niagara Falls and other places had their electric systems either complete or in process of construction. Almost all the lines were constructed on the overhead trolley-wire system.

In Montreal the electric street railways comprised 74 miles of single line, laid on 41½ miles of streets. A daily service of 140 motor cars, and about 50 trail cars, was now running. The gradients were in many cases very severe. On the streets running at right angles to the St. Lawrence River, there was a continuous rise in most instances, and short sections had gradients of 1 in 10, and even 1 in 8. These gradients were a severe test for the motor cars, but they were overcome successfully, and caused little difficulty.

The ordinary rail adopted was $6_{\frac{7}{16}}$in. in height, and weighed 72lb. per yard. The rails were laid on a foundation of concrete, or imbedded in it, according as block pavement or asphalt was used for the roads. The rails were constructed in complete electrical continuity, and where they passed the power station they were directly connected by copper wiring to the generators. Bond wires were riveted into the web at each joint. To still further improve the return circuit, track return wires of the same size, 0·460in. in diameter, as the line feeders, were riveted into the web at various points and carried back to the generators directly by overhead insulated copper wires. At first earth returns had been used, the rails being connected by copper wire to cast-iron car wheels buried between 7ft. and 8ft. in the soil; but considerable electrolytic action was found to be set up between the earth and gas or water pipes. It was determined not to use the ground for this purpose and to construct a complete metallic return.

The trolley wire used throughout the system was of bare copper, 0·365in. in diameter, carrying a safe currrent of about 440 amperes It was suspended from poles between 110ft. and 120ft. apart at the curb line on either side of the street, at a height of between 18ft. and 20ft. over the centre of each track. In some instances the trolley wire was carried by a central line of posts placed between the double tracks. The current had been at first supplied to the trolley wires connected in one continuous system; but this was now divided into various independent sections, so that trouble on any one was felt there only, and did not affect the others. Each section was fed directly from the power station by feed wires, and had its own system of return wires. The feed wire and return wire mostly used was 0·460in. in diameter, but within a ¾-mile radius of the power station heavier insulated cables were inserted, about 1in. in diameter, carrying a safe current of about 600 amperes. Ten such wires led from the power station, and ten others of same size acted as return-wires, allowing for a total output from the power station of 6,000 amperes. The difference of potential maintained at the generators was 550 volts.

The boiler house and engine room were placed fairly centrally to the system, and near to the Lachine Canal, whence water was obtained for condensing purposes, and to the coal wharves. There were fifteen Lancashire boilers, each 28ft. long by 7ft. in diameter, with double furnaces. They developed each 300 H.P., and carried a working pressure of 125lb. per square inch. The gases from the furnaces, after passing through the boiler flues, returned under the boilers and along their sides to the main flue. They then passed, at a temperature of between 439°F. and 480°F., into Green economisers placed on each side of the chimney, which heated the feed water to about 260°F. The temperature of the gases entering the chimney was between 225°F. and 250°F. The feed water was obtained from the condensing water, and entered the economisers at an average temperature of 90°F. The fuel used was bituminous coal from the Cape Breton mines, of an evaporative power of 6½lb. of water per pound of coal.

The engine and dynamo room was 235ft. long by 89ft. wide. There were six horizontal cross-compound condensing engines developing 600 H.P. each, with a boiler pressure of 125lb. per square inch. The cylinders were 24in. and 48in. in diameter, and steam jacketed, with Corliss valves. The diameter of driving wheel was 22ft., its peripheral velocity at 70 revolutions per minute being nearly 4,900ft. per minute. The total weight of each engine was 85 tons. The engines were placed in a row next to the boiler house, 26ft. from centre to centre, on foundations of cement concrete and brick in cement. Each of the first three engines drove four Edison generators, developing 200 kilowatts apiece. The driving wheels were double crowned, and carried two pairs of belts, driving 41in. pulleys, fixed on the armature shaft of the generator. The three remaining engines drove each a pair of multipolar generators by one 52in. belt on one pulley, 48in. in diameter. The two generators were mounted on the same bedplate, with the pulley between them. The armature shaft and the pulley shaft were in alignment, and were connected by two friction clutches. By this means the generators could be driven together or separately. The generators were supported on a continuous length of foundation wall built in brick and cement, and sufficiently massive to be free from vibration.

The rolling-stock equipment in the summer amounted to 163 motor cars; in winter it was 145 closed cars with double motors, and 14 snow sweepers with triple motors. There were besides, 53 open trail cars and 60 closed trail cars belonging to the former horse system.

The motors developed 25 H.P. or 30 H.P. each, and were all of the single-reduction type, the ratio of the pinion to the gear wheel being generally about 4 to 1. The average speed of the cars was about 7½ miles per hour. Electric snow sweepers, 18ft. long, carried on two pairs of 33in. wheels, were used. To each axle was geared a 30 H.P. motor, a third motor being placed in the car to drive the rotatory brooms.

The cost of working for July, 1895, was almost exactly 3¾d. per car-mile, and that of the power was less than ½d. per car-mile. For the year ending September, 1895, the cost was 5⅓d. per car-mile, the average cost of power being slightly under ¾d. per car-mile.

In an Appendix particulars were given as to the amount of coal consumed and electrical energy developed at the William-street power station, with details of the operation of the system during the past four years.

ON THE GENERATION OF LONGITUDINAL WAVES IN ETHER.*

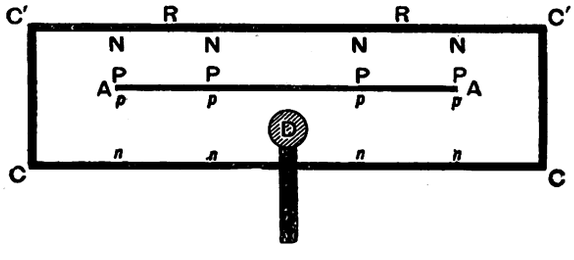
BY LORD KELVIN, F.R.S.

In a short note published in last week's *Nature*, of which a copy is appended, I suggested an arrangement of four insulated and electrified spherical conductors with their centres in one line, giving rise to ethereal waves in the surrounding atmosphere, of which the disturbance in the line of centres is essentially longitudinal. But at any finite distance from this line there must be laminar or distortional waves of the kind expressed in Maxwell's equations. The object of my present communication is to show an arrangement by which a large space of air is traversed by pressural disturbance, or by waves essentially longitudinal, or by condensational-rarefactional vibrations; with but a very small proportion, practically evanescent, of laminar waves.

Let A A be a plane circular metal plate insulated within a metal case, C C C′ C′, as indicated in the drawing. Let D be a discharger which can be pushed in so as to make contact with A.

Let A be charged to begin with, positively for instance, as indicated by the letters P P *p p*, N N *n n* showing negative electricity induced by it. Let now the discharger be pushed in till a spark passes. The result, as regards the space between A A and the roof R R over it, will be either an instantaneous transmission of commencement of annulment of electrostatic force or a set of electric waves of almost purely longitudinal displacement, according as ether is incompressible or compressible.

Hence, if the theory of longitudinal waves, suggested by Röntgen as the explanation of his discovery (for the consideration of which he has given strong reasons), be true, it would seem probable that a sensitive photographic plate in the space between A A and R R should be acted on, as sensitive plates are, by Röntgen rays. Either a Wimshurst electrical machine or an induction coil, adapted to keep incessantly charging A A with great rapidity so as



to cause an exceedingly rapid succession of sparks between D and A, might give a practical result. In trying for it the light of the sparks at D must be carefully screened to prevent general illumination of the interior of the case and ordinary photographic action on the sensitive plate.

The arrangement may be varied by making the roof of sheet aluminium, perhaps about a millimetre thick, and placing the sensitive photographic plate, or phosphorescent substance, on the outside of this roof, or in any convenient position above it. When a photographic plate is used there must, of course, be an outer cover of metal or of wood, to shut out all ordinary light from above. This arrangement will allow the spark gap at D to be made wider and wider, until in preference the sparks pass between A A and the aluminium roof above it. The transparency of the aluminium for Röntgen light will allow the photographic plate to be marked, if enough of this kind of light is produced in the space between the roof and A A, whether with or without sparks.

The new photography has hitherto, so far as generally known, been performed only by light obtained from electric action in vacuum; but that vacuum is not essential for the generation of the Röntgen light seems demonstrated by an experiment by Lord Blythswood, which he described at a meeting of the Glasgow Philosophical Society last Wednesday (February 5th). As a result he exhibited a glass photographic dry plate with splendidly clear marking which had been produced on it when placed inside its dark slide, wrapped round many times in black velvet cloth, and held in front of the space between the main electrodes of his powerful Wimshurst electrical machine, but not in the direct line of the discharge. He also exhibited photographic results obtained from the same arrangement with only the difference that the dark slide, wrapped in black velvet, was held in the direct line of the discharge. In this case the photographic result was due, perhaps wholly, and certainly in part, to electric sparks or brushes inside the enclosing box, which was, as usual, made of mahogany with metal hinges and interior metal mountings. I have suggested to him to repeat his experiments with a thoroughly well closed aluminium box, instead of the ordinary photographic dark slide which he used, and without any black cloth wrapped round outside. The complete metallic enclosure will be a perfect guarantee against any sparks or brushes inside.

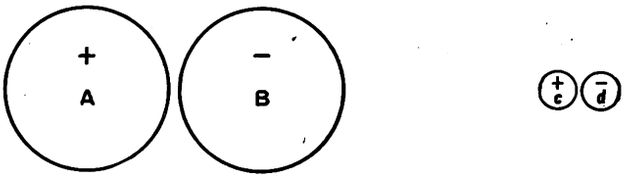
If the arrangement which I now suggest, with no sparks or brushes between A A and the roof, gives a satisfactory photographic result, or if it shows a visible glow on phosphorescent material placed anywhere in the space between A A and the roof above it, or above the aluminium roof, it would prove the truth of Röntgen's hypothesis. But failure to obtain any such results would not disprove this hypothesis. The electric action, even with the place of the spark so close to the field of the action sought for as it is at D, in the suggested arrangement, may not be sudden enough or violent enough to produce enough of longitudinal waves, or of condensational-rarefactional vibrations, to act sensibly on a photographic plate, or to produce a visible glow on a phosphorescent substance.

(Extract from *Nature*, referred to above.)

"*Velocity of Propagation of Electrostatic Force.*

"Dr. Bottomley's note, published in *Nature* of January 23rd, quotes an extract from my Baltimore Lectures of October, 1884, in which this subject is spoken of, with an illustration consisting of two metal spheres at a great distance asunder, having periodically varying opposite electrifications maintained in them by a wire connecting them through on alternate-current dynamo.

"For an illustration absolutely freed from connecting wire and all complications, consider four metal spheres, A, B, *c*, *d*, with their centres all in one straight line;—their relative magnitudes and positions being such as shown in the accompanying diagram. Let each of the four be initially electrified, A and *c* positively, B and *d* negatively. Let the charges on *c* and *d* be so strong that a spark is only just prevented from passing between them by the influence of B and A. Let A be gradually brought nearer to B till a spark passes between them. Will the consequent spark between *c* and *d* take place at the same instant or a little later? It is not easy to see how this question could be answered experimentally; but remembering the wonderful ingenuity shown by Hertz in finding how to answer questions related to it, we need not, perhaps, despair to see *it* also answered by experiment.



"The elastic solid theory restricted to the supposition of incompressibility (which is expressed by Maxwell's formulas) makes the difference of times between the two sparks infinitely small. The unrestricted elastic solid theory gives for the difference of times the amount calculated according to the velocity of the condensational-rarefactional wave.

"But I feel that it is an abuse of words to speak of the 'elastic solid theory of electricity and magnetism' when no one hitherto has shown how to find in an elastic solid anything analogous to the attraction between rubbed sealing-wax and a little fragment of paper; or between a loadstone or steel magnet and a piece of iron; or between two wires conveying electric currents. Elastic solid, however, we must have, or a definite mechanical analogue of it, for the undulatory theory of light and of magnetic waves and of electric waves. And consideration of the definite knowledge we have of the properties of a real elastic solid, which we have learned from observation and experiment, aided by mathematics, is exceedingly valuable in suggesting and guiding ideas towards a general theory which shall include light (old and new), old and new knowledge of electricity, and the whole of electro-magnetism.

"KELVIN."

* Paper read before the Royal Society.

PHYSICAL SOCIETY.

At the annual general meeting of the Physical Society, held on February 14th, Captain W. de W. Abney, President in the chair, the CHAIRMAN after referring to the position of the Society, called upon the treasurer to read the balance sheet. After a discussion on the financial status of the Society, in which a number of members took part, the ballot was held for the election of a President and Council for the ensuing year. The following gentlemen were declared duly elected:—President, Captain W. de W. Abney; Vice-Presidents, Shelford Bidwell, Major-General E. R. Festing, Prof. Perry, G. Johnstone Stoney; Secretaries, T. H. Blakesley and H. M. Elder; Treasurer, Dr. E. Atkinson; Demonstrator, C. Vernon Boys; other members of Council, Walter Bailey, C. V.

Digitized by Google

Burton, L. Fletcher, R. T. Glazebrook, Prof. A. Gray, G. Griffith, Prof. G. M. Minchin, Prof. W. Ramsay, Prof. S. P. Thompson, and Prof. S. Young.

The CHAIRMAN read an obituary notice of the late Rt. Hon. T. H. Huxley.

A vote of thanks to the auditors was proposed by Prof. CAREY FOSTER, seconded by Mr. ENRIGHT, and carried unanimously.

A vote of thanks to the officers was proposed by Prof. A. GRAY, seconded by Mr. RHODES, and carried unanimously.

A vote of thanks to the Chemical Society for the use of their rooms was proposed by the CHAIRMAN and carried by acclamation.

The meeting was then resolved into an ordinary science meeting, and a Paper on

The Determination of High Temperatures by the Meldometer,

by Prof. RAMSAY and Mr. EUMORFOPOULOS, was read by the latter.

The meldometer, an instrument invented by Dr. Joly, of Dublin, consists essentially of a thin platinum strip which can be heated by the passage of an electric current. Small fragments of a solid substance are placed on the platinum strip, and the temperature at which they melt is deduced from the length of the platinum strip, which has been previously calibrated by means of solids of known melting point. The authors have used gold for the purpose of calibrating the strip, and have assumed Violle's value, 1,045°C., for the melting point of gold. A number of measurements have been made of the melting point of salts of sodium, lithium, strontium, barium, calcium and lead. The results obtained, however, differ considerably from those of Haycock and Neville, and the authors have not been able to account for these differences.

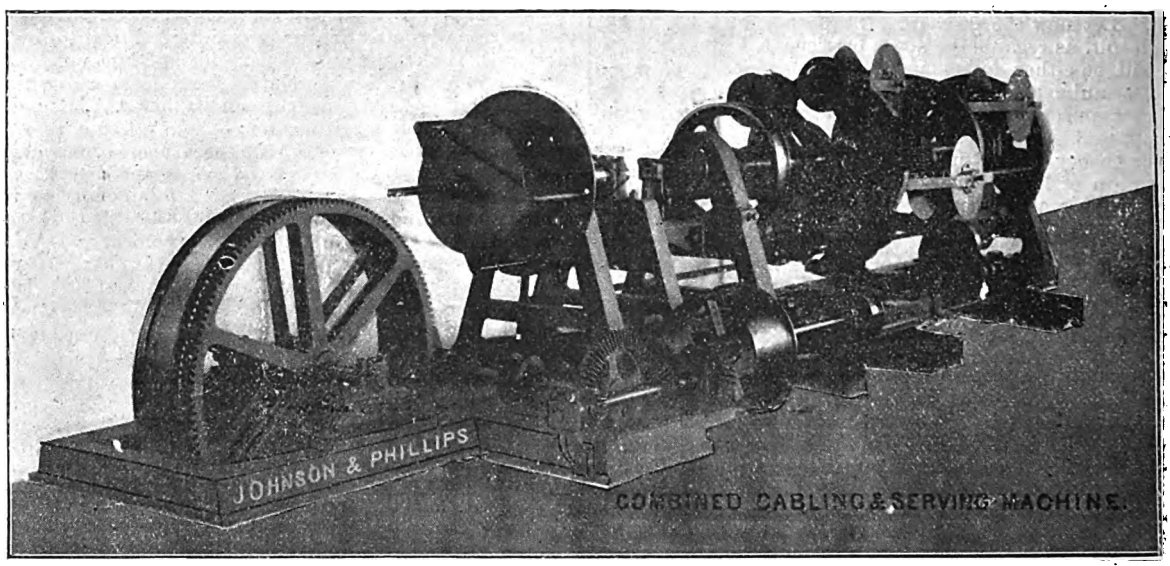
Prof. RAMSAY said the chief advantage of the meldometer was that only a very minute fragment of the substance was required for the measurement, so that extreme purity of the sample could be secured. There was the disadvantage, however, that many substances undergo some change when heated in air. In reply to a question from Mr. Blakesley, Prof. Ramsay said that the property of the platinum which was used to measure the temperature was its expansion.

Mr. CAMPBELL asked whether the zero of the instrument was found to be constant. In Cardew voltmeters it often took several hours for the needle to come back to zero after heating.

Mr. EUMORFOPOULOS, in reply, said that the zero was constant to within a quarter of a degree.

COMBINED CABLING AND SERVING MACHINE.

The machine which we illustrate this week is made by Messrs. Johnson and Phillips, and is arranged for cabling seven wires, *i.e.* laying six wires round one, and at the same time laying a yarn in the recess formed between each pair of wires, so that when the cable is taped it forms a more perfect round. The machine is erected on a strong cast-iron bedplate, and the six wire bobbins (arranged in two bays) are carried on forged wrought-iron flyers between three discs, the third disc also carrying the six yarn bobbins. The central hollow steel shaft runs in a large gun-metal stepped bearing at one end, and the "lay-head" end and the centre disc run on anti-friction rollers. The draw-gear is driven from the "lay-head" end of this shaft by means of a belt driving on to a countershaft carried from the bedplate of the machine. The motion is transmitted to the draw-through drum by means of a spur and bevil gearing, change wheels being provided to give the requisite length of "lay" for the different sizes of wires. The taping head is designed to serve various widths of tapes, and for that purpose is driven by means of coned pulleys, which allow the "lay" and "lap" of the tape to be adjusted very minutely. The bobbin of tape, as will be seen, is arranged concentrically with the cable, the tape being led from the bobbin by means of a series of rollers, &c., down through a slotted guide on to the cable. The wire bobbins are each arranged to hold one mile of gutta-percha covered wire, and the yarn and tape bobbins respectively hold sufficient tape to "worm" and "serve" this length of cable. The diameter of the tape bobbin is 21in., the radius described by taping head, measured over the guide rollers, is 16in., and the speed of this head is about 500 revolutions per minute. The central hollow shaft is 3in. diameter and runs in large gun-metal stepped plummer blocks, having bearings two and a-half diameters long. All the bobbins are provided with means for adjusting the tension on the various wires, yarns, &c., as may be desired. The finished cable is led from the draw-through drum on to a receiving drum placed a few feet distant from the cabling machine, from which it is driven by means of a belt. This apparatus is provided with an automatic guiding-on and flaking gear, which is not shown in the illustration.



PARLIAMENTARY INTELLIGENCE.

LIGHT RAILWAYS BILL.

On Thursday evening last week a Light Railways Bill was introduced by Mr. Ritchie and read a first time.

Mr. RITCHIE said the question of greater facilities in railway communication was before the House last Session, when he believed there was a general expression of opinion that Parliament ought to endeavour to supply some less costly means than the existing law allowed for providing more extensive railway accommodation. The Government did not put forward their proposals as a panacea for the evils of agricultural depression. But it was the duty of the Government to do all in their power to remove any impediments which they thought interfered with the development of agriculture, and it was with that view they proposed to introduce the Light Railways Bill. If they could do anything to bring consumer and producer more closely together—if they could make more easy the distribution of agricultural produce—they would have done much to help both the producer and the consumer. The Agricultural Department had had for some time past under their charge the production of maps of various counties containing large tracts of country without adequate means of communication. He found that in one county there were 324,000 acres of cultivated land which had no railway within three miles. In another county there were 286,000 acres, in another 128,000 acres, and so on. When Mr. Bryce introduced his Bill last year the complaint which was made of the absence of any provision for help from the State was by no means confined to the right hon. gentleman's opponents. The present Government's view was that in a great number of districts, at any rate, where the railways were most needed they would not be made except with some aid both from the locality and from Parliament. Believing that a little personal investigation and experience would be a very valuable aid in dealing with this question, he, together with Lord Dudley and Sir Courtenay

Digitized by Google

Boyle, went to France and Belgium last year with a view to seeing the nature of the light railways there—how they were made and worked, and how their finance was conducted. In France the light railways were to all purposes secondary railways. In Belgium the system would be more properly described as a great system of steam tramways. The main roads were used for the lines, although occasionally a strip of land by the side of the road was taken, or a short cut across country was made, to avoid a difficulty. They had very few signals and hardly any stations. The branches leading to particular farms or centres of industry which had to be served were simple and inexpensive, and the loading and unloading of trucks was carried on in simple sidings on the roadside, where the farmers' carts and waggons were drawn up. The Bill of the Government would, of course, provide for either of these two plans being adopted. In Belgium these railways were made at an average cost of about £3,000 a mile, including rolling stock. He found that in Belgium the light railways travelled with the greatest ease up gradients of one in 22 and round the sharpest curves. The development of this system in Belgium had been very great. Within the last ten years over 1,000 miles of railways had been completed and were in working order; and he was told that projects were now under consideration for another 1,000 miles, which would probably be approved and in operation in a short time. In Belgium the money for the light railways was provided by the State, the province, the commune, and outside subscribers in conjunction. In 1894 the average profit was 2·91 per cent. In England the main difficulties hitherto had been two—first, the unwillingness of Parliament to authorise the compulsory acquisition of land otherwise than by a scheme directly approved by Parliament itself, and the cost of obtaining that approval. The second difficulty had been the expense of the requirements for the public safety enforced by the Board of Trade. As regards the requirements for the public safety, the public must make up their minds that, if they desired to have these railways, they must of themselves exercise an amount of caution, and not insist upon those elaborate precautions which, on trunk lines, where trains were run at great speed, might be necessary. The Government also proposed not to require the sanction of Parliament to the compulsory acquisition of land for the purpose of these light railways. Under this Bill a Light Railway Commission, consisting of three persons, two of whom it was hoped would consent to serve without pay, was to be set up. The Government desired to have on the Commission gentlemen who would act with considerable knowledge of the whole subject in the interests of the community. It was not intended that this Commission should be a mere formal department of the Board of Trade. What would be the mode of working of the Commission when a scheme was presented to them? They would have to satisfy themselves that all persons interested had been consulted; they would determine the expediency of the application, elaborate its details, and after consideration of all objections laid before them they would reject the scheme or submit a draft order for the confirmation of the Board of Trade. As to the action of the Board, they would give notice of the effect of the order, consider any objections lodged with them, and confirm the order with or without modification; and the order when confirmed would have the same effect as if enacted by Parliament. They hoped that in the bulk of cases there would be no necessity for more than one local inquiry, but they did not shut out the possibility. The Bill guarded against any attempt to apply the machinery of the Bill to the promotion of great lines of railway. It also provided against lines being made on a cheap and easy system which would unreasonably and improperly compete with existing lines, which had been formed and built under much more costly conditions. The Lands Clauses Consolidation Acts would be incorporated in the order, but, instead of the difficult and expensive process of deciding as to value under the Lands Clauses Consolidation Acts, all matters in connection with them would be determined by a single arbitrator appointed by the Board of Trade. With regard to finance, it was provided in the Bill that local authorities might themselves construct and work light railways either alone or jointly with other local authorities. The Government believed that Parliament might and ought in many cases to join with local authorities in giving financial aid. The Government rejected the systems of State guarantees and State ownership. They proposed to devote to the objects of the Bill £1,000,000 sterling, which would be available in two different ways. One portion would be available for special advances under special circumstances, another would be available for the granting of loans to facilitate the making of these lines. The Bill proposed that an existing railway company should undertake the construction and working of the line. The total amount contributed by the Treasury must not exceed 25 per cent. of the whole capital required for the making of the line. Two conditions were necessary before the State gave its aid—namely, that 50 per cent. of the capital required should be subscribed by way of share capital, and that 25 per cent. of that capital should be subscribed outside any public authority. The Government must be satisfied that all parties interested in the matter were becoming partners in the undertaking. He hoped and believed that the existing railway companies would be large factors in the success of their proposal, and would recognise that the light railways would become feeders of their own lines. They hoped for co-operation from the road authorities. The interests of the landowners would be adequately safeguarded, and their private rights would not be infringed, nor would these rights, he hoped, be unduly pushed, because if these light railways were a success there was no one who would derive greater benefit from them than the existing landowners. The Government, therefore, expected their co-operation, and also that of the public, who, he trusted, would consent to some relaxation of the precautions hitherto taken.

Mr. BRYCE said this Bill differed from the Bill of last year in three points—(1) In the creation of a Light Railway Commission; (2) in the power given to local authorities; and (3) the giving of a subsidy from national sources. He did not feel any objection to allowing the local authorities to subsidise the lines provided proper safeguards were taken. Then, as to the Imperial subsidy, those who came forward with a gift always had an indulgent House, and therefore he should not be surprised if this proposal was received with favour. They must remember, however, that they were inaugurating a perfectly new policy. An appeal was sometimes made to the practice of Continental countries, but in all countries of the Continent the State had always taken a much more active part in railway construction than it had done here, and in many instances it was the owner of the railways. One of the causes of the greatness of our railway system was that we had relied so much on private enterprise. Our railways, made at immense cost, were at present enjoying great prosperity, and therefore he thought we ought to be loath to embark on the new policy of State railways. He hoped before this proposal was approved by the House—if it was ever approved—these considerations would be very carefully weighed and set against those temporary temptations which were no doubt strongly felt by a good many of his friends. Besides our hereditary policy in the matter there was another point worth attention, and that was that the entry of the State would necessarily be a check to voluntary action. Last year when the late Government introduced their Bill they had every reason to believe that the great railway companies were prepared to make these lines without any subsidy. It was quite plain that now no company would make a line without getting a subsidy if they saw the slightest chance of getting one, and therefore, so far, this plan would operate actually as a discouragement to the action which railway companies would otherwise have taken of their own accord.

Mr. MURDOCH doubted the wisdom of having a different gauge for the light railways. He believed such a course would add to the cost of the carriage of agricultural produce.

Mr. CHANNING congratulated the President of the Board of Trade upon the general construction of the Bill. He thought the suggestion of a Light Railway Commission an exceedingly happy one. It should be an essential part of the scheme that any company starting a light railway should have the right of obtaining access to existing railways. It was in his opinion of great importance that where money was advanced by the Treasury for local objects the local authority should be brought into the operation in some form of guarantee. The policy of spending this money in the form of gifts without any conditions whatever should be looked upon, after Irish experience, with caution and reserve.

Mr. RADCLIFFE COOKE wanted to know, however, whether there would be any provisions in the Bill which would enable an existing railway which did not pay to reduce itself to the condition of a light railway, and, if not, whether the President of the Board of Trade would favourably consider an amendment which would give effect to this proposal.

Mr. LUTTRELL said it was useless for the House to expect that light railways could be made without being a burden on either the local rates or the Imperial Exchequer. He believed the railways would do good to agriculture, and he, therefore, welcomed the Bill of the Government, but they should not let the people suppose that agriculture could be relieved in this way without costing anybody anything. The experience of France, Italy and Germany was that light railways were not a financial success.

Mr. RITCHIE, by leave of the House, brought in a Bill, and it was read a first time.

CORRESPONDENCE.

THE ELECTRICAL ENGINEERS AND MILITARY SERVICE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: There is much discussion going on at present as to the actual value of the services of electrical engineers to the nation in time of war; unquestionably, if he is suitably trained for military service, in addition to his electrical experience, he would be a valuable acquisition to our defences; for, generally speaking, the most valuable application of electrical science and mechanical skill to military and naval purposes is one of defence. It must not be forgotten, however, that a most necessary thing for him to understand in the first instance is how to obey. The slightest hitch caused by any neglect of the word of command would probably cause absolute disaster instead of success. He must, therefore, be a soldier as well as an engineer, and thus it requires something more than an engineer to conduct operations of any magnitude. Let us split up our enthusiasts into groups.

1. Cable companies' engineers and their men and assistants. These would be valuable indeed to the Navy and to the submarine mining departments of the Royal Engineers—their practical knowledge of the actual conditions of working at sea would soon enable officers commanding to appreciate them.

2. Telegraph engineers (land). Here again we must see at a glance their utility in the corps of Telegraph Engineers—perhaps one of the finest organisations of the Army, or at least it is one of the greatest usefulness; and we must not exclude telegraphists from this group, who are operators only, and cannot be considered to rank as electricians or electrical engineers.

Digitized by Google

3. Electric light and general electrical engineers, especially those of seaport towns, who are engaged in marine work, could very soon be converted into useful units for submarine mining purposes, their constant contact with nautical men and the knowledge of nautical terms thus acquired, and their readiness in the handling of ropes, how to tie a knot, or make a splice, without an argument being necessary, making them a welcome addition to the submarine mining department. Divers also are required for this work. There is, in fact, a use for every branch of electrical knowledge in submarine mining, but each individual should be able to keep his sea legs on also.

The three general classifications are drawn up merely to point out the direction in which the services of an engineer could be turned to useful account most readily, and no doubt this is the actual object of the Institution of Electrical Engineers in bringing forward this matter. The question of decorations and military honours forms no part of it, being a secondary consideration only, and hardly worthy the consideration of men on whose efforts the success or failure of a defence may depend.

The Telegraph Corps of the Royal Engineers is an excellent one, and has done good service to the Army as an auxiliary, and no engineer whose lifetime has been spent in this class of work should think of joining the submarine mining branch without some special reason for so doing. On the other hand, every type of electrical engineer would be of value for submarine work after a course of training. Nor must we neglect mechanical engineers also. The demands of this department (submarine mining) may be classed as follows :—

Marine engineers, for the rapid and efficient working of the steamers used, or miners as they are called.

Cable engineers, for the laying and under-running of cables and for completing the necessary repairs; this includes all the necessary men such as divers, splicers, &c.

We then come to the land-service departments, where the search lightsare to be dealt with, the testing station and test rooms to be designed and attended to, &c.

Now, to be an officer in any work such as above mentioned the person who offers himself as such must be thoroughly acquainted with the details of the work in hand, and this can only be acquired by a proper course of study. Clearly, then, the most useful effect would be produced by our electricians not forming a body in themselves, but by being attached to one or other of the above.

No doubt the War Department would be very pleased to welcome them in their proper stations. The officer must, however, do something more than this; he must seek out from the men in his employ, or with whom he may become associated in any way, those most fitted to form a useful addition to the rank and file, for in this, as in everything else, the men form no small part in the consideration of ultimate success. It has a pleasant ring to it, when speaking of an appointment classing one as an officer; but in submarine mining work the officer must be a man also, and not be ashamed of lending a hand when hauling in a muddy cable, or in laying out a new one, the latter operation being a decidedly uncomfortable one on a hot day, when the composition protecting the armoured cable has a habit of finding its way to the eyes and face of the operator, and requiring a very stout heart to cease from grumbling at cables in general, and the composition in particular after the work is finished for the day or night, as the case may be. Our electrical engineers would probably open their eyes very wide if they knew the truly scientific method carried on in all submarine mining work in England. It is not flattery to say that it is the finest in the world, and further, it is conducted with a skill only brought about by the most careful study and training. No doubt the uninitiated might regard the failure of a mine, which occasionally occurs, as a thing he would soon put right when he brings his skill to bear upon it, but only those acquainted with the work know the many little difficulties which may occur, tending to upset previous calculations or plans so nicely laid out on shore, and which often require the greatest coolness and knowledge of circumstances to surmount. It is probable that our engineers might with credit to themselves become pupils of the Submarine Corps of Engineers, and those who aspire to be in charge of the electricians and their work will find plenty of scope for their energy and abilities. Let our engineers, therefore, search the records of the Corps of Royal Engineers, and they will be surprised at the skill already existing even in the rank and file of a body of men whose officers have in the past, and probably still contain, some of our best electricians, who further combine a wide knowledge of human nature with their scientific education, and of the kind necessary for military and naval operations.—Yours, &c.,

W. H. Preece.

Bedford.

THE DISCOVERY OF THE ELECTRIC ARC.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In No. 925 of your esteemed journal we found a letter by Mr. W. Perren Maycock, in which he states that the electric arc was discovered by H. Davy. Without desiring to diminish the high authority of this celebrated English physicist, we cannot abstain from informing him that in the year 1802 a Russian professor, W. Petroff, of the Medical Academy of St. Petersburg, discovered the so-named voltaic arc, using a battery of 4,200 volta cells, which discovery he described in his work "Galvani-Volta Researches," &c. Many experiments of this able explorer, amongst others the electrolysis of water by means of copper electrodes and volta cells, have been repeated by Prof. N. Egoroff, of St. Petersburg, at the meeting of the Russian Physical-Chemical Society.*—Yours, &c.,

A. Smirnoff,

February 19, 1896. Editor of *Electrischestwo*.

[Without in the slightest degree disputing the great merits of Prof. Petroff, or the importance of the researches he made in 1802 (and which were published in Russian in 1803), it suffices to remark that Davy's experiments on the arc began in 1800 (as witness his Papers in *Nicholson's Journal* and in the *Philosophical Magazine* of 1801). In 1802 Davy had already shown the arc light in the theatre of the Royal Institution, using a battery of 150 pairs of plates.—Ed. *E.*]

LEGAL INTELLIGENCE.

Lazare, Weiller, and Co. v. Bolton and Sons.

This case, which was reported in *The Electrician* for February 7th and 14th, came again before the Court on Friday last for the assessment of damages. It will be remembered that Mr. Justice Mathew held that there had been a breach of contract on the part of the defendants, and, further, that the plaintiffs had repudiated the obligations imposed upon them by a collateral agreement.

For the plaintiffs Mr. WALTON, Q.C., now urged that the actual net profit which the plaintiffs would have made upon the contract was £5 per ton. Since June, 1895, the date of the breach of contract, the plaintiffs had only sold 83 tons per month, at a loss of £2 per ton. In five years that would be £9,960. Then there was a loss of £5 per ton upon the balance unsold—namely, 7,220 tons, and a loss of profit of £35,100. That was the basis upon which he estimated the damages.

Sir E. CLARKE, for the defendants, said that the bargain was that the plaintiffs were to make some concession in order to beat down foreign competition, and they had not done so. The contract, therefore, came to an end. There were matters of principle to be decided before elaborate inquiry as to damages were gone into.

Mr. Justice MATHEW said the question of damages must be reserved until the questions of principle had been decided in the Appeal Court, and this course was agreed to.

Walter and others v. the Central News.

In the Court of Appeal, on Monday, the Master of the Rolls and Lords Justices Lopes and Rigby were asked to grant leave to appeal against certain interrogatories being insisted upon. As our readers are aware, the main action is of considerable public interest, and has been brought by the proprietors of *The Times* against the Central News (Limited), an organisation which supplies items of information to the Press, in respect of certain telegrams which the latter had sent the former for publication in that journal. The telegrams in question purported to have been sent to the defendants by their special correspondent at the seat of the Japanese Chinese war, and the ground of complaint by the plaintiffs was that the telegrams supplied to them by the defendants were not the actual telegrams that the latter received from their correspondent, but were amplifications and concoctions of the original telegrams. The plaintiffs

* See *Journal* of this Society for 1894.

Digitized by Google

had administered some 20 interrogatories to the defendants, about 18 of which had been allowed by Mr. Justice Cave.

On the part of the defendants, leave to appeal against the learned judge's decision was asked, on the ground that the interrogatories were administered by competitors for news, who were seeking to obtain information as to the way in which the defendants conducted their business.

Their Lordships refused to give leave to appeal, and said it was only in very strong cases, involving evident injustice, that they would interfere.

TRADE NOTES AND NOTICES.

[Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.]

SPECIAL NOTICE.—The 1896 (fourteenth annual) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is NOW READY. The published price of the Directory and Handbook is 7s. 6d., post free 8s. 3d., abroad 9s. The book is greatly enlarged, is quite up-to-date, and includes the new Board of Trade Regulations issued February 6th.

NEW BOOKS AND EDITIONS.

The following New Books and Editions can be obtained of the Booksellers or direct from the Publishing Offices:—

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett *(now ready)*. Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"THE WORK OF HERTZ."—By Dr. O. J. Lodge, with many original illustrations, price 2s. 6d. nett, is now ready.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

"ELECTRIC MOTIVE POWER."—A new work, by Mr. Albion T. Snell with this title, is now ready, containing the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d. post free (abroad 11s.).

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by Messrs. W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—By Mr. F. Marten Weymouth is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

'THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.), Prospectus on application.

"PRACTICAL NOTES FOR ELECTRICAL STUDENTS."—By Messrs. A. E. Kennelly and H. D. Wilkinson, price 6s. 6d., post free.

"THE ART OF ELECTROLYTIC SEPARATION OF METALS."—A second issue of Dr. Gore's book is now ready, price 10s. 6d. post free.

"ARMATURE WINDINGS OF ELECTRIC MACHINES."—By H. F. Parshall and H. M. Hobart. This work has been compiled from Notes made by Mr. Parshall in his capacity as chief Designing Engineer of the Edison and General Electric Companies of America, and is intended to serve as a working treatise on dynamo design. Large 4to, 370 pages, 140 full-page illustrations and 65 full-page tables. 30s., post free.

"COMPREHENSIVE INTERNATIONAL WIRE TABLES FOR ELECTRIC CONDUCTORS."—By W. S. Boult, price 5s., post free.

TENDERS INVITED.—The Corporation of Sunderland invite tenders for steam engines, continuous-current dynamos, water-tube boilers, fuel economiser, water-softening plant, and cast-iron tank. Specifications, &c., can be obtained at the office of the Borough Electrical Engineer, the Electric Supply Station, Sunderland, and tenders must be sent to Mr. Fras. M. Bowey, Town Clerk, not later than 5 p.m. on Friday, the 13th March. Further particulars are given in our advertisement columns.

——— The Corporation of Bangor require tenders for the construction, supply and laying down of the necessary plant and mains for the installation and supply of electric current within the borough. The contracts are split up into two sections, and plans and specifications may be obtained from Mr. F. Hastings Medhurst, M.I.E.E., Westminster-chambers, 13, Victoria-street, London, S.W., after Monday next. Tenders must be sent in to Mr. W. H. Pritchard, Town Clerk, Bangor, by March 18th. Our advertisement columns contain further particulars.

TENDERS INVITED.—The London County Council require tenders for the supply of electric lighting sundries to Claybury Asylum for one year. Tenders to the Asylums Committee, 21, Whitehall-place, S.W., by Wednesday next.

——— Tenders are requested by Mr. George White-Fraser, consulting electrical engineer, of 18, Imperial Loan Building, Toronto, Canada, for generators and motors to a total capacity of about 1,000 H.P. of each, in various sizes. The machinery is to be installed in a large paper mill in Canada. Our advertisement columns contain further particulars, and tenders should be forwarded promptly.

——— *Extension of Time.*—The time for sending in tenders for the public lighting of Chesterton has been extended to March 31st. Tenders to Mr. J. Spearing, 15, Sidney-street, Cambridge.

——— The Manchester, Sheffield and Lincolnshire Railway Company invite tenders for the supply, during the twelve months ending April 30, 1897, of various stores, including telegraph materials, wire, signal stores, fog signals, screws, rivets, asbestos packing, &c., &c. Patterns can be seen on and after March 9th, on application to Mr. A. W. Longden (storekeeper) at Junction-street Mills, off Ducie-street, London-road, Manchester, and specifications, with forms of tender, may be obtained on and after the same date from the Secretary (Mr. Oliver S. Holt), London-road Station, Manchester, to whom tenders must be sent in by 10 a.m. on Tuesday, March 17th. Further particulars appear in our advertisement columns.

——— The Chelsea Guardians require tenders for supplying and fixing telephones, &c., at their infirmary, Cale-street. Tenders to the Clerk (Mr. W. Miller), 250, King's-road, Chelsea, by March 10th.

——— Tenders are invited for the supply of 12,450 telegraph poles and 15 lots of paper-insulated electric cable for the Direction Générale des Postes et des Telegraphes, 103, Rue de Grenelle, Paris. Tenders must be sent in by March 10th.

——— The Norwegian State Railway Authorities require tenders for the supply of Morse telegraph instruments, Morse keys, lightning conductors, galvanometers, signal bells, &c. Tenders to the Expeditions Contor, Eisenbahn Verwaltung, Jernbanctoret 8-9, Christiania, by March 11th.

——— The Netherlands Minister of Waterways, Commerce and Industry requires tenders for the supply of telegraph poles to the Telegraph Department during 1897. Tenders to be sent to the Minister, The Hague, by March 6th.

——— Tenders are required for the concession for the electric lighting of the city of Lima. Tenders to La Legation de Perou, 8, Avenue Hoche, Paris, by June 1st.

——— The Royal Portuguese Railways Company invite tenders for the supply of electrical apparatus for alarm bells. Particulars from the Company, 28, Rue de Chateaudun, Paris, and tenders to the Ingenieur-in-Chef du Service des Magasins, Compagnie Royale des Chemins de Fer Portugais, Santa Apolonia, Lisbon, by March 11th.

TENDERS ACCEPTED.—The Cuckfield (Sussex) Guardians have accepted the tender of the Private Wire and Telephone Installation Company for providing and erecting telephones in the workhouse premises.

PATENT SPECIFICATIONS.—Particulars will be found in our advertisement columns of an application to be made for leave to amend the specification of Letters Patent No. 4,572 of 1894, granted to Mr. Charles Adams-Randall for "Improvements in Telephonic Transmitters."

PREMISES TO LET.—Our advertisement columns contain particulars of eligible premises to let, suitable for electrical engineering works or supply station, in the Rochdale district.

APPOINTMENTS VACANT.—All whom it may concern are reminded that the applications for the post of electrical engineer to the Queensland (Australia) Government have to be sent in by Monday next. All necessary information can be obtained from the Agent General for the Colony, 1, Victoria-street, Westminster, London, S.W., to whom applications have to be sent in.

DISSOLUTION OF PARTNERSHIP.—The partnership business of electrical engineers and contractors, hitherto carried on under the style of Cooper and Pannett, at Newman-street, Oxford-street, W., and Gray's Inn-road, W.C., London, has been dissolved.

PERSONAL.—Mr. Haydn T. Harrison, M.I.E.E., has resigned his position as manager of the Nalder and Harrison Construction Syndicate (Limited), in order to devote his whole time to his consulting and testing practice. Mr. Harrison's address is now Albany Buildings, 47, Victoria-street, Westminster, S.W.

BUSINESS CHANGES.—In our last issue we called attention to the retirement of Mr. J. D. F. Andrews from the firm bearing his name, and his starting in business on his own account at Putney. We are asked to state that the goodwill, patents, stock-in-trade, fixtures,

Digitized by Google

&c., of the old firm have been purchased outright by the Safety Concentric Wiring Company, and that the business will be carried on by that Company at the old addresses, 15, Marsham-street and (temporarily) 34, Victoria-street, S.W., Mr. J. D. F. Andrews having no longer any connection of any kind with the firm, Mr. E. Jesse Piper is manager to the Company.

LIQUIDATIONS.—A petition has been presented by the Bank of Liverpool for the compulsory winding-up of the Morecambe Electric Light and Power Company (Limited), and will be heard at the County Court, Preston, on March 10th. Messrs. Bolton and Bolton, 14, Kent-street, Kendal, are solicitors for the petitioners.

——— A meeting is to be held at the offices of Messrs. Price, Waterhouse and Co., 44, Gresham-street, E.C., on March 24th, at 3 p.m., for the purpose of receiving an account of the winding-up of the Edison Electric Light Company, Limited.

BANKRUPTCY.—A sequestration order has been made against the estate of William Gray, jun., electric light engineer and contractor and ironmonger, also trading as the Scottish Electrical Engineering Company and Gray and Son (of which the bankrupt is sole partner). Claims to Mr. A. Campbell, agent, Albany-street, Edinburgh, by June 21st. The examination takes place at the Court House, Edinburgh, on March 10th.

FAILURE.—In the failure of P. B. Steele and Co., electrical engineers, of 43, Commercial-street, Dundee, the following list of creditors is published :—

J. H. Holmes and Co.	£76	1	0
Crompton and Co.	69	11	7
Siemens Brothers and Co.	50	18	5
John Harling and Sons	33	13	0
Körting and Mathiesen	31	2	6
Edison and Swan United Electric Light Company	30	10	8
Electrical Company (Limited)	30	3	5
W. T. Henley's Works Co.	25	5	1
Ross and Co.	24	7	4
Bell and Sime (Limited)	20	0	2
Munro's Electrical Manufacturing Company	15	1	8
B. Verity and Sons	11	17	11
Zurich Incandescence Lamp Company	11	2	1
Beanland, Perkin and Co.	10	8	7
General Electric Company	7	1	3
Sunbeam Lamp Company	6	2	1
G. Braulik	5	0	11

The liabilities are £519. 14s. 2d., and assets (after deducting the preferential claims), £64. 4s., equal to a dividend of 2s. 5½d. subject to realisation. The debtors are stated to be offering a composition of 2s. 6d. in the £.

PATENT BEAD RAY DIFFUSERS.—Messrs. D. H. Bonnella and Son, of Mortimer-street, Cavendish-square, London, W., inform us that they have acquired (in succession to Messrs. Bashall and Overton) the sole agency for the United Kingdom for these well-known diffusers.

POLE-FINDING PAPER.—Mr. A. H. Avery, of Tenterden, Kent, sends a sample of his pole-finding paper, which he claims is an advance on anything of the kind previously brought out. The paper is stated to be non-poisonous.

CATALOGUE.—Messrs. Doulton and Co., of Lambeth, have recently brought out a revised edition of their catalogue of stoneware conduits and accessories for underground electric mains. The publication gives numerous illustrations of the Doulton conduit systems in use in London, Manchester, Portsmouth and numerous other cities, and it is interesting to notice how extensively stoneware conduits have been adopted, and to how many systems of electrical distribution they have been applied.

——— A handy pocket price list of continuous current machinery is issued by Messrs. Thomas Parker (Limited) of Wolverhampton. Useful information is given as to the construction of the machines and their efficiency. The list also contains prices and information regarding multiple contact switches and resistance coils, motor-starting switches, &c.

ELECTRO-HARMONIC SOCIETY.—A "Ladies' Night" of this Society is to be held at the St. James's Restaurant, Regent-street, London, W., this (Friday) evening at eight o'clock. An excellent programme is, as usual, provided.

BERMONDSEY (LONDON).—The Vestry have decided to appoint a special committee to consider and report upon the question of applying to the Board of Trade for a Provisional Order.

BIRMINGHAM.—At the meeting of the Markets and Fairs Committee of the Corporation on Friday last, the subject of the lighting of the new Meat Market was under discussion. A suggestion had been made that the incandescent gas light should be adopted ; but after the Committee had received and considered a communication from the Gas Committee, it was decided to adhere to the original resolution to light the market electrically, and to advertise for the necessary tenders. The *Birmingham Daily Post* states that incandescent gas burners were recently tried for outdoor lighting in some of the lamps in front of the Council House, but the result was very unsatisfactory ; the strong air currents and vibration of the lanterns proved most destructive to the incandescent mantles.

BRIGHTON.—At the last meeting of the Lighting Committee it was decided to recommend the Town Council to join the other Corporations in opposition to the application by the Westinghouse Electric Company for an extension of time for the three-wire patent.

BRISTOL.—At the meeting of the Town Council last week the report of the Sanitary Committee on the application of the Bristol Tramways Company for a Provisional Order authorising the construction of tramways in the City of Bristol and Kingswood was discussed. An abstract of this report, and also of the report of the Electrical Committee, appeared in our last issue. Mr. Alderman Cope-Proctor moved the adoption of the Sanitary Committee's report, and Mr. George Pearson proposed an amendment that the consent of the Corporation be refused unless the Company accepted the condition that every future extension must be upon the principle of the electrical energy being supplied by the Corporation. After a long discussion Mr. Pearson decided to remodel his amendment as follows :—"That a committee, consisting of the Sanitary and Electrical Committees, be appointed to consider, and report upon, the desirability of introducing the overhead trolley system in the city, and, if such system should in their opinion be sanctioned, to report upon the terms on which such sanction should be given." The Sanitary Committee's report was then adopted.

CABLE MESSAGES BY TELEPHONE.—The Liverpool Chamber of Commerce has succeeded in obtaining permission for cable messages to be transmitted by telephone after 6 p.m. to private addresses. The arrangements come into operation on Monday next.

CHURCH LIGHTING.—The Augustine Church, Edinburgh, has just been fitted up for the electric light. The installation has been carried out by Messrs. Lowdon Bros., of Dundee.

COUNTRY HOUSE LIGHTING.—Messrs. Drake and Gorham have obtained a contract for the electric lighting of Bidborough Court, the residence of Mr. Henry J. Wood.

DOUGLAS (ISLE OF MAN).—In reference to the electric lighting of this town we have received a further letter from Mr. Gillmore, who assures us that he never intended to convey the impression that the electric light was three times the cost of gas in all cases. When using this comparison he was referring to the lighting of the Promenade only, and the coefficient 3 would, he thinks, fairly fit the facts in this instance, because the small plant required for this single job could not be worked economically, and because the Gas Company of Douglas light the Promenade at a specially low rate. We trust we have now made Mr. Gillmore's contention clear. We have also received a letter from Mr. Berry, who takes exception to Mr. Gillmore's contention regarding the cost of the electric light, and puts it that no such limitation was connected with the original assertion that electricity costs three times the price of gas. Feeling runs high at Douglas on this electric lighting question, and it is very cogently pointed out by Mr. Berry that remarks signed "G. Gillmore, Electrician," would be taken up by opponents of electric lighting and made the most of. After the elections the subject will doubtless have more dispassionate consideration.

EALING.—Owing to the increasing demand for electric current the District Council has decided to put in additional plant at their electricity station. The number of lamps connected is 5,627, while there are applications for 531 additional in hand.

EDINBURGH.—At the last meeting of the Edinburgh and Leith Gas Commission, Bailie Anderson, in moving the adoption of the minutes of the Works Committee, which recommended an outlay of £13,000 for laying a new gas main to the south side of the city, said that the supply on the south side was very defective, and unless they were prepared to supply the gas which was required they would be playing into the hands of the promoters of electric lighting. Mr. Eunson thought the matter should be delayed, because there was a very strong desire in the district to introduce the electric light. Lord Provost M'Donald (the Chairman of the Commission) said he lived in the district, and acknowledged that the supply of gas was so bad that he was compelled to keep three burners alight in his dining room, but he only got the light of one burner from the three ! He would say they should not be at all afraid of the electric light !

Mr. E. Monkhouse, the Corporation's electrical engineer, read a Paper before the Royal Scottish Society of Arts on Monday, the subject being "The Distribution of Electricity in Edinburgh." He stated that ten miles of low-tension and seven miles of high-tension mains had been laid, and that out of 250 arcs used for street lighting, 61 only were on the high-tension system. On the advice of their consulting engineer, Prof. Kennedy, the Corpora-

Digitized by Google

tion had adopted the Ferranti and the Kelvin electricity meters, and found these worked very well. He attributed the low price at which current was supplied to the fact that the policy of the Corporation had been to adopt all the latest means for saving steam and water in the station, the superheater having contributed to a saving of about 15 per cent. of coal; they had cheap and good coals; and the system had been extended in all directions, enabling the station to keep up a fair load all night. Mr. Councillor Mackenzie, who was present on the occasion, said an important factor had been overlooked by Mr. Monkhouse, and that was that the Corporation had taken care to select a good consulting engineer, and a clever, practical man as resident engineer, and had left the work of the station to be done by those gentlemen without themselves meddling in the matter. They had trusted their engineers, and the proof of the wisdom of this course was shown in the success of the undertaking. Lord Kingsburgh was also present, and made the statement that by the exercise of discipline and economy in his own house his bill for electric lighting was, comparing one quarter with another, less than his gas bill had been.

ELECTRICITY IN MINING.—The *Mining Journal* (Perth, Western Australia) states that the Government are in receipt of information from London showing that the Electric Power Company, which is represented in West Australia by Mr. Edmund Mitchell, has lodged the necessary deposit, and that the work of erecting generating plant and cables is to be proceeded with forthwith.

FAREHAM.—The Local Government Board have sanctioned the borrowing of £6,681 by the District Council for electric lighting purposes. This sum includes £4,886 for the purchase of the Fareham Company's undertaking, and the balance is to be expended in providing additional machinery for the station.

GATESHEAD.—A firm of electrical engineers recently applied to the Town Council for liberty to supply electric current within the borough, and this application was discussed at Wednesday's meeting of the Parliamentary Committee. It was decided to instruct the Town Clerk to obtain information from other towns where the electric light had been introduced.

GLASGOW.—The City Council were engaged in the discussion of electric lighting matters at their meeting on Thursday last. The minutes of the Committee on Electric Lighting recommended that the Waterloo-street station should be extended at an estimated cost of about £6,000. The minutes of the Special Lighting Sub-Committee contained a report by Messrs. W. Foulis (manager of the electric light and gas departments) and W. Arnot (city electrical engineer), which stated that they had considered the saving that might be effected by transferring the arc lighting from John-street to the Waterloo-street station, and supplying the lamps from the low-tension mains used for private lighting. This would necessitate new lamps being procured, and the estimated cost of these with the necessary connections was put at £1,300. From the higher efficiency of the plant at Waterloo-street, and also from the fact that the additional current may be generated without extra cost for labour, they anticipated making a total saving of £688, viz., cost of fuel £257, and wages £431. Additional capital would be required for plant at Waterloo-street, but the sum realised from the sale of the building and plant at John-street would probably meet this charge. If these recommendations were adopted the cost per lamp per annum would be reduced to £22. 10s. 1d. The same sub-committee also recommended that it be remitted to them to consider and submit an exhaustive report as to the supply of current for public and private lighting and motive power purposes. After a long discussion the minutes were referred back. ——At a joint meeting of the Sub-committees on Tuesday it was resolved, by way of experiment, to alter eight arc lamps at the Charing Cross end of Sauchiehall-street, and to hang the lamps on overhanging arms, similar to those at present employed at Edinburgh. The Sub-committees are also engaged in preparing a plan for the electric lighting of the main streets of the city. ——At the last meeting of the Tramways Committee it was decided to send a small deputation (including Mr. Young, the tramways manager) to the Continent, for the purpose of visiting various cities where electric traction is employed. This step has been taken in order to obtain information for the guidance of the Committee, and with the ultimate view of adopting an improved system of motive power for the city tramways.

HALIFAX.—The Finance Committee are greatly exercised as to the best means of preserving the elaborate and costly decorations at the Town Hall. As a means to this desirable end the Committee have decided to dispense with the use of gas and to introduce the electric light throughout the building. A sub-committee has been appointed to prepare estimates, &c.

HUDDERSFIELD.—The Town Council, at their last meeting, approved a report as to the lighting of the Market Hall.

HULL.—At the last meeting of the Electric Lighting Committee the Chairman said they had a good many orders for current coming in, and assuming the increase to go on at the present rate they would reach the utmost capacity of their present plant by the end of the current year. A sub-committee was appointed to consider the question of extensions. The engineer presented a report on the suggested reduction in the price of current, and on his recommendation it was decided to make no change at present.

LECTURES.—A lecture was given at the Highbury Quadrant, London, N., on Monday last, by Mr. Percival P. Kipping, traffic superintendent of the National Telephone Company, on the subject of "Some of the latest Marvels of Electricity." The electrophone, phonograph, telautograph, and column-printing telegraph, telephones and a small telephone exchange illustrated Mr. Kipping's remarks.

MULLINGAR.—The electric light is making considerable progress in this town. Numerous isolated electric lighting plants have already been put down by tradesmen, and to keep pace with the times Messrs. Willis Bros. and Co., building contractors, have had a very complete installation put in at their extensive premises. The engines of the firm are utilised for the purpose of generating current, and a battery of accumulators has been put in. The work has been carried out by Messrs. Tuck and Co. (Limited), Aston's Quay, Dublin, under the supervision of Mr. D. M'D. Grosart, electrical engineer.

NEWCASTLE-ON-TYNE.—A poll of the ratepayers on the proposed Tramways Bill of the Corporation was taken last week, the result being adverse to the Bill by 9,656 votes to 9,363.

NOTTINGHAM.—The report of the Electric Lighting Committee, to be presented at the meeting of the Town Council on Monday next, states that, owing to the demand for electric current having greatly exceeded their anticipations, it is absolutely necessary that the generating station should be enlarged, and orders placed for additional plant at once. Several large buildings in the town are being wired, and a supply of current will be required by the autumn, in addition to which there is a steady increase in the number of ordinary customers. The present plant is capable of supplying current to an equivalent of 11,000 8 c.p. lamps, and there are applications for 16,240 8 c.p. lamps. The Committee therefore recommend the Council to put down plant capable of supplying an additional 12,000 8 c.p. lamps. The capital expenditure to date is £50,200, and it is recommended that an additional £40,000 be borrowed, this sum to be expended as follows: Capital already expended but not raised, £5,200; extensions of buildings, £5,430; additional machinery, £13,000; meters, &c., £2,800; extension of mains, £12,570.

PEMBROKE DOCK.—The gas supplied by the Pembroke Dock Gas Company is so unsatisfactory, both as regards quality and price, that the Town Council are seriously contemplating the introduction of the electric light. At a special meeting of the Council on Tuesday a letter was read from the gas company, agreeing to reduce the price from 4s. 2d. to 3s. 11d. per thousand. The question of applying for a Provisional Electric Lighting Order was, owing to this concession, postponed for six months.

RATHMINES (DUBLIN).—At a special meeting of the Town Commissioners on Saturday last it was decided to consent to the proposal of the Dublin Southern District Tramway Company to construct electric trams in the district. The townships of Dalkey, Kingstown, Blackrock, Pembroke, Drumcondra and Clontarf have already agreed to the principle of electric traction.

SMOKE NUISANCE.—At the Westminster Police Court, on Tuesday, Mr. W. R. Renshaw, manager of the Queen Anne's-mansions Lighting and Heating Company, was summoned for allowing smoke to issue from a chimney shaft on the Company's premises. Mr. P. Gye prosecuted on behalf of the Westminster Vestry, and, in defence, Mr. Renshaw said that he had done everything possible to abate the nuisance. He thought it should be taken into account that the furnaces were used for domestic purposes, and saved about 113 ordinary kitchen ranges. The aggregate volume of smoke from these ranges would be greater than that from the shaft. Mr. de Rutzen, however, imposed a fine of £20, and £5 costs.

STAPLETON (BRISTOL).—At the last meeting of the District Council it was reported that the Great Western Electric Light and Power Company had withdrawn their application for a Provisional Order for the district.

STOKE-ON-TRENT.—At the last meeting of the Town Council it was decided to approve the draft agreement with the local tramway Company as to the electrical equipment of the old tramways. It was also decided to offer no objection to the proposed Potteries Extension Tramways Order, provided the promoters agreed to the modifications suggested by the Town Clerk.

SWANSEA.—The Town Council intend to abandon their Tramways Bill and their dust destructor scheme. It is reported that Mr. J. C. Howell has made an offer to purchase the Council's Provisional Order in case Mr. Manville's electric lighting scheme should also be abandoned.

Digitized by Google

WANDSWORTH (LONDON).—The District Board last week again dealt with the question of the opening up of Manor-street and Little Manor-street by Mr. P. E. Singer, without notice having been given to the Board. Complaint was originally made by the County of London and Brush Provincial Company, who have a Provisional Order for the district. The Company pointed out the injustice, after having been put to great expense in obtaining the Provisional Order, and in conforming to the conditions laid down by the Board of Trade and the local authorities, in having to contend against competition of this kind. After discussing the matter for some time, the members ultimately voted in favour of Mr. Singer being allowed to put down a new cable. Mr. Singer's action was described as "local enterprise."

WEST AUSTRALIAN TELEGRAPHS.—The West Australian Government land lines have been out of working order for some days, the breakdown being caused by storms and gales. This accounts for some delay in the receipt of telegrams from the interior.

COMPANIES' MEETINGS AND REPORTS.

City of London Electric Lighting Company (Limited).

The sixth ordinary general meeting of this Company was held at Winchester House, Old Broad-street, E.C., on Friday last, Sir David L. Salomons, Chairman of the Company, presiding.

The MANAGER and SECRETARY (Mr. J. Cecil Bull) read the notice calling the meeting.

The CHAIRMAN said: Gentlemen, I would remind you that it was in Sept., 1892, that this Company actually commenced operations. In August, 1891, we took over the Pioneer Company, with all its assets and surplus funds to continue the work which that Company had not at the time completed. We came in, therefore, to this legacy with a few street lamps erected in Queen Victoria-street and other parts of the City—no private lights were being supplied. You will see by the report that by the end of that year there were a certain number of private lamps connected—something like 20,000, I think. That was done with the Pioneer Company's machinery. During the first two years there was naturally very great difficulty in coping with the demand for current, which increased more rapidly than would have been imagined from the criticisms which appeared in the Press about that time, which were to the effect that the demand in the City for current would be comparatively small, and might not even pay, on account of the light not being required much in the evenings in offices and other places of business. All such predictions have been totally falsified. The demand became so great that there was an enormous difficulty on our part to meet it. We were also confronted with another difficulty—that of having to learn the peculiarities of the district we supply. That, of course, is not singular to the City, but has to be overcome in every district. People in one locality have totally different requirements from those in another, and the electric lighting companies have to discover for themselves what the requirements of their customers are. That experience has been gained by us, and we now know exactly from hour to hour what is likely to be the demand made on our machinery. The third year—last year—found us in a very different position from that of the two previous years. It is true the whole of the machinery was not at work, and if the applications continue to come in week after week as they do at the present time, of course we shall always be requiring more machinery. At the same time, I would point out that our main building was practically completed last year. Instead of working under a temporary roof with an unfinished building, and amid the dust and dirt inseparable from such a state of things (which is not favourable for running machinery), we were able to turn our attention to more important matters. We have now under one roof, I think, the largest installation that exists anywhere. We yet require further time to finish the machinery in course of erection, and with an engineer such as we now possess in Mr. Bailey I am sure we may have every confidence that when the work in hand is completed there will be no cause whatever to complain. At the present time (Feb. 12th) we had connected the equivalent of 202,045 8 c.p. lamps. The applications have reached 213,224, but we cannot connect up directly we receive an application. Out of applications for 213,000 odd lights only 11,000 are waiting to be connected, and the number is being reduced day by day. The period of what I may call constructional anxiety may now be said to have come to an end, and there is scarcely a doubt that, owing to the great support which has been given to the Company by the public in the City, it will succeed. We may regard the City of London Electric Lighting Company as on a thoroughly sound and permanent basis. To prove this point I should like to refer to a point in the accounts to which some critics might make objection.

You will observe that we have again trenched—if I may use the expression—on the premiums to increase the depreciation fund. It might be said that we shall not be able to do this every year, as in course of time the premiums will become exhausted. But here is the strength of our position. If matters go on in 1896 as they have during 1895, and seeing that for only a portion of the past year were we earning money on the whole of the 200,000 lamps, it can easily be calculated that with this number of lamps bringing us in revenue for the whole of the current year there will be sufficient income not only to cover any amount that may have to be placed to the Parliamentary and other depreciation funds, but there may possibly be a surplus. On this point I should not like to make any prophecies, however, although we may express hopes. At least, we may take it that, accidents apart, at this time next year, when appearing before you, we shall be in no worse position than we are to-day, and that there will be no necessity to make any call on the premiums which have been set aside for such periods as that of the past year. Another point to which to call attention is that we have done a work, not for one or two years only, but that we have expended capital which will prove of lasting benefit for many years to come. It would scarcely be fair, after such a heavy capital expenditure, to charge the whole of the depreciation, which can scarcely be said to have begun yet, on the profits of a single year, and your Board thought therefore it was wise to transfer a portion of the premium fund to the depreciation fund; and you will notice that we are permitted out of this Parliamentary depreciation fund to maintain and renew all that is required at our works during the year. Of this money but a comparatively small portion has been expended, so that the transference of this sum from the premiums fund to the depreciation fund does not mean that the money has actually been spent.

The report which has been placed before you is very short and very explicit, and as you are going to receive a dividend presently, the chances are that you do not require so much explanation as you would demand at my hands were no dividend to be declared on this occasion. At the same time, I think it is right you should know what is going on, and I will tell you briefly. There are points shareholders may have overlooked, although those who are accustomed to this class of accounts have probably not done so. One of these is that there is an advantage to the Company of roughly 20 per cent. in the expenses of distribution and generation, relative to the earnings, as compared with 1894, and 30 per cent. as compared with the year before that. But of course this cannot go on for ever, because after a certain point we should be generating the current for nothing. We have not, I hope, come quite to the end of economy in this respect, but I doubt if we shall be able to reduce the cost much below the present figure. There is another item to which I wish to call attention, and about which I may say the larger it becomes the better it will be for the shareholders. I refer to the item of meters. The more we spend under that head the more customers we are getting. There is, if I remember aright, nothing said in the report about the telephone tubes, a very much vexed question in its way, and one that is gradually settling itself. In consequence of the rapid demand for current which has been made in the City it has been necessary to use a great many of these tubes for the drawing-in of cables to supply customers. There are a considerable number of these tubes vacant which we should be willing and pleased for any telephone company to purchase or lease of us. But we have at any rate this consolation, that with the great demand for the electric light from people in the City it has not been necessary to open the streets a second time, which would probably have been the case had not these telephone tubes been laid. You will observe that the actions for vibration have been settled by the purchase of the property to which that action referred, and therefore that dispute has come to an end, and we trust such troubles will cease altogether. So far as I am aware nothing further of the sort has arisen. The expense connected with this action, and also with one or two other matters mentioned in the accounts, the Board having considered it fair to place to the suspense account, spreading it over several years instead of paying it all out of one year's profits. Our auditors concur in this view.

A question has been raised as to whether we could not hold half-yearly meetings and pay interim dividends. I would point out the difficulty and inconvenience of paying an interim dividend, and then discovering at the end of the year that it has not been earned. The case of the electric light companies is very much like that of railway companies—there is a good and a bad half-year. If ever we should get a sufficient income to enable us to safely pay an interim dividend in the first half of the year, clearly it would not be to the interest of the Directors to withhold the money and keep it at the bank. But it may be many years before such a procedure would be considered thoroughly safe. I am just reminded that this applies to the Ordinary shares only. I am sure it would not be the wish of any gentleman present, whatever may be his views in the abstract, to advise your Board to take a step they would deem imprudent at the present time, although they are anxious to see a period when it would be safe to pay a dividend in the first half of the year. Then as to half-yearly meetings, I have to point out that the accounts cannot be rendered until the end of the year. The Board of Trade make it a rule that all accounts shall be made up to December 31st, and to make them up a second time would entail a great deal of expense and work without any advantage being gained, because accounts so rendered would not be final, nor could they be considered as properly audited under such an arrangement. I believe there is a company which, at the time the half-yearly meeting would be held, issues a circular giving the shareholders information as to what has been done in the first six months, and we shall be ready, if it is the wish of the shareholders—and even without your

Digitized by Google

express sanction we might take it to be your wish—to issue, half-yearly, a rough rendering of what has been done during that period. It is not our desire to keep anything back from the shareholders, and I feel sure it is not your wish to put the Company to expense and trouble when nothing can be gained. The duty of the auditors, I may point out, is exceeding onerous They go in the most thorough manner through the whole of our accounts, and without auditors who do their duty in such a manner your security for their corrections is gone. So far, they have received a fee of 100 guineas, and we therefore recommend, and I trust the shareholders will agree with it, that this amount be increased to 125 guineas. The suggestion does not come from the auditors, but from us, I undertake to say that no set of officers have taken so much trouble in looking through what is one of the most important parts of your business than have those gentlemen whom you elected as your auditors last year, and whom, I trust, you will re-elect again. And now, apart from any replies to questions you may wish to put to me, I have only to say that our officers and employés have given us every possible satisfaction, and that we are exceedingly fortunate in retaining the services of Mr. Bull, our Manager and Secretary, and of Mr. Bailey, our engineer, and I hope, on behalf of the Board as well as myself, and I may add for you all too, that they may have long life and health to continue in your service and give their devotion to us as they have done in the past. I will now move—

"*That the Directors' report and statement of the accounts for the year ended December 31, 1895, with the appropriation of the reserve, depreciation and premium funds as shown therein, be and the same are hereby received and adopted.*"

Lord SUFFOLK seconded the resolution.

Mr. WALLER inquired if the authorities had yet given their sanction to the lighting of the lesser streets in the City, and whether the circular referred to by the Chairman would be issued every half-year, except when the annual report was issued.

Mr. GEORGE HERRING observed that the report was so good that it was unnecessary to say many words. From what they had heard respecting the applications coming in, he thought it would be fair to assume that during 1896 the Company would have about 60,000 more lamps connected than during 1895. Under these circumstances, and considering what a small extra outlay would be incurred in supplying current to these 60,000 additional lamps, he considered that they might reasonably calculate on earning a better dividend during the current year. He hoped, therefore, that the Chairman would see his way to slightly alter what he had said about paying an interim dividend. Could it not be put in this way : that if the progress of their business continued satisfactory and no unfortunate hitch took place in the earnings of the Company during the current half-year, the shareholders might look forward to an interim dividend, of whatever amount the Board might think fit, being paid at the end of the first half-year, and also a circular stating what progress had been made up to that time. He appreciated the force of the Chairman's remarks about the expense and trouble of making the accounts up twice. The shareholders did not want that to be done. They wanted a short statement as to the progress made by the Company, and what they would like as well or better was an interim dividend equal to 5 per cent. per annum.

The CHAIRMAN : In the first place, as regards the lighting of the minor streets. We are only too anxious to get the contract settled, and our engineer is in communication now with the City authorities on this matter. In answer to Mr. Herring, who has always taken a great interest in this Company, I may say that applications are still coming in for lights at about the same rate as in the past, which is a very extraordinary thing. They come in at the rate of 1,000 per week—sometimes slightly below the figure and sometimes above it. At Christmas and Whitsuntide, perhaps, the number drops for a week, but the applications continue to come in at a steady average, and that appears likely to go on for some time, although it cannot last for ever. With regard to the interim dividend this half-year, I may say it is of no use holding out the slightest hope of that. I am speaking honestly when I say I should be glad if we could promise it ; but experience of the past rather shows that we cannot pay a dividend in the first half of the year until the Company is longer established. I hope the returns may show differently, and if we are able to pay an interim dividend I shall be the first to move that it be done. I give my reason why I think an interim dividend should not be paid in the first half of the year. We were last year rated at a small amount, but this year our rating is really beginning to come into play, and the increased expense in this respect is something enormous. Then we have to make provision for paying the debenture interest and the dividend on the Preference stock and for depreciation. All these things, as a matter of prudence, have to be provided for out of the first half-year's working if you can manage it. Our rates now amount to about £5,000, but the amount will be increased to £6,000 or £7,000 next year. On the whole, therefore, we do not think it prudent to pay an interim dividend during the current year, unless the profits come in to a much larger extent than they have done in the past in the first half of the year. And at the second half of the year there will be the usual report and meeting. You already have the quarterly returns published, from which you can tell in a certain measure how the Company is going on. In the first half of last year, speaking roughly, we only earned enough to meet our outgoings, and the dividend on the Ordinary shares was practically earned in the second half of the year.

Mr. BOOTH thought they would be unwise as shareholders to force the hands of the Directors. If they had confidence in the Chairman and the Board let them be guided by their judgment.

The adoption of the report was then unanimously agreed to.

The CHAIRMAN next moved—

"*That dividends be declared as follows: 6s. per share on the Preference shares, making, with the interim dividend of 6s. per share paid on July 25th, 6 per cent. for the year ; 10s. per share on the Ordinary shares, being at the rate of 5 per cent. for the year.*"

Mr. F. W. REYNOLDS seconded, and it was agreed to.

The CHAIRMAN next moved the re-election of the Right Hon. Earl of Suffolk and Berkshire and Mr. Frederick W. Reynolds as Directors, which was carried.

Mr. WANCKE proposed and Mr. E. J. HARRIS seconded, the reappointment of the auditors (Messrs. W. H. Pannell and Co.) at a fee of 125 guineas per annum, and this was agreed to.

On the motion of Mr. HARRIS, seconded by Mr. HERRING, a vote of thanks was accorded to the Board and to the Chairman for the manner in which they had conducted the affairs of the Company during the past year, which the CHAIRMAN having acknowledged, the proceedings terminated.

Notting Hill Electric Lighting Company (Limited).

The ninth ordinary general meeting of this Company was held on Tuesday, February 25, 1896, at the Company's registered office, Bulmer-place, High-street, Notting-hill, Mr. Sidney Waters presiding, in the absence of Prof. Crookes, F.R.S. (Chairman of the Board).

The SECRETARY (Mr. R. G. Rawkins) read the notice convening the meeting.

The CHAIRMAN said: Ladies and gentlemen, in submitting the Directors' report and accounts, which I presume you will take as read, I have the pleasure to present to you a favourable account of the Company's progress. We propose to ask you to declare the full dividend at the rate of 6 per cent. upon the ordinary Preference shares, and a dividend of 2 per cent. for the whole year, or 4s. per share, upon the Ordinary shares, free of income tax, after placing £700 to the renewal and depreciation fund, and to continue the reduction of the preliminary expenses account by setting aside £151. 9s. 5d., or 3 per cent. of that amount. It has been the custom of the Chairman at previous meetings to refer to the accounts *seriatim*, and I think I cannot do better than to follow the same plan. The first to be considered is No. I. Account, "Statement of Share Capital :" The only change here is the issue of ordinary Preference shares, to which I will refer in dealing with the capital account. No. II., "Statement of Loan Capital :" This remains blank, the Company having neither debentures nor mortgages upon its property. No. III., "Capital Account:" I will first take the credit side, which deals with the capital receipts. Particulars are set forth here of the ordinary Preference shares just referred to. At the commencement of the year we allotted 450 of these shares, which had been previously applied for at par, and more recently 123 shares at £2 premium, in all 573 shares, of which 266 are fully paid up and 307 had £5 per share paid up at the end of the financial year. The improved position of the Company, and also the greater confidence felt in electric light undertakings generally as a medium for sound investments, enabled the Board to raise the price to the premium named. We have subsequently received applications for all the unissued shares at the same premium, and they will be allotted as further capital is required for our extensions. It is a matter for congratulation that the future of the Company is regarded with such confidence that we are able to issue these shares at a premium. The premiums already realised (£246) have been applied to the reduction of the preliminary expenses account, and the further amount (£2,276) which will be realised upon the issue of the remaining shares will be applied in the same manner, and when this is effected that account will be brought within comparatively small proportions and its liquidation will gradually proceed out of revenue. Upon the expenditure side of the account there are two items to notice : "To accumulators and connections at generating station," £1,818. 5s. 3d., and "to mains, including the cost of laying and construction," £2,489. 15s. 7d. With regard to the first item, it has been explained in the report that the expanding business of the Company necessitated an additional battery of accumulators. It has been built by the side of the original battery. I am glad to inform you that it is working very satisfactorily and quite up to our expectations, and if the shareholders care to inspect it we shall be very glad for them to do so at the close of the meeting. With regard to the item for mains, two-thirds of the outlay is for carrying our mains along Addison-road and extensions in its immediate neighbourhood, and the balance is for small extensions all over the system which are showing satisfactory indications of profitable business to the Company. It will be remembered that at one time we contemplated the erection of a second central station in the neighbourhood of Addison-road for the service of that district, but great doubts were felt whether the revenue likely to be derived from that part of the area would justify the outlay involved, and, moreover, a suitable site could not be obtained for the purpose. Under the advice of our engineer, the Directors made the experiment of supplying that neighbourhood from their central station, which is more than a mile distant. The result is a complete success, the concentration of our power under one roof and management proving very economical, while the supply of current to our customers is perfectly satisfactory. Our experience so far shows that our doubts as to a second station proving remunerative were entirely justified, as it is clear that it would not have paid its way for years. The total amount of capital called up you will notice during the year amounted to £4,195, which is about £1,500 less than the year's capital expenditure, and it has been found necessary to call up this £1,500 recently. We will now turn to No. IV. "Revenue Account," and upon the credit side you will notice a very satisfactory increase in the sale of current, 182,327 units having been sold, against 130,266 in 1894 ; this has been caused by the increased number of lamps connected, the total having risen from 15,669 in 1894 to 20,307 in 1895. Upon the debit side are the various items of expenditure, which with our greater output of necessity show some increase, but in most of the items the increase is small, with the exception of that for maintenance and renewal of the accumulators, while in some instances there is actually a reduction. With regard to the expenditure upon the

Digitized by Google

accumulators, the Board has thought it advisable to charge it entirely against revenue rather than take it out of the Depreciation and Renewal Fund, which has thus been left intact. I should like here to call attention to the low initial cost at which our current is produced, and by initial cost I mean expenditure in wages, coal and stores. The Directors propose to draw £400 for their fees for the past year, against £300 for 1894, and the remaining item on the account is the balance, which stands at £3,227. 14s 10d. and is carried into the net revenue account We now come to the No. V., "Net Revenue Account," in which 3 per cent. is written off the preliminary expenses, amounting to £151 9s. 5d. With regard to the item for interest, £39. 1s., I may explain that in some instances we have not felt justified in making extensions without a guarantee. The charge is for interest on these deposits, and it will be eliminated by the revenue derived from the extensions, which is gradually paying off the deposit and interest. £40 is written off on account of leasehold redemption, and £700 placed to the depreciation and renewal account, leaving a net balance of £2,329. 9s. available for distribution. No. VI., "Depreciation and Renewal Fund Account": This stands now at £1,300, and we are glad to be able to report that we have had no accident which has caused us to trench upon it. It is the policy of the Board to increase this fund to such a point that the Company shall be in a position to bear the strain of any breakdown to which, with all our care, it is obvious we are at any moment liable, without necessarily inflicting a loss of dividend upon the shareholders. An accident to a dynamo, or the breakdown of a boiler, from which we have so far been free, would make a serious inroad into this amount, and hence the Directors feel sure that a policy of prudence and foresight in the establishment of a substantial reserve will meet with your approval. No accident has occurred in the works during the year, and the only mischance that has happened of any kind was in the time of the great frost, when a number of the water companies' pipes burst in the roadways, and through this three of our longest culverts were flooded. Of course, we lost a good amount of current, but not one of onr customers was deprived of the light, and the pressure was kept up to its proper standard. We have since put in additional drains to mitigate the effects of such an occurrence in the future. The last account is No. VII., "General Balance Sheet," which is practically a summary of all the statements, and I think needs no further explanation. Having dealt with the accounts, I will now read to you the auditors' report. They state: "We beg to report that we have attended at Bulmer-place and checked the postings of the books for the three months ending December 31, 1895, and examined the vouchers for payments made and the invoices for goods purchased during that period. We have also inspected the share books of the Company and checked the transfers. We have prepared a list of the accounts in arrear at December 31, 1895, still outstanding at the date of this report, which amounts to £13. 4s. 4d. We beg to state that we found the books to have been correctly kept and all the vouchers, invoices and transfer deeds in good order. (Signed) Fox, Sissons and Co." I may state that this is a quarterly report, and that we receive a similar one every three months, and, of course, it is quite independent of the auditors' certificate, which appears at the foot of the accounts now submitted to you. In addition to Messrs. Fox, Sissons and Co.'s audit, I may mention that we have an entirely independent audit on behalf of the Board of Trade, which always confirms our own auditors' report in a most satisfactory manner. And now, having dealt with the past, I will, with your permission for a few minutes, look to the future. It is obvious that the business of the Company is increasing at a fairly satisfactory rate, considering that the neighbourhood is not one of the wealthiest in London, and that the houses in many parts are more or less scattered. This diagram, which Mr. Schultz has prepared, shows clearly the expansion of the output during the past four years. It is divided into months, and you will see how the amount of current supplied varies from month to month, and that the line representing each year's output always tops that of the preceding year. There is no reason why such expansion should not continue. In my opinion its rate will depend largely upon whether the improving condition of financial affairs which has undoubtedly begun continues to make progress, as I believe, in the absence of war or other disasters, it will do. People do not wire their houses if times are bad, but with returning prosperity and confidence, and with larger resources, they do not mind the necessary outlay. In addition to this there is a fair amount of new building either in progress or projected within our area, there are a large number of houses not yet lighted, and the use of electricity is increasing for other purposes, such as cooking; we have some of the utensils here to show you if you care to look at them afterwards; it is being used in various ingenious devices for advertising, and I hope soon, when the troublesome Act of Parliament which now stands in the way is repealed, it will be used for road carriages of all sorts. Another important field for our operations will, I hope, soon be available in the northern area as soon as we get the requisite powers; the Bill, which was delayed by the dissolution, is now before Parliament, and will, I believe, soon be passed. Then we shall proceed energetically to lay our mains in the streets we have undertaken, and what is very important we shall be able to carry a trunk line down the Holland Park-avenue (Uxbridge-road) and complete the Addison-road system from the Uxbridge-road, and thus being able to maintain our pressure by a complete circuit. Hence you will see that we have a fair prospect of increase of sales. On the other side we must look forward to some increased expenditure. Our expenses may be divided into two heads, one may be called the works cost or the initial cost of the current we produce, and the other the establishment charges. The works cost is bound to grow with our output, but the establishment charges will not increase at the same rate, and hence it is probable that our total expenses will not grow in anything like proportion to our sales. We may therefore, I think, look forward with confidence to a steady increase in our prosperity, our position being gradually strengthened as we proceed. Our lamp earning, and by that I mean the value of the current consumed by each lamp circuit, on our is still low. It is about 5s. 9d., which is slightly higher than last year, when it was 5s. 4d. It is probably lower than the other London companies, and this is partly due to the superior economy of our consumers, partly to our neighbourhood being lighter than other districts of London, and also to the fact that we have no public buildings such as clubs and theatres, and but few shops in our area. We must exercise great caution in taking such an important step as would be involved in a reduction of price, especially when it is remembered that our lamp earning is so very low. The character of our district must be considered. We have to make many extensions which only just pay their way, and I may mention that of 70 installations in 1894, 23 extensions were necessary, and last year 81 new installations required 23 extensions. We have at present a scheme of rebates which is based upon the value of current consumed by each lamp, which enables those who burn lamps for a great number of hours to obtain a slight reduction, and it is possible that in the future we may consider whether a further extension of this plan is practicable. Our customers may rely upon it that we shall study their interest as far as it is possible for us to do so, and that we recognise that it is the true policy of the Company, besides giving them a light which is perfectly steady, to consider what we can do to reduce its cost when we can do so with safety to the Company's progress. There remains little more for me to say, but I may mention that in view of fires at other electric light stations, besides revising our insurances, we have effected an insurance on our revenue in the event of such a disaster overtaking us. We have had our assessments for rating considerably increased; but, acting on the advice of Mr. J. P. Grolin, we decided not to proceed with the appeal upon this occasion. He then moved the adoption of the report and the declaration of the dividends.

Mr. A. E. FRANKLIN seconded the motion and said that their best thanks were due to Mr. Schultz for the successful manner in which the Company had progressed. Their Secretary also (Mr. R. G. Rawkins) had shown his great interest in the Company's welfare by the manner in which his work had been done. The Directors and shareholders tendered their thanks to the staff generally.

Prof. W. Crookes and Mr. Sydney Waters were re-elected Directors, the Auditors were re-appointed, and the proceedings terminated with a vote of thanks to the Chairman.

Charing Cross and Strand Electricity Supply Corporation (Limited).

The annual ordinary general meeting of shareholders of this Company was held at No. 2, Craig's-court, Charing Cross, on Monday, under the presidency of Mr. G. H. Brougham Glasier.

The GENERAL MANAGER and SECRETARY (Mr. E. Wilmot Seale) read the notice calling the meeting, and the report and accounts were taken as read.

The CHAIRMAN: I will now make a few remarks in connection with the business of the Corporation in the past year. First of all, if you make a comparison—as I daresay those of you who have been shareholders for some time would do—between the accounts we are now presenting and those which we submitted to you last year, you will find that the business has been a continually prospering one; that in all matters where it has been desirable to decrease the expenditure that has been done; that we have in many items been able to save very considerably; and that, as regards the output of the Company, it has been most satisfactory. You will find that the actual increase in the business is equal to 25 per cent. in the number of lamps supplied, and, taken in connection with the increase in the number of lamps supplied during 1894, the business has almost doubled itself in that respect in the period of two years. We have had very severe competition, the price per unit we are obtaining at the present time, as you are probably aware, having been reduced very considerably; but there is little doubt that the present price has commended itself very much to the consumers in the district we supply, and there is no doubt that that has had a good deal to do with extending and popularising electric lighting in our district. In connection with this matter I should just like to refer you to *The Electrician* of May 24th last, in which you will find, at page 127, a chart showing the pressure of the various companies in the metropolis taken on certain days by an eminent electrician. I am referring you to this particularly to show you what a very capital record we have—how regular our pressure is in comparison with that of other metropolitan companies. The pressure was taken in our case on May 6th of last year, and you will find it commenced with 100 volts and finished with 100 volts. The line is almost one continual straight one right through. It is an interesting diagram. You will note that some of the companies vary exceedingly, but that is not the case with us, and it is very satisfactory to the Directors to know that the pressure is so even all through. Of course, it might be said that this is one particular day; but as a matter of fact our records taken at several points on our district show, day by day and week by week, the same uniform pressure. That is a circumstance of very great importance in connection with electric lighting, because if the pressure varies considerably, you will find that your lamps will not stand the same time, and all sorts of unpleasantness arise. There is another thing which I must mention to you, and I have no doubt that you will be pleased to hear it. Notwithstanding the severe competition we have had to contend with, not a single customer has transferred his custom to either of our competitors. That is a very satisfactory matter for the Directors to know, and I have no doubt that it will be regarded as equally satisfactory by you. In No. 3 paragraph in our report we inform you that the station has been maintained in a high condition of efficiency. Looking at the accounts you will see that we have spent on repairs to machinery, &c., £1,517. This is a large sum, no doubt, but it is absolutely necessary that our machinery should be main-

Digitized by Google

tained in a very high state of efficiency, and it is also equally necessary that we should put by a fund to meet contingencies. You will find that we have done this already by carrying the sum of £3,000, out of this year's earnings, to depreciation account, which now stands at £5,300. We transfer the £3,000 to depreciation before we arrive at our net revenue. The next paragraph which I desire to allude to has reference to our Provisional Order. Most of you will be aware that we took power to apply some time back for a Provisional Order to supply a very much larger area, viz., the district of the Strand District Board of Works. In connection with that the Board of Trade granted us the Provisional Order for the district we wanted. Our Bill confirming this passed the House of Lords last year, but in consequence of the dissolution of Parliament we did not get it into the House of Commons, but this year we are going to start again at the point where we left off last year. I believe that our Bill will be in the House of Commons in about a fortnight, and you may rely upon it that we are only too anxious to get the Bill passed, and we have every hope that we shall succeed. We have had to meet rather strenuous opposition, which is still being maintained on the part of the Metropolitan Company. In connection with that matter I may mention rather a pleasing circumstance—namely, that petitions were presented to the Board of Trade and the House of Lords in support of granting us our Provisional Order, and the petitions were signed by no less than 850 of the principal owners of property and largest ratepayers in the district, among them being the lessees of the whole of the theatres, the editors and proprietors of the principal newspapers and printing works, &c. We now come to the fifth paragraph of the report. We want more room in order to be able to deal properly with the amount of electric energy we have to supply. An accident occurred last year to one of the companies which brought home very closely to us the disastrous position we might be placed in if any such thing had occurred to our Company—I refer to the fire that took place at one of the stations of the Metropolitan Company. We have secured premises in Commercial-road, Lambeth, occupying an area of nearly three-quarters of an acre, and we are now preparing for the formation of a large station there. The alterations are now being made, and the mains are laid connecting up this station, so that very shortly—in fact almost as soon as we can possibly get our machinery into position—we shall be able to connect up with and supply from our existing area and also the area we hope to obtain. The site of the new station is one which I think will commend itself to you. Commercial-road is on the other side of the river, a short distance from Waterloo Bridge, in the centre of wharf properties with large open spaces around. It is an admirable site for a station, and commended itself very strongly to the Managing Directors, who brought it before the rest of the Board, who were pleased to acquire so eligible a site. It has a river frontage, which is of great importance, because we shall be able to deliver our coals and other goods in connection with our business alongside. We therefore anticipate that we shall be able to considerably reduce our cost of production, besides effecting a considerable saving in freight That brings me to what is probably the most important point in connection with you, gentlemen, which, at any rate, it gives us the greatest pleasure to deal with—I allude to the net earnings. You find by the accounts that our net earnings for division amount to £12,587, after having written off, as I said before, £3,000 to depreciation account. After writing off £700 for preliminary expenses, £300 for law costs suspense account, after paying the debenture interest and the interim dividend for the last half-year, which was at the rate of 4 per cent., we are left with £5,424, which, added to the amount brought forward from last year, makes £5,729. This we propose to deal with as stated in the report, namely, to pay a dividend (less tax) at the rate of 6 per cent. for the half-year to December 31st last, making, with the interim dividend, 5 per cent. per annum for the whole year. This will absorb £4,350, and leave us the very respectable sum of £1,379 to carry forward to this year's trading, as against the £305 which we brought forward this year. Before I move the adoption of the report I will hear whether any gentleman has anything to ask in connection with the accounts.

Mr. T. P. LING inquired whether an estimate could be given with regard to the cost of erecting the new station referred to and laying out the works. He also desired to know whether it was proposed to add to the capital account.

Mr. WALLER asked whether it would not be possible to add in future a clause showing the percentage of generation and distribution expenses and renewals as compared with the earnings. This, he said, was done by some of the companies, and it was a great point to see how the expenses were diminishing.

The CHAIRMAN, in reply, said: In answer to the first question, it is impossible for us to tell you the amount we shall have to expend at the new station, as that is a matter which will entirely depend upon circumstances, owing to the position in which we stand with regard to the proposed increase in the area of our supply. You may, however, rely upon one thing—that the Directors will take care to keep the expenditure down to the lowest possible sum, having due regard to the efficiency and stability of the work. Of course we must increase our capital. That matter was decided at the special meeting we held some time in 1894. We have power to increase our capital, and this will be done in due course. This question, however, enables me to state one thing which I forgot to mention. We have arranged to borrow sums to the extent of £10,000, required in the erection of our new station, in sums as may from time to time be required, at 4 per cent., so that the capital which we shall want for the purpose of carrying out and completing the new station we shall receive as we require it, without having a large sum lying idle.

Mr. T. P. LING inquired if anything had been done yet with the view of converting the debentures from 5 per cent. to 4 per cent.

The CHAIRMAN: Nothing can be done at present in that direction. The debentures were issued for a certain time, but at the expiration of that period we shall no doubt pay off the existing debentures, and get the money we want for very considerably less than we are now paying. The present debentures will expire in 1900. In reference to the other question which was asked, I may tell you that the percentage of costs to revenue in 1894 was 50 per cent., but in the past year that has fallen to 45 per cent.

Mr. WALLER remarked that this was very satisfactory.

The CHAIRMAN: We shall be very pleased in next year's report to include something which will give you this information; but everywhere where we wanted to see an increase there has been an increase, and everywhere where we wanted to reduce the expenditure we have been able, through our engineers and our officers, to do so. The result is that our percentage of costs to revenue has dropped by 5 per cent. since 1894. He then proposed a resolution approving the report and accounts and the payment of the dividend therein recommended.

Mr. HILLHOUSE (a shareholder) seconded the resolution, which was carried unanimously.

On the motion of Sir HUGH MONTGOMERY, seconded by Mr. WALLER, the retiring Directors, Mr. Stefano Gatti and Mr. Richard Chadwick, were re-elected, and Messrs. O. R. Johnson and Son were re-appointed auditors, on the motion of Mr. LING, seconded by Mr. HILLHOUSE.

Votes of thanks were afterwards passed to the Chairman and Directors and the engineers and managers.

The CHAIRMAN: I beg to thank you for your vote of thanks to myself. The duties of the Chairman are probably the lightest of any officer in connection with the Company. We have two most excellent Managing Directors, whose interests are so bound up with the success of this Company that you may be perfectly sure nothing will be wanting on their part to achieve greater success than has been accomplished in the past. We have the greatest belief in the continued success of the Company, and nothing will be wanting on the part of my brother Directors and myself, or, I am sure, on the part of the officers of the Company, to achieve still greater success.

The CHIEF ENGINEER (Mr. W. H. Patchell) also replied, remarking that the success of the Company was attributable to the thorough unanimity with which the Directors, Managing Directors, General Manager, engineers and the staff worked with each other.

The proceedings then terminated.

Central London Railway Company.

The half-yearly ordinary general meeting of this Company was held on Wednesday, at the Cannon-street Hotel, Mr. Henry Tennant presiding.

The SECRETARY (Mr. R. O. Graham) read the notice convening the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN, having affixed the seal of the Company to the register of shareholders, said: Ladies and gentlemen, this is the first half-yearly meeting of the Central London Railway Company, and I may say that I and my colleagues are glad to meet you on this account, although, from the nature of the case, there is very little to speak upon, and very little to report. The undertaking in which you are interested, as shareholders, is not one of an ordinary character. I have no doubt you remember that its length is 6½ miles, and that it commences at Liverpool-street Station and ends at Shepherd's Bush, running by the Bank and under Oxford-street to its destination. It is, as you will probably recollect, to be constructed by means of two separate tunnels from end to end. Of course these tunnels, when completed, will be adequately lighted. There are to be 14 stations on the 6½ miles of railway, and these will be placed in such positions as will be most likely to gather up the largest amount of traffic; and you will also remember this other interesting fact—that it is to be worked by means of electricity. A contract was entered into with the Electric Traction Company—a contract which embraces the acquisition of land and property, the payment of compensation, the construction of stations and other works, the provision of rolling stock, and all the machinery for generating the motive power. In short, the Traction Company by the contract are to deliver over the railway and all its adjuncts in a complete state. The report and accounts presented show that the sum of £506,420 has been received on account of the shares issued, and there has been expended a sum of £168,265. The principal item of the expenditure, £115,026, is entered under the head of payment on account to the contractors, and that represents the sum for parliamentary deposit. This shows as a payment under the constructed contract, because the contractors are responsible to the Company for it, they having taken upon themselves the obligation of seeing that that money is returned when the line is completed. The other item, £44,000, is for the parliamentary and preliminary charges. It is provided by the Act of 1894 that interest at the rate of 3 per cent. may be paid on the called-up capital, and that, during the last half-year, has been done and appears in the accounts. Now, if you turn to statement No. 1, you will there find that the total capital powers of the Company amount to £3,800,000; but, as regards the amount to be raised by loan, that is subject to a small reduction, which may extend, perhaps, to about £50,000, under the provisions of the Act of 1894, which relate to the payment of interest. The share capital authorised by Parliament amounts, as you will see, to £2,850,000; and in reference to statement No. 2 it will be observed that the unissued shares have been subscribed for under an agreement by the Electric Traction Company, and that Company has become liable for the sums subscribed. The unissued shares to which I have referred amount to £682,470, and the share capital to £2,850,000. Now, further expenditure on capital account is roughly estimated at £3,380,000, which, added to the expenditure already incurred, brings up the amount to £3,550,000. The authorised capital powers amount to £3,800,000, so that we have a margin of £200,000.

Digitized by Google

left for contingencies, which, however, I may say, from anything which I have hitherto seen, are not likely to arise. We can none of us tell beforehand what may happen. We can only speak of circumstances as they exist and as they present themselves to one's mind in looking over the whole of the facts of the case. I may now, perhaps, make a general observation upon the course which it has been found necessary to take after it was decided to proceed with the construction of the Central London Railway. The prospectus was issued at the end of June last. Now you all know that the Central London undertaking is not, as I have said, of an ordinary character. In its execution you cannot break ground just where you like. You cannot go and say "this is a convenient place in this street or that street for making a hole with a view of beginning with the Central Railway." We are necessarily limited to certain points where work may be commenced, as the interests of so many people and authorities are touched by a work of this magnitude. Much negotiation is necessary, and a great deal of work of a parliamentary character has to be undertaken. I notice in the several Acts of Parliament that the Central London Company have that there are more than 50 individuals or public authorities of one kind or another whose interests are specifically protected in some way or another. Therefore, one of the first steps necessary was to enter into communication with the public authorities whose sanction to the plans was required before the works were proceeded with. Proceedings of this kind you all know take time, and when we bear in mind that those public authorities have duties and responsibilities cast upon them which they are expected to exercise and fulfil in the interests of the public generally, it is not a matter of surprise that those public bodies should themselves require a considerable amount of time in order to enable them to mature their views. Now, although a considerable period has been thus occupied, we do not think that the Railway Company, on the whole, has just ground of complaint. The London County Council, the Commissioners of Sewers, and other bodies have, we believe, looked upon the Central London Railway with a favourable eye as an undertaking calculated greatly to promote the public interest and advantage, and have, on the whole, been disposed to act accordingly. We have certain points at which stations are to be erected, and it is from these points that the work of tunnelling must be commenced and carried on, and here arises the important question of the acquisition of property all along the line. Without delay notice was given to those parties whose property was affected, but as business men we all know that we cannot if we would turn out occupiers without due notice, nor can we take possession without a good deal of negotiation as to the precise allowance for compensation, and in many cases arbitration has to be resorted to. A good many purchases have been made, and the subject is receiving every possible attention. The facts I have mentioned will show that where so much preliminary work has to be done the actual work of construction is necessarily delayed. But I am glad to say that as regards the Mansion House station and subways—a work of great magnitude and of a very intricate character—the plans have been approved by the City authorities, and the contractors will before long make a commencement at that point. I may also say that tenders have been invited by the Electric Traction Company for the construction of the tunnels for nearly the whole line. The Waterloo and City Electric Railway, whose terminus is at the end of Queen Victoria-street, have also entered into an arrangement for the use by them of the subways at the Mansion House, which the Central London Company have to construct, and we are satisfied that the arrangement is a good one, the Waterloo Company paying a part of the cost, and we think it will result in benefit to both companies. After a few more observations he concluded by moving the adoption of the report and accounts.

Lord COLVILLE, K.T., seconded the motion.

The CHAIRMAN, in reply to Mr. Griffiths, observed that no Director of the Central London Railway Company was on the Board of the Electric Traction Company, or had any financial interest in the latter. He believed that a great deal of the money they had in hand would before long be paid away to the contractors. If they were to get the whole of their line speedily executed he believed they must begin with it at a number of different points in its course. The parliamentary expenses were heavy, but unavoidable, inasmuch as they had had to get three distinct Acts of Parliament.

The motion was carried unanimously.

The retiring Directors (Sir Francis Knollys and the Hon. Algernon H. Mills) were re-elected.

One of the auditors (Mr. Pannell) was also re-appointed.

The meeting was thereafter made extraordinary, and a resolution, moved by the CHAIRMAN and seconded by the Hon. ALGERNON H. MILLS, authorising the raising of £150,000 additional Ordinary capital by the issue of 15,000 new shares of £10 each, in pursuance of 55 and 56 Vict., cap. 241, was unanimously agreed to, and the proceedings ended with a vote of thanks to the Chairman.

Tramways Union Company (Limited).

At the meeting of this Company on Tuesday, Mr. E. M. Underdown, Q.C. (the Chairman of the Company), said the Directors still adhered to their views as to the importance of substituting electric traction for horse traction in connection with two of their undertakings. Not only did they believe that the maintenance of their present profits depended upon this course being adopted, but that those profits would be very largely increased by the introduction of electric traction. In all countries where you have to carry the inhabitants of large towns you must after a time reduce the fares in order to meet the requirements of, he would not say the lower classes, but of those people who do not feel inclined to pay high charges for being carried about, and therefore it is, under such circumstances, important to carry these people as often as possible so as to keep up your takings per mile. That cannot be done to the full extent by means of horse traction. By means of electric traction, however, they could carry more people in the cars and travel at an increased speed, and what was, perhaps, the most important consideration of all, at different periods of the day, when the traffic pressed most, they could convey large numbers of people to and from particular points in a manner which was impossible with horse traction without keeping a very large and disproportionate stock. Their negotiations for the introduction of this power had been carried on quite satisfactorily in the two cities with which they proposed to deal—Bremen and Madrid. At Bremen the matter had been for some time before the Council of the city, and they were asking for a considerable extension of the period of their concession. The introduction of electric traction would involve an expediture in respect of fixed appliances, and it was necessary that they should have a sufficient time to amortise or get back the outlay they would have to make on these appliances. That part of the bargain had been approved by the Council. The present position of things therefore improved the capital value of this part of their undertaking. With regard to Madrid matters were very much in the same position, although they had not reached a stage quite so advanced. It seemed to be the desire of the public in Spain, as elsewhere, that electric traction should be introduced. He then moved that a dividend at the rate of 5 per cent. for the year be paid.—Mr. George Richardson seconded, and said he believed that by the introduction of electric traction better results than ever would be obtained from their undertakings.

North Staffordshire Tramways Company (Limited).

The ordinary general meeting of this Company was held on Tuesday at the Guildhall Tavern, Gresham-street, E.C. After the report and accounts had been adopted, the Chairman (Mr. W. J. Carruthers-Wain) moved:—"That the Directors be requested to proceed with the pending negotiations with the various local authorities for the adoption of electricity as a motive power instead of steam, and that the agreement with the British Electric Traction (Pioneer) Company (dated January 8, 1896) be approved, and that the Directors be, and hereby are, requested to carry the same into effect." He said that when the Board of Trade inspector, early last year, inspected their lines with a view to the renewal of the permission to use steam power, he found that a considerable amount of renewals was necessary, and he also discovered a strong feeling in favour of the adoption of an improved system of traction. The local authorities through whose districts their lines passed were also in favour of considerable extensions of their present system. If these lines were to be worked by steam there was no possible method of raising the necessary capital, and consequently the question of the adoption of a system of electric traction had to be considered, and the Directors had now prepared a very comprehensive scheme. By order of the Board of Trade they were compelled to relay a good portion of their existing line within two years, and they would have to find the necessary money for that purpose. A well-known company had, however, entered into an agreement with them to find the necessary capital for relaying the remainder of their line, to equip the line electrically from end to end, and to provide the necessary generating plant and do everything else necessary for working the line electrically. The Company's present lease was not a long one, but if they agreed to equip it electrically they would get an extension of about 15 years. If the shareholders considered, however, what they had been able to do with the limited means at their command, he was sure they would unhesitatingly agree to the adoption of the Directors' suggestions for working the line by electricity, and he was confident that that consent would improve the position of the Ordinary shareholders. In answer to a question, the Chairman said the proposed extensions would be made by an entirely independent company, but they would act as considerable feeders to their lines. After the electrical contract came into operation these extensions would be worked by the Company at a rate which would give them a profit. The resolution was then passed unanimously.

Telegraph Construction and Maintenance Company (Limited).

The annual report of the Directors of this Company will be submitted to the members at the thirty-second ordinary meeting, to be held at the offices, 38, Old Broad-street, E.C., on Tuesday next, March 3rd, at one o'clock:—

The report states that the accounts for the past year show a net profit of £32,589. 14s. 1d., after charging interest on debentures; £53,509. 18s. 5d. is brought forward from last year, making a total of £86.099. 12s. 6d. From this is deducted the interim dividend of 5 per cent., paid in July last, amounting to £22,410, leaving £63,689. 12s. 6d. to be dealt with. Of this sum the Directors propose to distribute a dividend of £1. 4s. per share, absorbing £44,820, being at the rate of 10 per cent., and making, with the amount already paid, a total dividend for the year of £1. 16s. per per share, or 15 per cent., free of income tax, leaving £18,869. 12s. 6d. to be carried forward to the next account.

Various lengths of telegraph cables have been manufactured for different cable companies, and for foreign and colonial Governments, including 705 knots for the Government of Japan. Repairs of the Greetseil-Valentia and Hoyer-Arendal cables have been successfully carried out for the German Government. The factories at East Greenwich and Wharf-road and the Company's steamships are in good and efficient condition.

Mr. James Pender, M.P., and Sir Robert G. W. Herbert offer themselves for re-election as Directors, and the auditors, Mr. John Gane (of the firm of Messrs. Gane, Jackson and Jefferys), and Mr. Patrick A. Glegg (of the firm of Messrs. Welton, Jones and Co.), also seek re-election.

Digitized by Google

Chelsea Electricity Supply Company (Limited).

The following is the Directors' report, to be presented to the annual ordinary general meeting to be held at the central station, 19, Cadogan-gardens, on Wednesday next, at 12 o'clock :—

During the year an issue has been made of £60,000 Four and a-Half per Cent. Debenture Stock, which was fully subscribed, and the balance of the Ordinary shares authorised has also been allotted and fully paid up. The original Six per Cent. Debentures (£36,900) have been redeemed. A Stock Exchange quotation has been granted for both the Debenture stock and Ordinary shares. The balance of the premiums on these issues (including payment of premium due on the redemption of Six per Cent. Debentures) amounts to £5,798. 8s. This balance has been dealt with as follows :—Renewals and depreciation fund, £1,500; special law and incidental expenses written off, £3,251. 1s. 5d.; reserve fund, £1,047 6s. 7d. The item, £3,251. 1s. 5d., is special capital expenditure, and has been necessitated by legal proceedings in connection with the Cadogan-gardens station. The net revenue for the year (apart from the premiums), after payment of debenture interest (£3,143. 16s. 3d.), is £6,414. 16s. 5d. Of this, £900 has been paid as interim dividend at the rate of 6 per cent. per annum on the Preference shares for the half-year to June 30th last, and the Directors recommend that the balance of £5,514. 16s. 5d. shall be applied as follows :—6 per cent. per annum on the Preference shares for the past half-year (£900); 5 per cent. per annum on the Ordinary shares for the year (£3,500); carried forward, £1,114. 16s. 5d.

The price charged for current was reduced on July 1st from 8d. to 6d. per unit. The number of lamps supplied on December 31st last was 57,354, an addition of 10,068 during 1895, an increase of upwards of 50 per cent. on the number added in 1894.

A considerable part of the capital expenditure has been incurred in extending the mains and enlarging the Cheyne Walk station, in order to meet the increasing demand for current. An advantageous purchase has also been made of the freehold of a large plot of land around and including Cheyne Walk station, in view of the necessity for providing increased accommodation for the Company's works.

Mr. Nugent Daniell and Mr. E. Garcke offer themselves for re-election as Directors, as also do the auditors, Messrs. Cooper Bros. and Co.

Isle of Man Tramways and Electric Power Company (Limited).

The report of the Directors of this Company states that the sum available for dividend, after providing for debenture interest, amounts to £13,240. 1s. 6d. Interim dividends on the Preference and Ordinary shares for the first six months of the year, at the rate of 6 per cent. and 7½ per cent. per annum respectively, amounting to £4,312. 10s., have already been paid, and the Directors now recommend that dividends for the remainder of the year at the same rate (amouting to £4,687. 10s.) be declared, that £2,000 be added to the reserve and renewal fund, and £2,240. 1s. 6d. be carried forward. The traffic upon the electrical section of the line has been very satisfactory, and the Directors contemplate ordering more motor cars to cope with the enormous and increasing traffic. The Directors state that they have arranged for the purchase of the site of the junction of the electric and horse car lines for the erection of a suitable power station. They have secured a further 21 years' lease from 1897 of the Douglas Bay line from the Town Commissioners, also power to double the entire line, and to construct and work a cable tram line to Upper Douglas, which has been commenced. Preliminary arrangements have been made for the purchase of the Snaefell Mountain Railway for £72,500, which the Directors think will prove highly advantageous to the Company. The capital required for the construction of the upper town tramway and for the purchase of Snaefell Mountain Railway will be obtained by the issue of debenture stock.

Liverpool Electric Supply Company (Limited).

The Directors' report for the year ended December 31st last refers to the sale of the Company's business to the Corporation, and to the interruption of the progress of the Bill in Parliament caused by the late Dissolution. The Bill had passed some of the stages in the House of Commons, but was suspended until the present Session. The Directors anticipate that it will receive the Royal assent before Easter, after which the sale will be completed. One of the conditions of the arrangement with the Corporation was that the Company should be entitled to declare and pay dividends at the rate of 6 per cent. per annum from January 1, 1895, till the completion of the purchase. An interim dividend at this rate was paid for the half-year ended June 30th last, and it is now proposed to pay a dividend at the same rate for the second half-year of 1895.

Scarborough Electric Supply Company (Limited).

The report of the Directors states that during the past year the Company continued to make satisfactory progress. The equivalent of 2,285 8-c.p. lamps was added to the Company's mains during the year. The number of customers is now 235, and an equivalent of 12,788 8 c.p. lamps are connected. Since the last report 571 yards of additional mains have been laid, bringing the total up to 13,263. The capacity of the mains and the number and capacity of the transformers have also been increased. To meet the increased demand, an additional boiler and two additional sets of engines, dynamo and condenser (one of 150 H.P. and one of 100 H.P.) have been put in, and are now working very satisfactorily. During the past year 141,101 units of electrical energy had been supplied to customers, and the gross revenue, including meter rent, amounted to £3,613. 19s. 3d. After deducting the expenses, there remains a balance of £937. 9s. 8½d., which was more than twice the profit made in 1894. Adding the balance of £418. 12s. 3d. brought forward from the previous year, there was a sum of £1,356 available for distribution, and the Directors recommend that this should be applied in paying a dividend of 2½ per cent. (which will absorb £772. 13s.), and in writing off the sum of £304. 16s. 0½d. from the preliminary expenses, leaving a balance of £278. 12s. 11d. to be carried forward. The retiring Directors are Messrs. J. E. Ellis, M.P., and Gilbert Wilkinson, and being eligible they offer themselves for re-election, as does the auditor, Mr. C. E. Bradley.

MEMORANDA.—Bank rate, 2 per cent. (Feb. 22, 1894). Price of silver, 31 7/16d. per oz. (Feb. 27th). Consols (2¾ per cent.) 109 3/16—109 7/16 for money, 109 3/8—109 5/8 for account; 2½ per cent. 105½—105¾ (Feb. 27th). Stock Exchange Settling Days: Consols, March 2nd; Stocks and Shares Continuation Day, March 10th; Ticket Day, March 11th; Pay Day, March 12th; Mining Share Carry-over Day, March 9th.

BRITISH SOUTH AFRICA COMPANY (LIMITED).—The report of the Directors of this Company to March 31, 1895, contains interesting information regarding the progress made in the Company's land line telegraphs, which is stated to have worked successfully during the year, no complete interruption of communication of any moment having occurred. The work done included the completion of a new wood pole line between Buluwayo and Charter. This route follows the main line of development. A branch line from Gwelo to the Selukwe Mining District has been authorised, and is near completion. An iron pole line between Mangwe and Macloutsie (96 miles) has been completed, and Macloutsie has become the transmitting station for the Company's system, in place of Palapye. The Company has also, under contract with the Beira Railway Company, the telegraph line from Chimoio to Salisbury. This line was made available to the public on September 16th, and in conjunction with the Railway Company's wire to Beira, affords communication between Salisbury and its seaport. The total length of telegraphic line now in operation under the control of the British South Africa Company, south of the Zambesi, is 1,354 miles. The traffic receipts during the year were £9,701, expenditure £6,432. For the six months ended September 30th the receipts approximated £7,632, expenditure £3,390. It has been decided by the Directors to materially improve the pay and status of the officers. With regard to the construction of the Salisbury-Tete section of the Transcontinental Telegraph Company's line, previous anticipations have not been realised, although temporary through connection was made with Tete on October 22nd last, and communication has been fairly well maintained since that date. One hundred and sixty-two miles of permanent and 75 miles temporary lines have been erected. An office at Mazoe, on this section, was opened on September 24th. Since communication was established with Tete it has been maintained by joining the completed portion of the line from Salisbury to the Portuguese wire, which runs in a southerly direction from Tete, by means of a temporary line 62 miles in length. Originally it was arranged that there should be no public telegraph office of the Company within Portuguese territory, but the local Portuguese authorities requested that temporary arrangements should be made for the acceptance of telegrams at their local office at Tete. This placed Tete in telegraphic communication with Delegoa Bay, Mozambique, and the outer world generally. The report states that the importance to the Portuguese Government of the establishment of a permanent office at Tete, from an administrative point of view, and also on commercial grounds, is so great, that it may eventually be found to the advantage of all concerned that a modification of the original stipulation should be made. The Portuguese Government has erected a telegraph line from Chinde to Tete, and that by using the Trans-continental line, which runs through the latter place, the important shipping community of Chinde (the seaport of Northern Rhodesia and the Nyassaland Protectorate) is brought into touch with other parts of Central and Southern Africa, as well as with the rest of the world. Communication has been recently established between Salisbury and Blantyre. For the extension north of Blantyre, 200 miles of material was shipped from the Clyde in June last. A working agreement has been entered into between the African Trans-continental Telegraph Company and the British South Africa Company with regard to telegraph rates, which is described as mutually satisfactory, and follows the general lines of the South African Telegraph Union. The year's telegraph receipts to March 31, 1895, were £3,268. 16s. 7d., against £370. 7s. 6d. to March, 1894.

DOUGLAS SOUTHERN ELECTRIC TRAMWAYS (LIMITED).—The statutory meeting of this Company was held at Manchester last week. The Chairman (Sir J. S. Goldie-Taubman) said the permanent way would be completed by the middle of March, and work in connection with the power station had been commenced. The cars were also in hand, as was also the electrical equipment, and the Directors were well satisfied with the progress that had been already made.

HOVE ELECTRIC LIGHTING COMPANY (LIMITED).—The Directors' report states that the profit for the year amounted to £2,562, compared with £1,243 for the preceding twelve months. The Company has at present an equivalent of 18,403 8 c.p. lamps. The revenue from the sale of current increased from £3,617 in 1894 to £5,343. After adding £15 brought forward, and deducting £1,038 for interest on loans and debentures, a balance of £1,539 remains to the credit of the net revenue account. The Directors propose to write off £134 from the preliminary expenses account, to place £200 to reserve, and to declare a dividend at the rate of 4 per cent. per annum on the share capital, carrying forward £132. The number of shares issued to date is 6,260, and the Directors now offer the balance of 1,740 shares to the present shareholders for subscription, at £5. 5s. per £5 share. The Directors notify that they intend to pay off the £12,500 Five per Cent. Debentures on July 1 next, and offer debentures bearing 4 per cent. interest in exchange, which holders of £7,250 of the old debentures have agreed to accept.

NEW COMPANIES, STATUTORY RETURNS, &c.

LARNE ELECTRIC LIGHT WORKS (LIMITED).—This Company was registered on February 24th, with a nominal capital of £4,000 in £1 shares (including 500 Five per Cent. Cumulative Preference), to acquire the business of electric lighting contractors lately carried on by J. E. H. Gordon and Co. (Limited) at Larne, Ireland, together with the goodwill, leasehold premises, plant, machinery, capital, contracts, patent rights, property and effects of the said business, including the sum of £100 held by the Larne Town Commissioners as a deposit in accordance with the agreement of July 6, 1894, made between the Commissioners and J. E. H. Gordon and Co., Limited (by D. A. Norris, C.A., Suffolk House, London, E.C., their receiver and manager), and also the three-quarter interest in British Patents Nos. 8,638 and 17,855 (1892) and United States Patent No. 487,356 (1892), and to carry on the business of electrical engineers and suppliers of electricity. The first subscribers, with one share each, are: J. D. A. Norris, chartered accountant, A. H. Tucker, R. H. M. Hill, A. F. Leatherbarrow, W. J. Rivington, R. H. Milward and C. Piper. The first Directors are J. Rivington and J. D. A. Norris.

NORTHWICH ELECTRIC SUPPLY COMPANY (LIMITED.)—This Company was registered on February 24th with a nominal capital of £10,000, in £5 shares, to carry on the business of supplying electricity for lighting, heating and motive power purposes to public and private consumers in the Urban District of Northwich (Chester), the townships of Leftwich, Davenham and Hartford, and such other places as the Company may from time to time determine. The first subscribers, with one share each, are: T. Ward, J.P., R. J. Browne, T. Corry, J. Burgess, N. P. F. Sandford and W. M. Beckett and Edward T. Ward, civil engineers.

L. ALWYN (LIMITED).—The annual return to February 14th has been filed. Out of a nominal capital of £2,000, in £1 shares, 1,521 shares have been taken up, and 507 have been issued as fully paid. The full amount has been paid on 1,014 shares.

HOLOPHANE (LIMITED).—This Company was registered on February 19th with a nominal capital of £100,000, in £1 shares, to carry into effect an agreement for the acquisition of certain patent rights for the construction of Holophane glass globes, and the benefit in any other country (except the United States or France) of all improvements in the said patented inventions, and to carry on the business of manufacturers of and dealers in Holophane glass globes, &c.

INCANDESCENT ELECTRIC LAMP COMPANY (LIMITED).—The annual return to December 27th has recently been filed. The nominal capital is £25,000, in 2,000 Ordinary and 500 Deferred shares of £10 each. 1,200 of the former and 100 of the latter class have been taken up; all the Deferred have been issued as fully paid, and a call of £9 10s. per share has been made on the Ordinary shares.

INRIG AND CHESTER (LIMITED).—This Company was registered on February 21st, with a capital of £2,000, in £1 shares, to acquire and take over as a going concern the business of an electrical and general engineer now carried on at 44 and 46, White Post-lane, Victoria Park, London, and elsewhere, under the style of "The Globe Electrical Company," to carry into effect an agreement made with Alec. G. Inrig, and to carry on the business of electrical engineers, manufacturers of and dealers in electrical plant and fittings, mechanical and general engineers, machinists, &c. The subscribers are: Alec. G. Inrig, electrical engineer (500 shares), and R. Jenkins, J. F. Shallis, Alexander Shanks, engineer, G. C. Murray, electrician, E. W. Athill and A. Chester, electrical engineer (one share each). The first Directors are Alec. G. Inrig and A. Chester.

ISLE OF WIGHT ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return to November 14th has been filed. The capital is £1,000, in £1 shares. Seven shares have been subscribed for, but no calls have been made.

ITALIAN ELECTRICAL LIGHT AND POWER COMPANY (LIMITED).—The annual return to November 27th has been filed. Out of a capital of £60,000, in £4 shares, 307 shares have been taken up, 300 have been issued as fully paid, but no calls have as yet been made on the remainder.

JULIUS SAX AND CO. (LIMITED).—The annual return to December 28th has been filed. The whole capital of £20,000, in £10 shares, has been taken up, and 1,993 have been issued as fully paid. No calls have been made on the remaining seven shares.

LAMINA ACCUMULATOR (ELIESON'S BRITISH PATENTS) SYNDICATE (LIMITED).—The annual return to January 3rd has been filed. Out of a capital of £12,000, in £1 shares, 10,007 have been taken up, and 6,250 have been issued as fully paid. A call of 15s. per share has been made on 3,757 shares.

LAURENCE, SCOTT AND CO. (LIMITED)—The annual return to January 14th has been filed. The capital is £30,000, in £10 shares. 1,407 of these have been taken up, and 500 have been issued as fully paid. £10 per share has been called on the remaining 907 shares.

CITY NOTES.

BRISTOL TRAMWAYS AND CARRIAGE COMPANY (LIMITED).—The half-yearly meeting of the shareholders of this Company was held at the Grand Hotel, Bristol, on Tuesday, Mr. W. Butler presiding. He said they had reason to consider the present aspect of the Company's affairs as most encouraging. With reference to further extensions of their electric traction system, although the Electric Lighting Committee of the Town Council suggested that they should take current from the Corporation mains for all future extensions, the Sanitary Committee had made no stipulation to that effect. If the Corporation seriously meant to impose such a condition on the Company the Directors would make no further attempt to extend their electric traction system. The production of the motive power was one of the most vital parts of the Company's working, for which the Directors were responsible to the public, and they would not undertake that responsibility unless they had full control of the management of their own undertaking.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended February 23rd were £968, against £949 in the corresponding week of 1895, an increase of £19. The total receipts for the half year amount to £7,914, against £7,988 in the corresponding period of 1895, a decrease of £74.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—Warrants for the dividends on the Preference and Ordinary shares of this Company have been posted.

GENERAL HYDRAULIC POWER COMPANY (LIMITED).—At the general meeting of this Company on Tuesday last the Chairman (Mr. H. Chapman) stated that the use of hydraulic power for producing current for electric lighting had advanced a stage during the year. Their supply was now actually being used in the City and West End for this purpose, and there might be further use for the power in this direction. Electricity was often referred to as being a serious competitor with hydraulic power, but for the special purposes for which their supply was mainly used the competition was not so severe.

W. T. HENLEY'S TELEGRAPH WORKS COMPANY (LIMITED).—The Directors of this Company propose, subject to audit, to pay a dividend of 5 per cent. upon the Ordinary shares of the Company for the year ended December 31, 1895, making, with the 3 per cent. interim dividend already paid, 8 per cent. for the year.

HOUSE-TO-HOUSE ELECTRIC SUPPLY COMPANY (LIMITED).—In our last issue, on p. 567, at the conclusion of the Chairman's opening remarks a sum of £1,800 is given as that spent by the Company during the past financial year in the purchase of additional plant, &c. The amount should have been given as £18,000, not £1,800.

IMPROVED ELECTRIC GLOW LAMP SYNDICATE (LIMITED).—A private meeting of the members of this Syndicate was held at the Cannon-street Hotel on Wednesday.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended February 23rd amounted to £1,059. The amount for the corresponding week last year was £847. Increase £212.

LONDON PLATINO-BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The half-yearly coupons, which fall due on March 2nd, of the £100,000 Six per Cent. Debentures of this Company will be paid by Messrs. Glyn, Mills, Currie and Co., 67, Lombard-street, London, E.C., on and after that date. Coupons must be left three clear days for examination.

MAGDEBURG TRAMWAYS COMPANY (LIMITED).—An extraordinary general meeting of this Company was held last week at Birmingham, to sanction the sale of the Company's undertaking to the Union Elektricitäts-Gesellschaft of Berlin, on the terms of two agreements, dated May 27th and December 13th last. According to the terms of these agreements the amount of the purchase-money was £86,000, but the sale was to be subject to the consent of the Town Council of Magdeburg to the transfer of the concessions and other conditions. After deducting the debenture debt (£25,000) and other sums, there would be £52,700 left for distribution. The Chairman (Major Fosbery), in proposing the resolution approving of the sale, gave a history of the undertaking from its formation in 1886, and ascribed their position to over-capitalisation and mismanagement in the early stages of the undertaking. The result of the sale would be that the shareholders would receive about £5. 10s. for each £10 share, and that was the best bargain the Directors could make. The resolution was seconded by Mr. A. Lloyd, and was duly carried.

NATIONAL ELECTRIC SUPPLY COMPANY (LIMITED).—The annual meeting of the shareholders of this Company was held at the offices, 119A, Fishergate, Preston, last week, Mr. E. H. Booth presiding. The Chairman, in moving the adoption of the report and accounts, congratulated the shareholders on the past year's working. Although the Directors were not in a position to declare a dividend, yet they had made considerable progress. In 1893 their income was £3,345, and their expenditure £4,354; in 1894 the figures were £4,778 and £3,783; and for 1895 their income was £5,739 and expenditure £3,339, a reduction in expenses of £1,016 compared with 1893, and a profit of £2,401. The Chairman then referred to the fact that the Town Council had decided to light most of the public thoroughfares and streets of the town electrically. The Church of the English Martyrs had been fitted up for the electric light, and altogether there were indications of a progressive value in the property of the Company. He anticipated that they would be able to declare a substantial dividend next year. The report was unanimously adopted.

PORTSMOUTH STREET TRAMWAYS COMPANY (LIMITED).—A special meeting of this Company will be held at 7, Poultry, E.C., on Friday, March 13th, for the purpose of considering the Company's proposed Bill in Parliament seeking powers to introduce electric traction on their lines, and to enter into an agreement with the Portsmouth Corporation for the supply of the necessary electric current.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee have appointed Wednesday, March 11, a special settling day for 250,000 fully-paid Preference shares of the Sulphide Corporation (Ashcroft's process), Limited, and 40,007 fully-paid shares and 29,993 shares (10s. paid) of the Westralian Electric Lighting and Supply Company (Limited). Application has been made to the Committee to allow the Ordinary shares of Sir W. G. Armstrong, Mitchell and Co., Limited (Nos. 1 to 3,000,000), to be quoted in lieu of the Ordinary Stock of the old company now quoted.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended February 21st, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,384.

THE ELECTRICIAN

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861—1878.

No. 929. [Vol. XXXVI. No. 19.] FRIDAY, MARCH 6, 1896. PRICE SIXPENCE.

NOTES.

AFTER a discussion lasting nearly six hours, the House of Commons on Monday evening last agreed, without a division, to the second reading of Mr. RITCHIE's Light Railways Bill. This Bill, as is generally known, differs from the one introduced last year by Mr. BRYCE, in that it contemplates State loans in aid; and it was this new departure which was subjected on Monday evening to a vigorous but unavailing onslaught. We agree with the President of the Board of Trade in thinking that light railways "may do *something* to improve the agricultural industry," but we also agree with the member for the Spen Valley division of Yorkshire that the real root of the depression of our farming industry lies beyond the reach of this particular parliamentary palliative. However, since a few millions are apparently about to be spent upon some sort of mechanical traction in rural districts, the many merits of electric traction should ensure a copious flow of orders in the direction of the electrical industry, and enable the makers of motors, railway generators, and car-gearing to regard the economic heterodoxy of the proceeding with the equanimity begotten of a well-filled order-book.

To all water-power and day-load enthusiasts we would commend a careful perusal of Mr. RUTHVEN-MURRAY's report to the Electricity Committee of the Worcester Corporation, which will be found in another column. At the time when it was decided that Worcester must have a municipal electric supply, there was, of course, the usual clamour for the utilisation of the flow of a local rivulet. The idea received the genial benediction of the advisory engineer, although it involved placing the generators some three miles away from their work. With "power for nothing" and municipal management, only a day-load was wanting to ensure complete success. A day-load lay ready to hand in the shape of the pumping work at the municipal waterworks, and this was accordingly gladly undertaken by the Electricity Committee. It is, perhaps, unnecessary to remark that we have no prejudice against water-power or day-loads. What we do contend, and we think the experience at Worcester is a case in point, is that water-power schemes in this country are not, as a rule, likely to prove economical, and that day-load does not of necessity spell profit.

TAKING the past year's figures, Mr. MURRAY finds that the total cost of the Board of Trade unit, exclusive of the charges for interest and sinking fund, comes out at 2·97d., fuel being responsible for no less a sum than 1·06d. The fact is, says Mr. MURRAY, "the available water-power did not come anywhere near its calculated value, with the result that from the end of May until the end of November it was necessary to run a portion of the day on steam only. About midsummer there was so little water in the Teme that as much as 75 per cent. of a total week's running hours were done on steam power"; and as the engines are all of 286 I.H.P. a low engine load-factor was inevitable. Then Staffordshire coal was objected to by the surrounding inhabitants, and Welsh smokeless had to be partially substituted. So much for the outgoings. Excluding meter rents and such-like adventitious aids which bring the figure up to 3·16d. the average price realised at Worcester per unit sold was only 2·73d., an undesirable consummation which was mainly due to the contract to sell energy to the Water and Sewerage Committee at 1d. a unit; all for the sake of a day-load. As the Water and Sewerage Committee took no less than 42 per cent. of the entire output of the station, the average price of 3·99d. per unit which was realised for the balance of the output did not avail to prevent a nett deficit of some £1,400 on the year's operations.

OF course, Worcester will do better than this as time goes on. Moreover, there was undoubtedly a most unfortunate concatenation of unfavourable circumstances. Just when the water failed, costly Welsh coal had to be burnt, and so on. But the question remains, was it worth while to go so far to fare so ill? Was it business to contract to supply nearly one half of the entire output at a price which could not possibly pay unless water-power were available? And water-power in this country, where we have no series of inland seas to perform the useful function of a natural reservoir, is notoriously not to be relied upon.

PROF. SILVANUS P. THOMPSON advanced an ingenious hypothesis at the Physical Society last week in regard to the cause of the lag of apparent resistance and of current in an alternating arc behind the phase of impressed potential difference. The existence of this lag, he said, pointed to a phenomenon "in the nature of a back electromotive force;" and it will be remembered that some time ago Prof. AYRTON showed that this apparent back electromotive force resembled that of the self-induction of a coil when an alternating potential difference is impressed on its terminals. The cause of this much-debated

Digitized by Google

phenomenon Prof. THOMPSON now sought in a probable lag of temperature of the carbon behind the current. It does indeed seem reasonable that a "thermal flywheel" action of the carbon should throw the phase of temperature behind the phase of current. Nor is it altogether improbable that the element of non-ohmic or elastic resistance in the total apparent resistance is due to a directly thermo-electric phenomenon. It occurs to us, however, that there should be no lag between the phase of temperature and the phase of intrinsic brilliancy, and that Prof. THOMPSON's hypothesis might be put to an exact test by seeing whether a back electromotive force in step with the intrinsic brilliancy would be sufficient to account for the observed facts. On the other hand, it is just possible that something may happen in the alternating arc—where things occur which nowhere else occur—to throw the back electromotive force out of phase with the intrinsic brilliancy as photometered. It might, for example, be in phase with the intrinsic brilliancy of the 2nd, 3rd or *n*th stratum of carbon molecules beneath the surface of the crater—an awkward place to probe with a photometer.

ANOTHER matter relating to the alternate-current arc, and one possibly of more practical importance, was discussed at the same meeting. Conflicting statements have from time to time been put forward by various authorities, in regard to the relative efficiencies of alternating and continuous arcs. On the one side, Prof. THOMPSON has asserted that there is no inherent superiority in the continuous current over the alternate current, so far as light production is concerned. On the other side, Prof. FLEMING and Mr. PETAVEL have found that under what the former calls "semi-practical" conditions the continuous-current arc gave twice the light that was obtained with equal watts from an alternate arc. Arc lamp makers will be pleased to hear that there is now professional unanimity in respect of the uncertainty of these "semi-practical" conditions; and that at the Physical Society there was general agreement that it is impossible to settle *à priori* that there is any intrinsic difference between the two kinds of current, as regards their arc-light-generating capacity.

INDEED, attention seemed to be called away from the differences of currents and directed to the difference between makes of carbons. Both Prof. AYRTON and Prof. THOMPSON strongly insisted on the probability that the best quality of carbons for any given lamp will depend not only on the class of current used, but also upon the volts, watts, and even the frequency. The use merely of cored positives for continuous and solid positives for alternate arcs, or the use of carbons of different diameters in the one case, and of equal diameters in the other, does not constitute sufficient selection. Apparently we ought to adapt the quality and size of the carbons to each particular system of supply. Evidently, too, from Mrs. AYRTON's latest discovery, we must expect to find the quality of carbons changing with time; and the value of a make of of carbon, as of a vintage, may improve with age. These considerations, while they may serve to put arc lamp makers on the track of improved methods, will not bring unalloyed happiness. The necessity for so many different qualities of carbons, and the care needed in making a proper selection, will neither conduce to cheapness in arc lighting nor to simplification in the manufacture and supply of lamps. Probably, however, the makers will be content with only "semi-theoretical" conditions.

IT is not always easy to decide what quantities to keep constant, when working with several variables; and Prof. FLEMING's researches on alternate-current arcs are a case in point. But his comparison between a continuous and an alternating arc, in which the power supplied is kept constant and the other variables "are left to look after themselves," as Prof. FLEMING puts it, does not strike one as being strictly logical. In fact, we can find no better illustration of this comparison than the one suggested by Prof. AYRTON. Imagine a comparison between continuous and alternate currents for incandescent lighting, in which two sets of lamps were taken, quite irrespective of their voltages, and supplied with equal amounts of power at the same voltage. The continuous-current glow lamps might be made to appear any number of times better, or worse, than the alternate-current lamps, merely because essentially important variables were left to take care of themselves. Before we can compare the two kinds of arc, we must discover what are the best conditions for each. We are glad to learn that this is what Prof. FLEMING and Mr. PETAVEL intend to do.

THE patient efforts of Mr. D. MCFARLAN MOORE to obtain a useful degree of illumination by means of his so-called "etheric" light, are meeting with a gradually improving success. He has now been able to photograph himself by its rays with an exposure of only three minutes; and the reproduction from the untouched negative which the *Electrical Engineer* of New York publishes as a supplement is a very respectable picture. The photographs were taken in a room 10ft. by 11ft., with four vacuum tubes placed along the cornices, each tube being 9½ft. long and 1½in. in diameter. The glow in these tubes was produced by an interrupted current, the circuit being broken 100 times per second by one of Mr. MOORE's high-vacuum contact-breakers. The interruption occurring in a vacuum so high that glow discharge cannot take place in it gives rise to an enormous electromotive force of self-induction; and, at the same time, the removal of the atmosphere from around the contact-breaker increases the effectiveness and frequency of its movements. It is to be regretted, however, that our contemporary publishes no data which would enable an electrical engineer to form an idea of the power expended.

Cable Interruption:—

	Date of Interruption.
Puerto Plata—Martinique	December 19, 1895.

Electrical Communication with Lighthouses.—The Royal Commission will probably issue a fourth report in the course of the next few months. The final report will not be ready until the end of the year.

French Telegraphic Enterprise.—A project in connection with the establishment of submarine cable communication between France, North America, and the Antilles has been passed by the French Chamber.

The Islington Central Station.—The Lord Mayor and the Sheriffs of London drove in state to Islington on Wed-

Digitized by Google

nesday afternoon last, and formally inaugurated the electric lighting station which has been constructed by the Islington Vestry in Eden-grove, Holloway. There was a very large attendance.

Personal.—Mr. H. J. S. Heather, A.M.Inst.C.E., who was sent out by Messrs. Easton, Anderson and Goolden to erect the electric power transmission plant for Moodie's Gold Mining and Exploration Company, has now been appointed engineer to the latter company. Considerable extensions of the present plant, the capacity of which is 250 H.P., are in contemplation.

"Booster" Patent Litigation in America.—The Siemens and Halske Electric Company of America has just brought an action against the Toledo Traction Company for an infringement of the so-called booster patent, No. 417,668, issued December 17, 1889. This patent is looked upon by its owners as a fundamental one, and great interest in the litigation just begun is felt in America.

Expiring Patent.—On Tuesday next, the 10th inst., will expire patent No. 1,163, of 1882, granted to Edward Weston, of Newark, U.S.A., for "IMPROVEMENTS IN ELECTRIC LIGHTING APPARATUS." The invention relates to the Weston arc lamp, and the specification describes the mechanism of the lamp. There are claims for (1) the combination of magnets and clutch gear, (2) change-over mechanism, and (3) an arrangement of carbon carriers.

Sleet on the Chicago Elevated Railway.—Great annoyance was caused to passengers on the Metropolitan Elevated Railroad in Chicago on the night of January 22nd. The current is delivered to the cars through a third rail. A sleety rain caused a coating of wet ice to form and short-circuit the whole system until the ice could be cleared from the line, which took several hours. As drops of rain fell upon the ice, sparks were given out, and at times the whole line glowed as if it were ablaze.

The Hopkinson Three-Wire Patent.—On Saturday last, before the Judicial Committee of the Privy Council, motion was made by Mr. Graham for permission to admit the caveat of the Richmond Electric Lighting Company against the petition for the prolongation of this patent. Counsel admitted that the time for lodging caveats—the 24th ult.—had passed, but he hoped their Lordships would relax the rule in this case. The motion was, however, dismissed.

The British Association.—The presidents of the various sections of the British Association (Liverpool meeting) have now been chosen. The Presidents of the three sections which concern our readers are as follows:—Prof. J. J. Thomson (Section A), Dr. Ludwig Mond (Section B), and Sir Charles Douglas Fox (Section G). Prof. Flinders Petrie, and probably Sir Andrew Noble, will deliver the evening discourses, and Dr. J. A. Fleming will give the lecture to working men.

Post Office Telegraphs.—A Parliamentary return has been issued showing the gross amount received and the gross amount expended in respect of the telegraph service from the date of the transfer of the telegraphs to the State to March 31, 1895. The total receipts between 1870 and 1895 were £43,137,892 7s. 6d., and the total expenditure (including £2,636,982. 2s. 3½d., balance to meet interest on stock created on account of the telegraph service and the redemption of debt) was £43,967,675 15s. 8¾d., leaving the balance of receipts over expenditure at £829,783. 8s. 2¾d.

A Wire-Wound Flyweeel.—At the works of the Mannesmann Tube Company, in Germany, there has recently been erected a large wire-wound flywheel. The carcase of the wheel is of cast steel, with plate steel flanges forming a peripheral groove. Into this groove the toughened steel wire is wound, so as to form the body of the rim. Some 50 tons of No. 5 steel wire is used for this purpose. The wheel, which is 20 feet in diameter is driven at 240 revolutions per minute, thus the peripheral speed is normally about 260 feet per second. This wheel, therefore, has about three times the speed and more than nine times the regulating power of a cast-iron wheel of equal mass.

A Westinghouse-Baldwin Locomotive.—The first locomotive made by the Westinghouse-Baldwin combination has just been completed, and contains some departures from former practice. The locomotive is 38ft. long and 9ft. across, with an eight-wheel truck. There are four motors each of 200 H.P., one connected to each axle of the trucks. The motors are geared, it being believed that this will give a higher efficiency, while the cost of manufacture is less. The gear has been designed for a maximum speed of 75 miles an hour, although this could be pushed to 125 miles an hour if demanded. The weight of the locomotive completely equipped is 80 tons, and the cost is stated to be less than one-third the cost of the locomotive used in the Baltimore tunnel, which was $50,000.

An Imperial Elektrotechniker.—The German Emperor, of course, takes the liveliest interest in all technical matters, and to bring himself up to date in electrical subjects, he "commanded" a lecture by Prof. Slaby at the Technical High School at Charlottenburg on February 10th. In the course of two hours—such was the aptitude of the Imperial student—Prof. Slaby was able to run through several subjects, viz., electric transmission of power, the latest developments in electrochemistry, electrometallurgy, water-power plants, the different methods of electric lighting, and the electrical production of calcium carbide. After the lecture the Emperor held the usual *critique*, and ultimately granted Prof. Slaby the Order of the Crown "of the Second Class."

Research Fellowship.—The Executive Committee of the City and Guilds of London Institute have awarded the second Salters' Company's Research Fellowship for the encouragement of higher research in chemistry in its relation to manufactures to Sidney Williamson, Ph.D., F.I.C., F.C.S., who was for two years a student at the City and Guilds Technical College, Finsbury, and subsequently for three years at the City and Guilds Central Technical College. The Fellowship is tenable at the latter, and Dr. Williamson proposes to work on some questions bearing on food stuffs generally, more particularly the examination of some definite albumenoids, with the ultimate object of ascertaining the influence of various manures on the growth of crops in so far as *quality* of produce is concerned.

Telegraphic Communication with India.—In the House of Commons last week Sir J. Leng asked the Secretary to the Treasury, as representing the Postmaster-General, whether, in view of the restrictive effect of the present high tariff for telegraphic messages between the United Kingdom and India, he would favourably consider the proposal of the Bengal Chamber of Commerce that the charge should be reduced from 5f. to 3f. per word, and endeavour to give effect to the recommendation at the forthcoming International Telegraph Conference. Mr. Hanbury stated that the Postmaster-General could not find that such a proposal had reached him from the Bengal Chamber of Commerce, and he thought it was more likely to have been addressed to the Government of India, which was directly concerned in the matter. He had, however, received representations on behalf of the merchants and others in this country who used the telegraph to India, and he was in communication with the cable companies on the subject.

Electrolysis at St. Louis.—The annual report of Mr. A. J. O'Reilly, Superviser of City Lighting at St. Louis, tells, says the *Street Railway Review*, of the steps taken during 1894 and 1895 to learn the extent of, and to prevent electrolysis. In April, 1894, a circular letter was sent out to all persons engaged in placing pipes of any kind underground, requesting their co-operation by informing the Superviser of City Lighting as to any evidences of electrolysis discovered by them. Fourteen people responded to this request, and 20 cases of electrolysis were reported. These reports do not seem to indicate a very alarming condition of things. In addition to the reports, and in order to find out more accurately to what extent electrolysis was taking place, copper plates were put in the ground at the bottom of stop-valve boxes and ground fire plugs. At each place there were two plates 1½in. by 6in. and weighing 15 grammes. One of these was connected with the water pipe and the other was not. They were carefully cleaned and weighed before putting in the ground. After being buried for 100 to 150 days they were taken out, cleaned and weighed again.

Digitized by Google

The difference in weights gave the effect of electrolysis. The report states that in some cases the tramway rails were examined and found to be reduced fully one-third around the base. It is recommended that promiscuous connecting of rails and water pipes be not allowed, but that if this is done it be only in a systematic manner.

The New Heilmann Electric Locomotives.—At a recent meeting of the Société des Ingénieurs Civils de France, M. H. de Grièges gave some further particulars with regard to the new Heilmann locomotives which may interest our readers. The engines adopted to drive the generators will be six-crank engines designed by M. Mazen, track inspector of the Compagnie des Chemins de Fer de L'Ouest. These engines will run at 400 revolutions, and will only weigh eight tons. They will have a piston stroke of 15·6in. The first Heilmann locomotive, "The Rocket," could only develop 600 H.P., whilst the two new "locos" on order will develop 1,400. This increase is arrived at by increasing the grate area from 26 sq. ft. to 36 sq. ft. The resistance to rolling of the new Heilmann locomotive is expected to only be about 13lb. per ton, as against 20 to 24 in the case of the compound steam engines now used for the same sort of traffic. The railway company, not wishing to bind itself to any particular system, is about to instal an overhead trolley line between Saint-German-Ouest and Saint-German-Grande-Ceinture. It is hoped, therefore, that this summer two system of electric traction will be tried on this section, viz., the two new Heilmann locomotives and trains run on the overhead trolley system.

The Relationship of Mathematics to Mechanics.—The following comments are made by *Engineering* on the coalescence of mathematics and mechanics in a professorial chair at South Kensington. Mechanics in such circumstances, we may add, are usually only *mixed* mathematics :—

"We regret to note that the Science and Art Department are calling for candidates for the chair of Mathematics and Mechanics at the Royal School of Mines, South Kensington. We believe we are right in stating that no one person is competent to teach both these subjects efficiently. The successful candidate is likely to be either a mathematician with little or no knowledge of engineering, or an engineer with a knowledge of mathematics limited solely to the practical applications of the science. Of the two, the former is probably the more pernicious, and unfortunately it is almost certain that one of this class will be appointed. If this should be the case, it is to be hoped that, at any rate, the gentleman in question will not be responsible for the papers set in Steam and Applied Mechanics in the May examinations of the Department. The least the authorities can do, since they are determined to maintain the objectionable connection between the two subjects, is, at any rate, to confine the mischief done to the college itself, and not let the unfortunate students at our evening classes suffer. These latter, as matters stand, exercise no little self-denial in endeavouring to extend their theoretical knowledge by working in the evenings, after a hard day in the workshops, and it is not too much to ask that the time thus gained from their scanty leisure should not be wasted by the misdirection of their studies. Unfortunately there is in some quarters a disposition to look on such classes less with a regard to the benefit of the students, than with a view to increasing the emoluments of teachers and examiners. This state of mind is by no means confined to Government officials, for our universities have done much bad work in the same direction by appointing as extension lecturers young men often ignorant of their subjects, simply because they have taken a good degree, and there did not happen at the moment to be a fellowship open at their college."

The Action of High-Frequency Currents on Bacterial Toxines.—At a recent meeting of the Académie des Sciences MM. d'Arsonval and Charrin read an interesting Paper on this subject. The authors state that, having investigated the effects of the various forms of electrical energy on the bacteria themselves, they thought it would be interesting to ascertain the effects upon bacterial secretions. They allude to the experiments of Smirnoff and Kruger with continuous currents, and state that, owing to the difficulty of differentiating the electrochemical from the purely electrical phenomena, experiments carried out by means of the electrolysis of solutions containing bacterial toxines do not yield reliable results. To eliminate electrolytic effects, and because they found from preliminary trials that 7 coulombs of induced uni-directional electricity had more effect than 78 coulombs due to an ordinary continuous current, MM. d'Arsonval and Charrin employed currents of extremely high frequency (225,000 oscillations per second, according to Thomson's formula) derived from condenser discharges. The average strength of the initial discharge current was 50 amperes; the mean value of the current traversing the toxine solution was 0·75 ampere, and the mean current density was 0·250 ampere per square centimetre. The experiments made show conclusively not only that the toxines are greatly weakened by exposure to the action of high-frequency currents, but that the toxines so weakened may be used to render persons immune. Diphtheritic and pyocyanic toxines were investigated. A quarter of an hour exposure to electrical influence sufficed to diminish the strength of the toxines by about 50 per cent.

The Frédureau Diffusing Globe.—The following is an abstract of a report on the diffusing globes of M. Frédureau and their application to electric illumination, prepared by Prof. Silvanus Thompson. The globes are of transparent glass, so shaped as to properly distribute and diffuse. Assuming the globe to present, at its interior surface, a smooth figure of revolution, spherical, spheroidal or cylindro-spherical, the light which passes through the transparent envelope in nearly radial directions may be directed downwards by shaping the outer surface in prismoidal zones, each of which has its lower surface horizontal and its upper surface a portion of a paraboloid of revolution confocal with the luminous centre. A second solution consists also in shaping the outer surface with prismoidal zones to reflect the light; but these, instead of being bounded by portions of confocal parabolas above, and horizontal surfaces below, are calculated according to a different plan. The lower faces of the annuli are all made to be portions of cones described around the vertical axis, and radiating from the common centre; whilst the upper faces, the breadth of which is determined by the limiting angle of total reflection, are also conical instead of parabolic. Both constructions concentrate the beam downward generally, but also disperse it around the lamp in all directions; and both soften the light for the observer's eye. Both constructions also produce another effect on the light, namely, they slightly change the tone of the light by modifying the proportion of rays of higher refrangibility, which ordinarily give the arc light its bluish hue. The globes tested are manufactured of glass or crystal, moulded with a sharpness of surface which leaves nothing to be desired, and which are quite inexpensive when their cost is compared with the cost of producing similar globes by cutting. This result is due to the care at first bestowed on the production of the moulds that are to be used. By photometric measurements the globes have in every case been found to be effective in concentrating the light in the desired direction. With a 16 c.p. (nominal) incandescent lamp and a diffusing globe provided with an upper hemispherical reflector, Prof. Thompson made a series of measurements to test the actual increase in the light in the downward direction, with the results given below. The direction downward was taken as zero :—

Angle at which light was measured.	Amount of light with naked lamp.	Amount of light with reflector only.	Amount of light with reflector and diffusing globe.
0°	8	17·5	34
10°	8·5	17·5	24
20°	9·25	18·75	22
25°	10·25	15·2	16·25
30°	11·5	15	12

From this it will be seen that the lamp was giving only eight candles in the downward direction until provided with the diffusing globe and reflector, but when so provided it gave a light downwards of 34 candles. This increase was, of course, obtained by utilising rays that would otherwise have been wasted by being emitted upwards, or in directions where they would produce little result. A prolonged and careful examination of the effects obtained in interior illumination by the aid of the diffusing globes convinces Prof. Thompson that the redistribution of light effected by these globes is of very real advantage. For all effective purposes a 16 c.p. lamp, provided with a diffusing globe, illuminates an apartment better than a 32 c.p. lamp not so provided, thereby effecting a distinct economy. For, if we assume the 16 c.p. lamp to take 60 watts at 6d. per unit, the 16 c.p. lamp would cost under 0·36d. per hour (or about ⅓d.), and the 32 c.p. lamp would cost 0·72d. per hour (or over ⅔d.). The saving in cost of light at the end of a 1,000 hours of lighting would therefore be nearly 30s., besides providing a light more agreeable to the eyesight. Messrs. A. and E. Cohen, of 2, Bury-street, St. Mary Axe, are the sole agents for Great Britain and the Colonies.

BRISTOL MUNICIPAL ELECTRIC SUPPLY STATION.

Early Developments.

The instructiveness of an electric supply undertaking, as, indeed, of all commercial ventures, increases according to the length of time during which experience has been gained by means of it. When a new station is opened, more or less with a flourish of trumpets, the associations of the event savour more of excitement and sentiment than of real instruction. But when any concern has been running for some time, we can note not only of what particular plant it is composed, but also the degree of suitability and success in its selection. Accordingly, we turn to the Bristol municipal electric supply station, which has been running since the autumn of 1893, expecting to learn more from it than we should were it only just now commencing its career of full-fledged existence.

Before, however, describing either the details of the station and its outlying network of mains and sub-stations, or the history of the concern since the day of commencing work, we will briefly notice the earlier stages of development which preceded the inauguration. Bristol was one of the earliest of British towns to have the matter of its electric supply undertaken by the municipal authorities. For, in 1883, the Bristol Sanitary Authority acquired a Provisional Order giving them the necessary powers. During many years, however, this Order lay dormant, the authorities having been advised by their consulting electrical engineer, Mr. W. H. Preece, that electrical matters were not ripe enough to justify active steps. Thus passed the time until May, 1889, when Mr. Preece advised his clients that the time for action had arrived; and in the following June the consulting engineer presented a report recommending that the authorities should on their own account erect and run a supply concern. This they decided to do, and in December, 1890, Mr. Preece was instructed to prepare a report for a station to run 10,000 glow lamps and 60 arc lamps. A site for the station was selected adjoining the Floating Harbour, and most conveniently situated for obtaining water and coal. Mr. Preece's actual report, which was presented in March, 1891, contemplated the following items:—

Number of glow lamps	10,000
Number of street arc lamps	100
Total outlay on concern	£66,000

Subdivision of estimate:—

Buildings	£5,000
Plant	24,000
Mains	20,000
Distribution	6,000
Working capital	5,000
10 per cent. for contingencies	6,000
	£66,000

Estimated working expenses:—

Arc lamps	£2,520	per annum
Glow lamps	7,100	„
	£9,600	„

Estimated revenue:—

Arc lamps	£2,500	per annum
Glow lamps	10,500	„
	£13,000	„

The system recommended in this report was the high-pressure alternate-current system, with transformers in sub-stations, and 500-watt arc lamps, in a number of series circuits supplied with continuous current. Six sub-stations were contemplated at the start.

In April of 1891 Mr. Preece was joined by Mr. Gisbert Kapp in the capacity of consulting engineers to the authorities. The following July witnessed the first of a series of untoward events, which tended to delay the progress of the scheme. The authorities issued specifications for building contracts, but these were boycotted by the entire building trade. The reason seems to have been that these specifications were not drawn up according to the orthodox and eternal traditions of the building trade. The hitch, however, was overcome after a time, and the building trade tendered to plans prepared by Mr. H. Williams, architect to the electrical committee. It was found, at about this time, that the nature of the ground at the site would render it necessary to erect a strong river wall or buttress, and to pile drive the entire site. These things were decided upon in December, 1891, and were carried out at a cost of about £12,000, the pile driving alone costing £9,659. About this time it was decided that, owing to the large percentage of corrosive and other chemical matter in the harbour water, and the amount of mineral matter held in suspension, Lancashire boilers should be used. The same considerations rendered it necessary to decide upon surface condensers, in order that very little feed-make-up might be required (*see* section on Machinery Room Equipment). During 1892 the following tenders were accepted:—

1892.	Plant.	Firm.	Sum.
May	Boilers.	Messrs. Tinkers.	£7,400
May	Dynamos.	Messrs. Siemens.	14,011
October	Buildings.	Mr. C. A. Hayes.	13,346
December	Condensers, pumps, steam pipes, &c.*	Messrs. W. H. Allen and Co.	...

During the following year, 1893, the subjoined further tenders were accepted:—

1893.	Plant.	Firm.	Sum.
February	Distributing cables.	Messrs. Siemens Bros.	£16,580
May	Sub-station transformers.	Brush Electrical Engineering Co.	1,752
May	Switchboard, battery, &c.	Mr. F. M. Newton.	1,553 10s.

It is interesting to mention that in October, 1892, Mr. H. Faraday Proctor was appointed electrical engineer to the Bristol Sanitary Authority, and took charge on the spot of the various operations of the contractors. Mention might also be of interest of the building strike which, in August, hindered operations at the river wall. The original scheme of 1883 had contemplated supply to only a portion of the city; but in November, 1892, an extension of the scheme took place, involving supply to the entire city. In June of the following year, 1893, the building contractor asked for additional payment, owing to the unforseen costliness of the building operations, but this request the authorities refused. In the following August the electrical authorities came into collision with the Poor-Law Guardians in regard to the assessment of the buildings and plant. It seems that a gross assessment of £3,000, or a net assessment of £2,000, was made by the latter body. It may here be mentioned that the Bristol electric lighting concern, from the outset until the present time, has been saddled with heavy charges on this head; and in 1894 the assessment was at the rate of 1·18d. per unit. (*See* section on Progress since Starting.)

Supply to the consumers was commenced at the end of August, 1893, and to the street arc lamps in November of the same year. By the middle of December all the streets in the area agreed upon were being supplied with current, the station was working with 90 per cent. of its power utilised, and there were 14,000 lamps—4,000 lamps above the estimate—already connected to the mains. Up to this date a sum of £80,000 had been expended upon the concern.

The Station and Out-Works.

Locality of Station.—The accompanying map (Fig. 1) shows that the supply station is situated within the area of supply, and somewhat near its present boundary. All around the station, but more especially to the north-westward, are districts likely to take up the electric light as fast as cables are laid down. In the immediate neighbourhood are business premises and factories; but further to the westward and northward are well-to-do residential suburbs, through some of which cables have already been laid. The advantages of the site in respect of water and coal supply—owing to the adjoining Floating Harbour—have been mentioned; and the only drawbacks which the site has had have been due to the rotten-

* The tender of Messrs. Woodhouse and Rawson for this plant had originally been accepted, and was, in December, 1892, transferred to Messrs. W. H. Allen and Co

Digitized by Google

ness of the ground and the highly corrosive nature of the harbour water, this last being due to the chemical works further up the harbour.

Present Equipment of Station.—At the present time the plant actually installed or on order, for the arc lighting and general supply, comprises the items set forth in Table I. Of this plant, one 210-kilowatt alternator set has been erected since the starting, and one of equal size is now about to be erected. An extension of the feeder switchboard has also taken place, owing to the addition of several new feeders.

Table I.—*Present Equipment of Station.*

Plant.	No.	Remarks.
Boilers	4	Lancashire, 28ft. by 8ft.
Boilers	3	Lancashire, 24ft. by 8ft.
Stoker engines	2	Vertical engines driving coal conveyers and stokers.
Feed pumps	2	Kirkaldy type, built by Owen, each 4,000 gallons per hour max. Duplex direct-thrust type.
Donkey pump	1	2,500 gallons per hour.
Feed heaters	2	Feed heated by live steam on occasion.
Water softener	1	Howatson's.
Tank	1	For softened water. Capacity 3,760 gallons.
Tanks	2	For cold water, on roof. Each 14ft. by 14ft. by 6ft. 6in.
Tank	1	For air pump discharge. Capacity 790 gallons.
Hot tank	1	For feed pump suction. Capacity, 1,200 gallons.
Reservoir	1	Excavated beneath boiler house, to serve as a cold well for the circulating pumps &c. Supplied with harbour water through a culvert and sluice valve.
Engines	4	Willans (IIIS. type), compound, three-crank, each of 360 I.H.P. Coupled direct to alternators.
Engines	2	Willans (GGGS type), compound, three-crank, each of 150 I.H.P. Coupled direct to alternators.
Engines	4	Willans (GGS type), compound, two-crank, each of 100 I.H.P. Two coupled direct to exciters, two coupled direct to arc light machines.
Gas engine	1	38 H.P. "Stockport" gas engine and small alternator. Formerly used for the day-load, but now in disuse owing to not being large enough to take day-load.
Condenser	1	W. H. Allen's surface condenser, surmounted by feed-make-up evaporator. Capacity of condenser, 30,000lb. exhaust steam per hour.
Air pumps	2	W. H. Allen's vertical direct-coupled type. Capacity of each pump 250 c.ft. per minute. Pumping engines are compound, with cylinders 10in. and 16in. diameter. Pump barrel, 16in. diameter; stroke, 10in.
Circulating pumps.	2	W. H Allen's "Conqueror" centrifugal type, direct-coupled to vertical compound engines. Capacity of pump, 2,800 gallons per minute, raised from 15ft. fall. Engine cylinders, 6in. and 12in. diameter; stroke, 12in.
Oil filter	1	Filter of coke and shavings in tank between air-pump discharge tank and hot tank, with by-pass.
Alternators	4	Siemens. Each of 210 kilowatts, driven direct by IIIS engine.
Alternators	2	Siemens. Each of 88 kilowatts, driven direct by GGGS engine.
Exciters	2	Siemens. Each of 50 kilowatts, driven direct by GGS engine.
Arc light dynamos	2	Siemens. Each for 80 amperes, at 600 volts. Driven direct by GGS engine.
Battery	1	A small storage battery of 54 cells in a room on the station, is used for exciting the alternators, on occasion, and for some of the station lights.
Switchboards	2	One panel switchboard for five alternators and 17 feeders, and one arc and exciter switchboard.

Boiler House Equipment.—All seven of the boilers are of the Lancashire type, with Galloway tubes in the flues, and are stoked mechanically by means of Vicars' automatic coking stokers. They were made and set by Messrs. Tinkers, Limited. Small Welsh coal, at about 7s. 6d. per ton, is used. The coal is brought alongside the station grounds in barges, from which it is hoisted on to the roof of the boiler house, where it is weighed and then shot into a coal pocket. Through a trap door in the bottom of the pocket the coal descends to the chain-and-bucket conveyor, whence it passes to the channels along which it is distributed to the several boiler hoppers. The conveyor gear, together with the range of four larger boilers, and the arrangement of the pipes, &c., in the boiler house, are well shown in the illustration in the SUPPLEMENT. A set of scale drawings of the boiler house is given in Fig. 2. It may here be mentioned that the performance of the boilers is a very satisfactory one; for example, when burning Welsh small peanuts, one of the 28ft. boilers evaporated 6,200lb. of actual feed-water per hour, and one of the 24ft. boilers evaporated 4,530lb. per hour, both working at 125lb. per square inch—the usual working pressure.

Between the range of four large boilers and the range of three smaller ones there is a glazed house or closed-in shed serving as a pump room. Within this room are the duplex pumps and the donkey pump. Immediately behind this pump room is a large tank, which serves as a hot well for holding the condensed steam from the surface condenser. This tank is situated close to the chimney, which is of brickwork 110ft. high and 17ft. exterior diameter at the base. As shown in Fig. 2, the chimney is of circular section, and is provided with separate inlets for the two batteries of boilers. There is a ventilated air space between the courses of the main chimney and the inner hot shaft at the bottom. An independent duplicate system of feed pipes supplies all the boilers, both sets of pipes being easily controlled by hand gear from the gangway along the boiler fronts. There is, however, but one feed inlet to each boiler, this being protected by a

Distributing Mains and Arc Mains in original contract.

Distributing Mains since added.

Extensions of Feeders where there are no Distributing Mains.

* Electric Tramway Terminus in Old Market Street.

double check valve. Feed water is usually taken from the hot well, the deficit of supply being made up by an evaporator attached to the condenser; but when requiring to fill up a boiler, after emptying, cold water is passed through two live steam heaters. The condensed steam from the surface condenser is cleaned of oil by being passed through a coke and shaving filter, as well as by the use of compounds which saponify the oil in the boiler. Each boiler is provided with only one steam standpipe, which supplies steam through a single 5in. branch pipe to the ring main in the engine-room. The arrangement of these branch steam pipes is shown in Fig. 2. A subsidiary 2½in. steam ring supplies the pump-room and feed heaters. The main steam ring is of 7in. and 6in. pipes. All the flanges and T-pieces of the steam pipes were electrically welded by the Bernardos process, and have been tested to 1,500lb. pressure. We may add that the boilers and steam pipes are fitted throughout with "Hopkinson" valves, made by J. Hopkinson and Co.

The following additional data in regard to the piping, &c., may be of use and interest :—

Table II.—*Feed and Steam Pipes.*

Main feed pipes	3in. diameter
Branch feed to boilers	2in. diameter
Feed delivery to heaters	3½in. diameter
Air pump discharge tank pipe to oil filter and hot tank	3½in. diameter
Suction from soft-water tank	4½in. diameter (C.I.)
Suction from cold well	3in. diameter
Discharge from tanks to water softener	3in. diameter
Steam branch pipes	5in. diameter
Safety-valve escape pipes	6in. and 8in. diameter (C.I.)
Feed pump steam ring	2½in. diameter
Blow-off pipes	3in. diameter
Main steam ring (in machinery room)	6in. and 7in. diameter

Machinery Room Equipment.—The general arrangement of the plant in the machinery room is shown in plan in Fig. 3, and a view of the room is also given in the SUPPLEMENT. The steam ring, which is not shown in Fig. 3, is rectangular in shape and embraces the entire area of the main machinery floor. It is suspended at a height of 10ft. 6in. from the floor, and is supported by brackets which are secured to the walls to a gallery running entirely round the room. The width of this gallery is principally about 3ft., but in one place it is widened out to an extreme width of 12ft. 6in., where it forms the switchboard platform. As already stated, the steam range is immediately below this gallery, an arrangement which conveniently allows of all the steam stop valves, whether on the ring or one of its branches, being worked from the gallery. At one extreme end of the machinery room, and at a lower floor level, the condensing plant is situated. At the other extreme end are the two 88 kilowatt alternator sets, direct coupled to 100 I.H.P. Willans compound two-crank condensing engines, controlled by variable expansion gear. These machines develop power at 2,100 volts, at a frequency of 93 cycles per second. Next to these, in line down the room, are the four larger alternator sets, one of which is not yet quite erected. Each of these sets will develop 210 kilowatts at 2,100 volts, at the same frequency. Arranged parallel with this line of alternators are four direct-coupled continuous-current generator sets. The two end machines

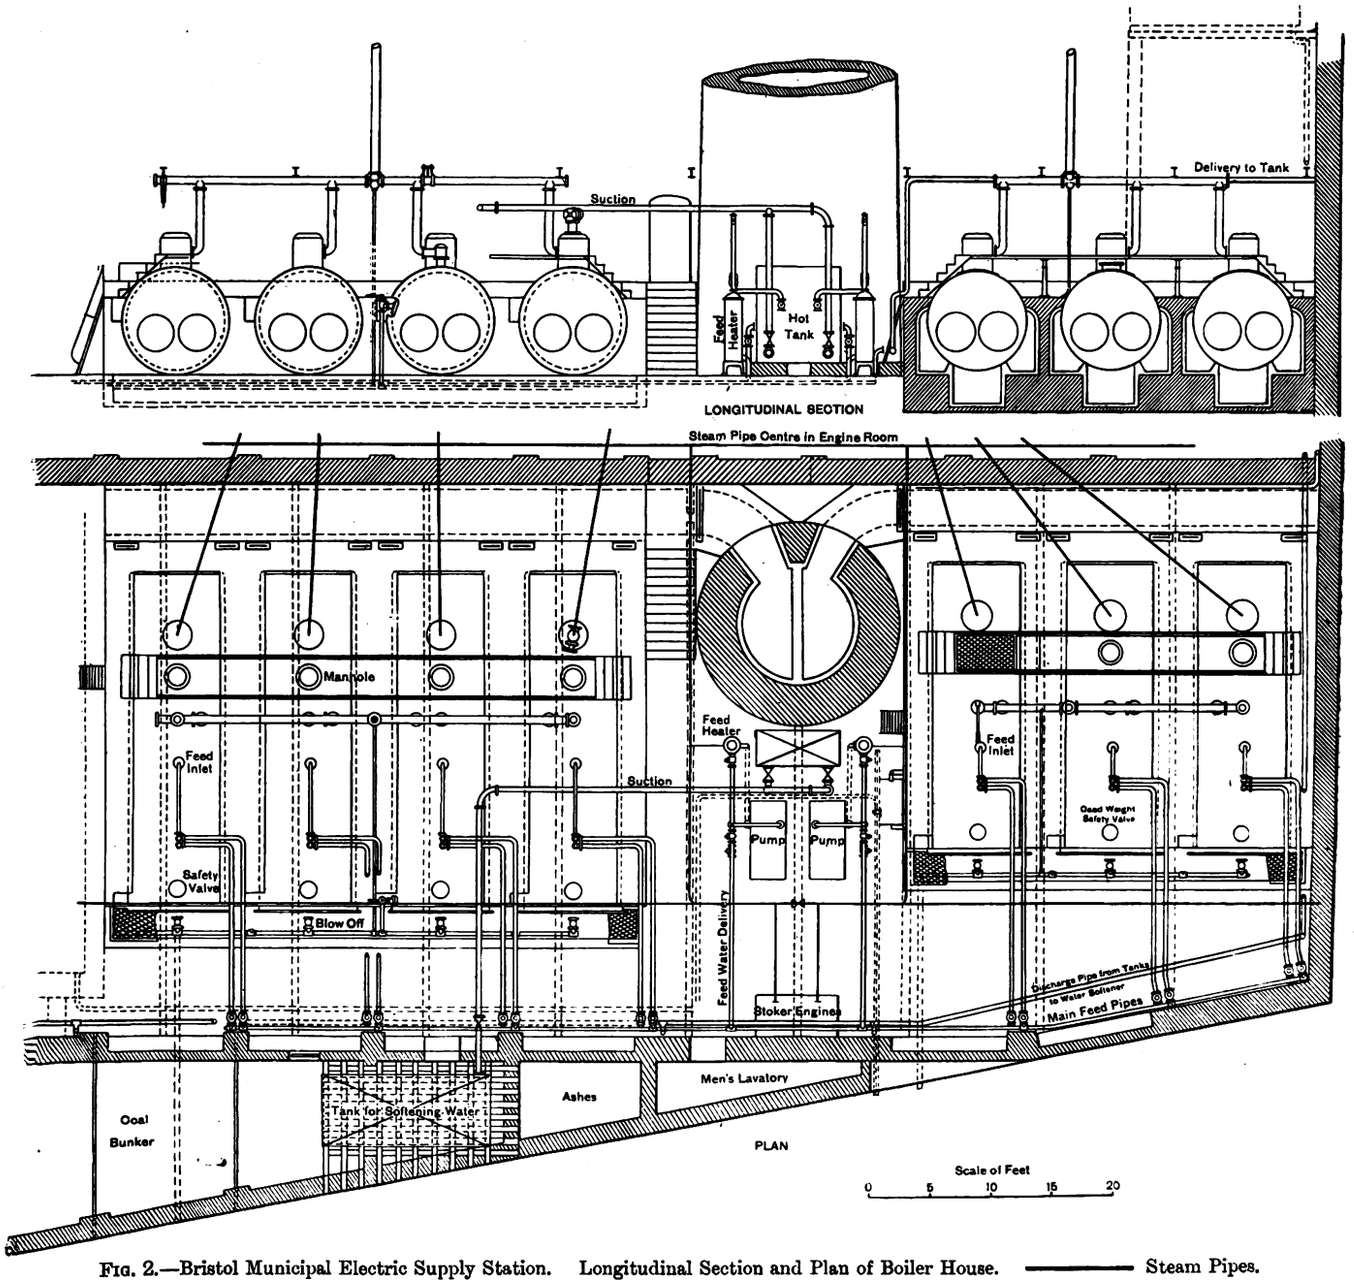

FIG. 2.—Bristol Municipal Electric Supply Station. Longitudinal Section and Plan of Boiler House. ——— Steam Pipes.

are used as exciters, and each will develop 50 kilowatts, either at 100 volts for exciting or at 130 volts for charging the small battery of storage cells. The other two of these are used for running the arc lamp circuits, and each set will develop 80 amperes at 650 volts. These four sets are each driven by a Willans compound two-crank 100 H.P. engine, with throttle gear. Space exists within the present steam

Digitized by Google

ring for two more of these continuous-current sets. There is a steam separator on each of the nine engines, but none at the boiler end of the steam ranges.

Exhaust Ring.—The exhaust main forms a ring parallel with the steam ring, but lying beneath the floor-plates. It is of 15in. internal diameter, with copper expansion joints. The pipes are anchored at the four corners of the ring, and are free to expand. The branch exhaust pipes from the engines are of 7in. W.I. pipe, with copper bends, for the 360 H.P. engines, and of 4in. W.I. pipe, with copper bends, for all the other engines. The main exhaust pipe to the condenser is 18in. diameter. There are three ways of dealing with the exhaust steam, and accordingly the ring is provided with

exists for two more condensers and the necessary extra pumps. A separate plan of the condensing plant, but, however, showing *two* condensers, arranged as at Bristol, is shown in Fig. 4. The condenser is of the surface type, and consists of an outer horizontal cylindrical shell, 4ft. 1in. diameter and 8ft. 6in. long between tube-plates, with a large number of longitudinal ⅝in. gun-metal tubes secured between these plates. A diaphragm at the front end of the shell divides the tubes into two sets, and provides that the cold water shall be carried twice along the length of the condenser. The total condensing surface is 2,422 sq. ft. Circulation is produced by two "Conqueror" centrifugal pumps, direct coupled to Messrs. Allen and Co.'s vertical compound

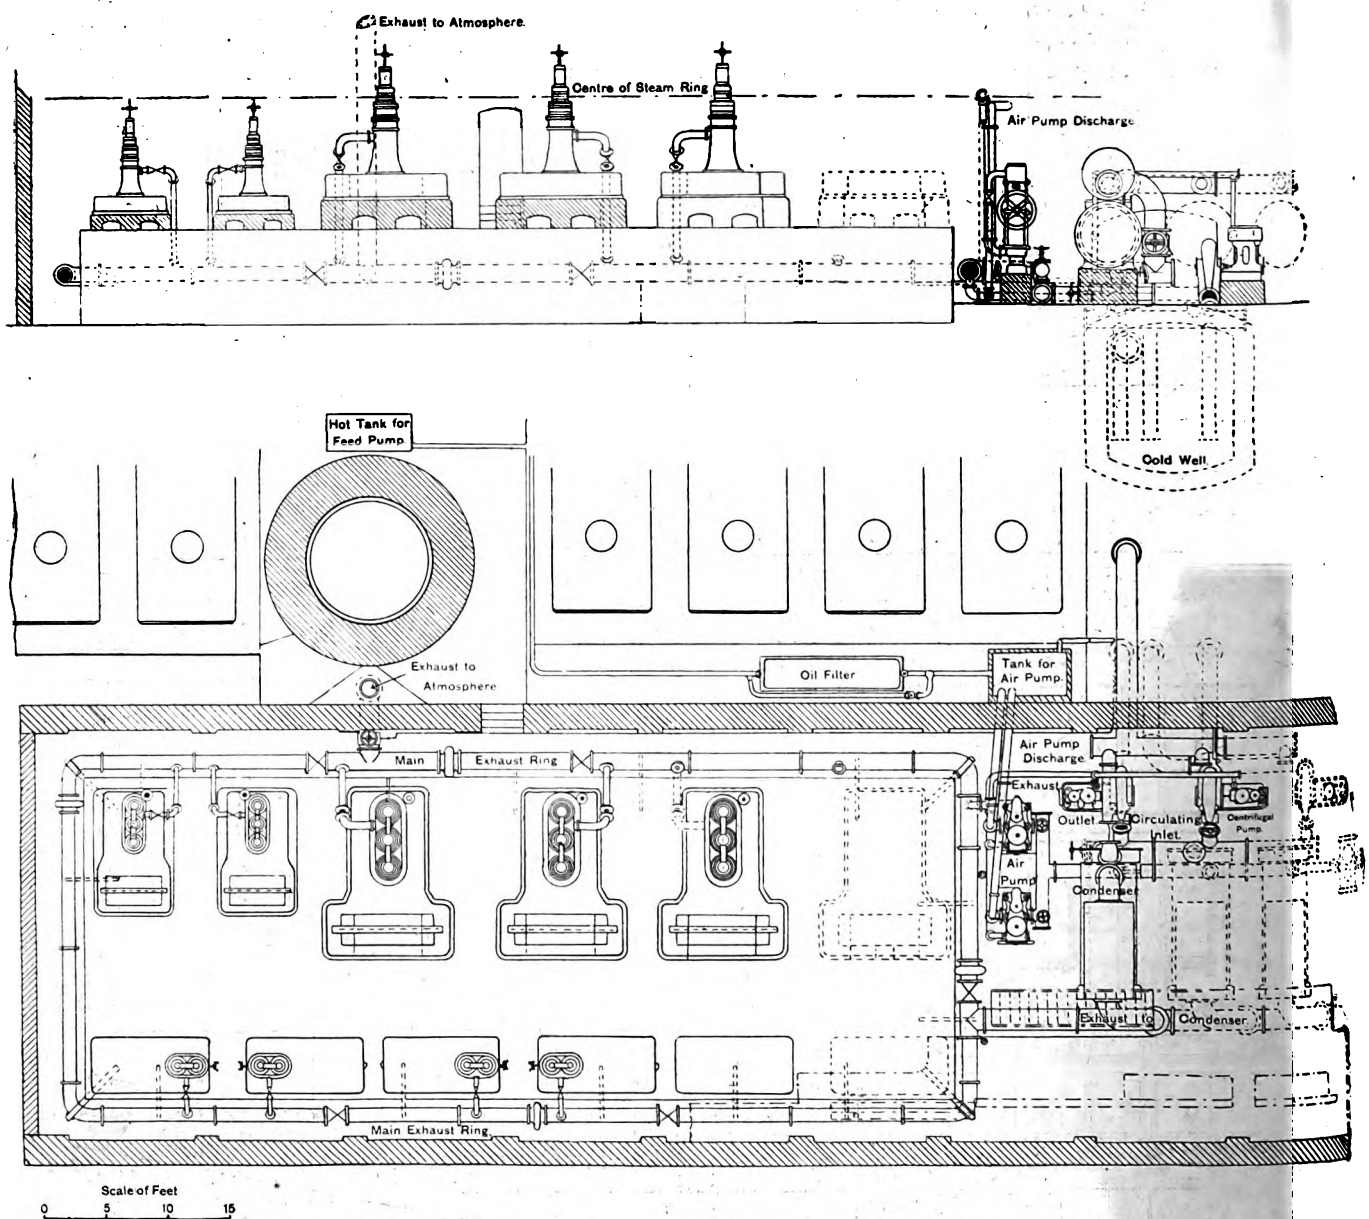

FIG. 3.—Bristol Municipal Electric Supply Station. Longitudinal Section and Plan of Machinery Room and Condenser Annexe.

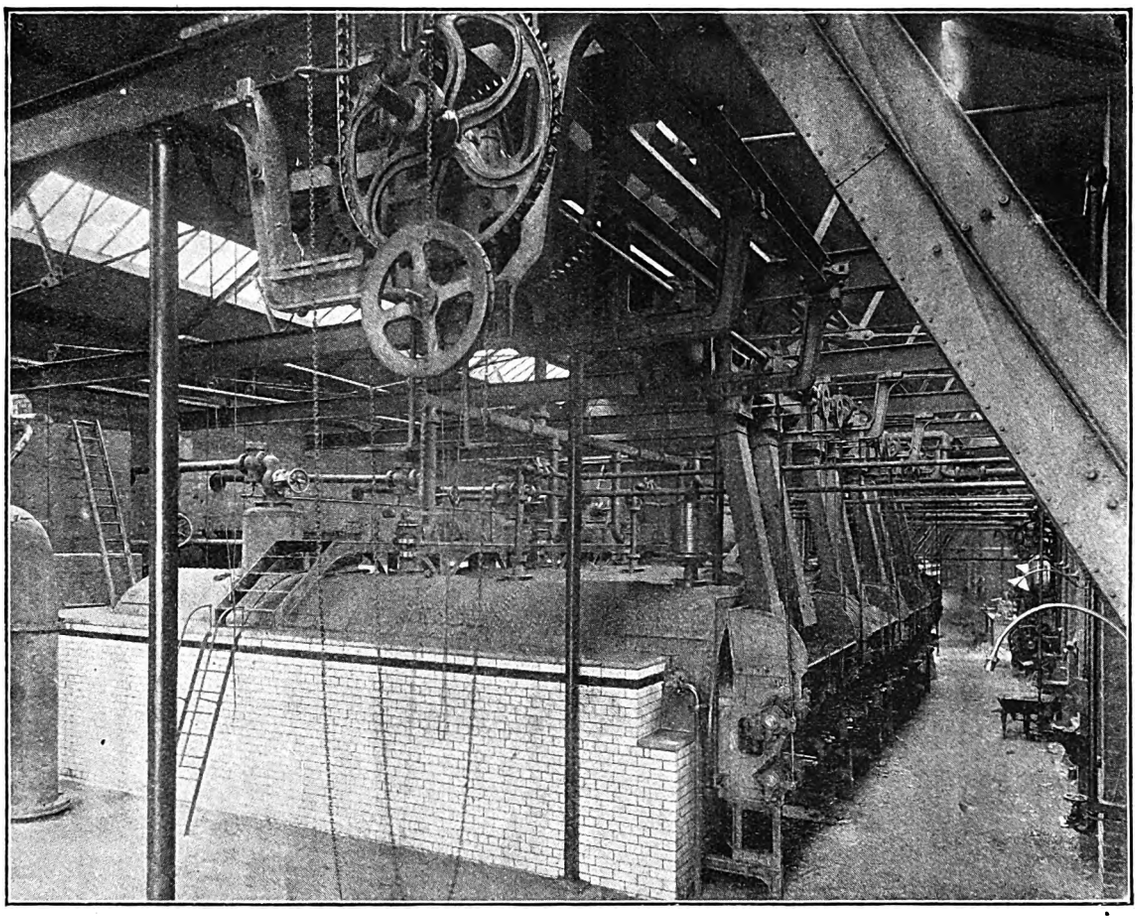
three discharge branches. One of these leads direct to the condenser, another to an air outlet which is erected beside the chimney, and the third to a water-sealed auxiliary trap, which is of use in changing over from non-condensing to condensing, or in the event of the air pumps failing. The air outlet consists of several 9ft. lengths of 16in. C.I. pipe, carried up the outside of the chimney and stayed at 9ft. intervals; the pipe terminating in a double-funnel cap, from which the exhaust is discharged into the atmosphere.

Condensing Plant.—The floor of the condensing annexe is 6ft. lower than that of the main machinery room, and is eached by a stairway from the latter. There is, at present, t one surface condenser with duplicate pumps; but space

steam engines. The engine cylinders are 6in. and 12in. diameter, and 12in. stroke, and the pumps are capable of raising 2,800 gallons of river water per minute from a depth of 15ft. A safety governor is fitted to each engine, which would come into action in the event of the pump losing water, and each pump is provided with a charging apparatus, by which it may be quickly charged before starting. The air pumps are two in number, and are direct-coupled to two vertical compound engines. Each pump has a capacity of 250 cubic ft. per minute. The engine cylinders are of 10in. and 16in. diameter, and the stroke is 10in. The diameter of each pump barrel is 16in. The piston rods of the engines are direct coupled at the cross-heads to the pump rods by means

Digitized by Google

BRISTOL MUNICIPAL ELECTRIC SUPPLY STATION.



VIEW OF BOILER HOUSE.

VIEW OF MACHINERY ROOM.

Digitized by Google

of two stiff rods working in guides. The cross-head also drives a crank shaft by means of a connecting rod, and thus turns a couple of small flywheels, which are keyed to the shaft. The flywheels are designed to give steady rotation at low speeds. A crank shaft governor controls the engine when the pump fails to lift water. These engines are well lubricated from an oil reservoir, the oil being distributed to each part through a separate pipe with a sight-feed regulator. Surmounting the condenser shell is the feed-make-up evaporator, which it will be convenient to describe at this point. This evaporator consists of an external horizontal cylindrical shell, within which is a smaller cylinder arranged like the flue of a Cornish boiler. The inner cylinder is transversely crossed by 26 diagonal circulating tubes of 2in. diameter, which communicate with the space between the two cylinders. This space is partially filled with harbour water from the cold well or reservoir beneath the boiler house; and a 3in. pipe forms a communication between the empty space in the upper part of the evaporator and the vacuum of the condenser, so that the pressure over the dirty water is very low. Through the internal cylinder of the evaporator the exhaust steam passes on its way to the condenser; and it is found that the temperature of this steam is sufficient to evaporate the dirty water at the low pressure of the vacuum. Thus the water is distilled over into the condenser and passes on to the hot tank along with the condensed steam. In the event of an extra large quantity of feed-make-up being required, live steam can be turned into the evaporator in place of the exhaust steam. It should be stated that the circulating water is discharged direct into the harbour and not into the cold well. The existing condensing plant is capable of dealing with 30,000lb. of exhaust steam per hour.

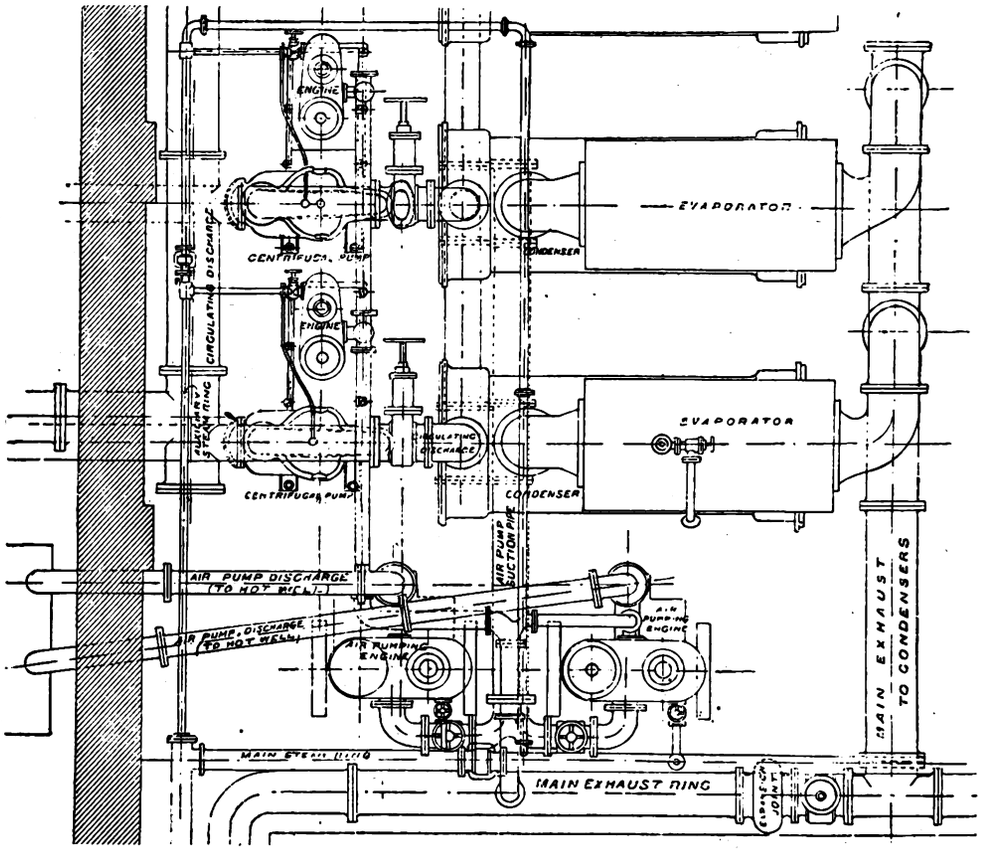

FIG. 4.—Plan of Condensing Plant at the Bristol Electric Supply Station.

Alternators.—All of the alternators are of substantially the same design, and were built by Messrs. Siemens Bros. and Co. The smaller machines are miniatures of the larger. The 210-kilowatt machines are of the $\left(\frac{W\,32}{4}\right)$ type, *i.e.*, each machine has 32 complete fields, with the poles set at 4in. pitch. The output is 100 amperes at 2,100 volts, at a frequency of 98 cycles, when running at 350 revolutions per minute. These machines are each coupled to a Willans III S engine, *i.e.*, three "I" engines side-by-side, and strengthened for extra heavy loads. The smaller alternators are of the $\left(\frac{W\,24}{3\frac{1}{2}}\right)$ type, with 24 magnet fields at $3\frac{1}{2}$in. pitch. Each develops 88 kilowatts, viz., 42 amperes at 2,100 volts, running at 465 revolutions per minute. In all the machines the armatures consist of flat coils, which, in each machine, are secured to a steel disc keyed to the shaft. The magnets are mounted on circular cast-iron frames on either side of the armature. The field-magnet cores are of wrought iron of high permeability, with wrought-iron pole-pieces rivetted on. Over the pole face a layer of ebonite is moulded and afterwards vulcanised *in situ*. The field-magnet coils are of copper wire; the armature coils, which are of sector shape and are secured to stout metal side plates, are wound with a strand of fine copper wires pressed into a flat strip and insulated with specially prepared tape. The insulation of these coils, including that between the coils and the brass cheeks or side plates, is prepared so as to enable the machine to withstand a high temperature for long runs.

Continuous-Current Machines.—The exciters are of the $\left(\frac{H\,B\,18}{20}\right)$ type—*i.e.*, the field-magnets are single circuit, or half the old type of D machine—and the drum armatures are bar wound; the armature is 18in. diameter, and the pole face is 20in. Each of these machines, coupled to a GGS Willans engine (*i.e.*, a strengthed doubled G type), develops 400 amperes at 130 or 100 volts, when running at 465 revolutions per minute. Both the arc light machines are built on lines similar to the exciters. They are single-magnet, drum-wound, bar armature machines of the $\left(\frac{H\,B\,18}{24}\right)$ type. Each machine is direct-coupled to a GGS Willans engine, and develops 80 amperes at 650 volts. It is possible, therefore, to run all the eight arc light series circuits upon either of these machines. These continuous-current machines are wound with wire on the field coils, and with tape-insulated bars on the armatures, the bars being joined by curved end connections, insulated with tape and mica. The armature windings are held in place

Digitized by Google

and driven by wooden pegs, and are secured to a charcoal iron disc core by insulated circumferential bands.

Switchboards.—Erected upon the platform formed by widening the gallery immediately over the condensing annexe, is an imposing array of well-equipped switchboards, extending in all 42ft. 6in. in length. To the extreme right, when facing the boards, is the positive exciter board; next to this is the arc-light dynamo board; beside this again the arc-light circuit board. These together occupy 11ft. in length and stand 6ft. 6in. high. To the left of this set of boards is the switchboard for the general supply. This consists of a feeder board for 17 feeders, arranged in panels along a length of 21ft. and an alternator board, arranged in panels for the existing five machines, together with a synchronising board communicating with an artificial load. These last occupy 9ft. in length. The feeder and alternator boards are 7ft. in height. Details of all these switchboards are given in Fig. 5. The system of mains laid down for the general supply necessitates the paralleling of the alternators. This operation is carried out very quickly at Bristol, and without the use of the artificial load, by means of an arrangement devised by Mr. Faraday Proctor. The method consists in the insertion of choking coils between the two machines which are to be paralleled, the inductance of the coils being gradually switched down to zero. All the switchboard equipment has been admirably carried out by Mr. F. M. Newton, of Taunton.

Arc Lighting and Supply Mains.—The high-pressure feeders are of Siemens' concentric, lead-covered, double-steel-armoured cable. These cables are laid chiefly under the foot pavements, and are protected by a continuous covering of brick, and then covered over with earth and the ordinary paving. Originally the feeders were led to sub-stations in hired cellars, &c., but the more recent sub-stations have been placed beneath the foot pavements. The distributing mains are arranged on the three-wire 210 and 105 volt network system, and are of triple-concentric, lead-covered, double-steel-armoured cable. The low-pressure mains are laid in the same manner as the feeders, and are in general placed in the same trenches.

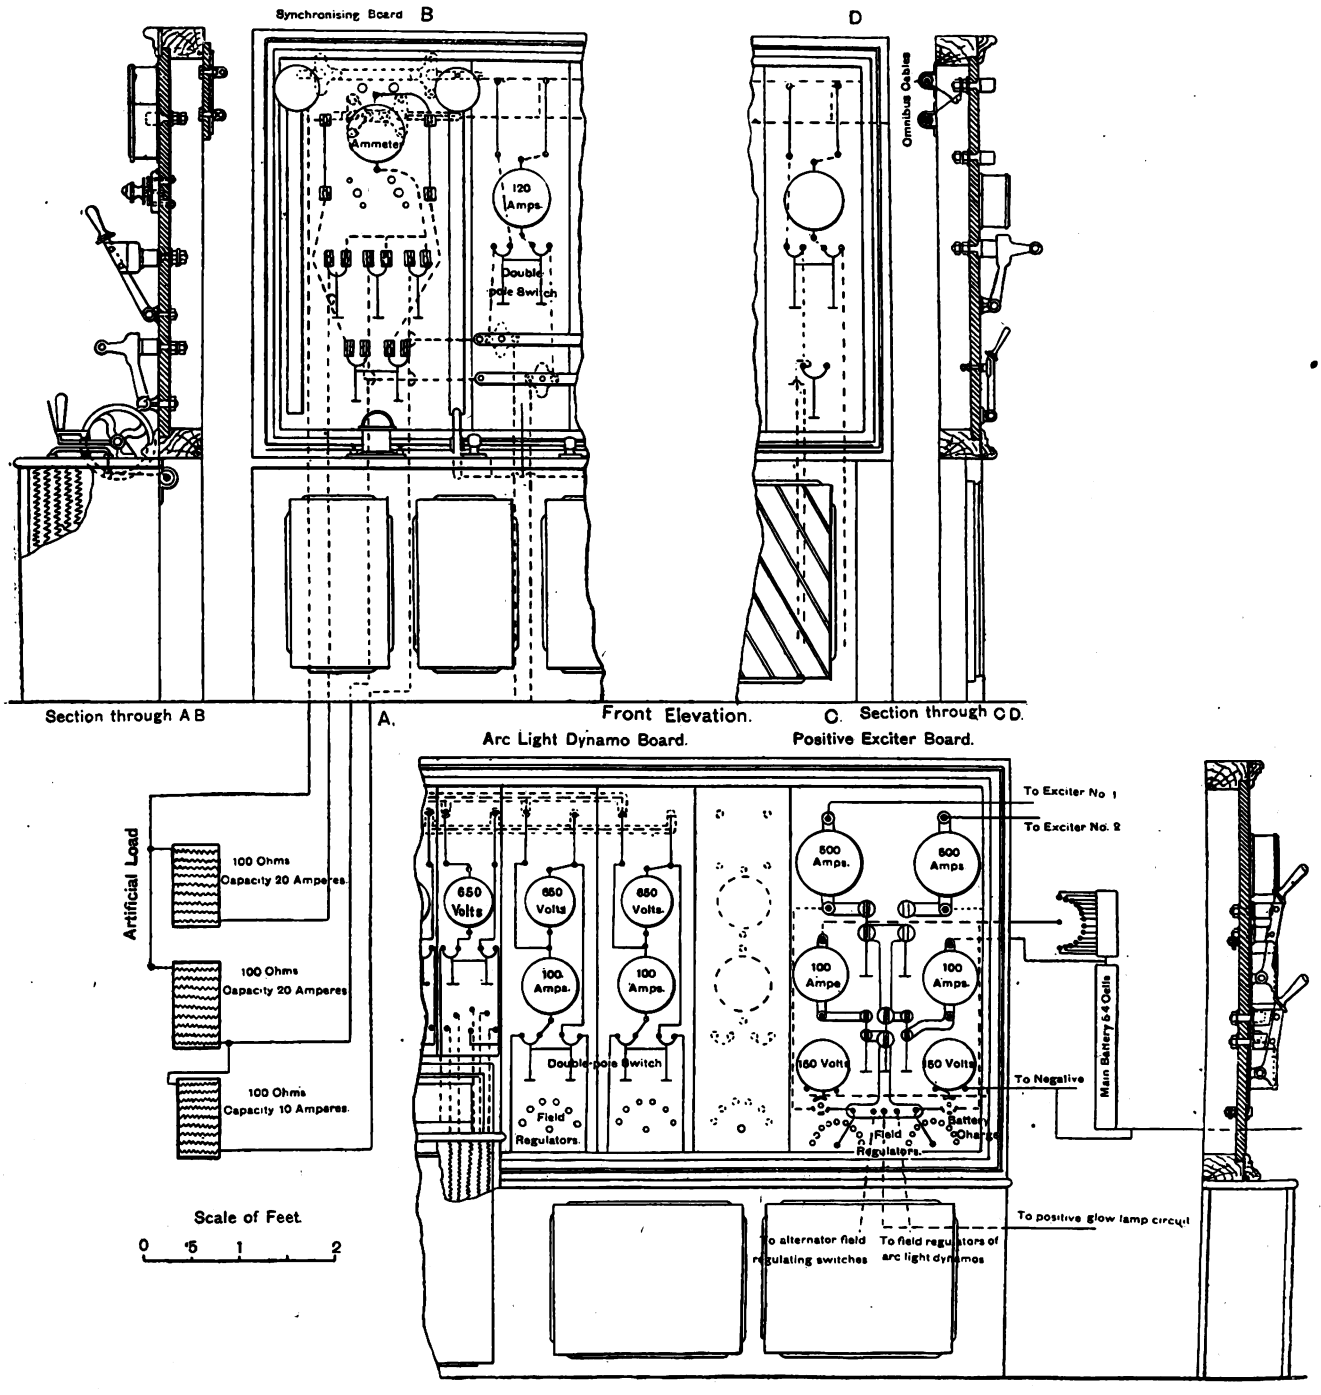

FIG. 5.—Bristol Municipal Electric Supply Station. Details of Alternator, Feeder, Exciter and Arc-Light Switchboards.

Digitized by Google

The following are some further details of the sizes and manufacture of the cables, all of which Messrs. Siemens Bros. and Co. have supplied. The high-pressure feeders are in three sizes, of 0·05, 0·075 and 0·10 sq. in. section of conductor respectively. All three are manufactured in the same way, as follows: the inner conductor consists of five strands; surrounding this is an insulation of jute treated with insulating material, in which two test or pilot wires

The low-pressure distributors are of similar construction, but are arranged in triple-concentric for the three-wire system. The section of copper is 0·15 sq. in., and there are no pilot wires. Between the outer and second circle of conductors, the layers of insulation are the same as between the second and the inner conductors, and the same, too, as the insulation between inner and outer of the feeders. A somewhat different construction is adopted in the house service mains, which are

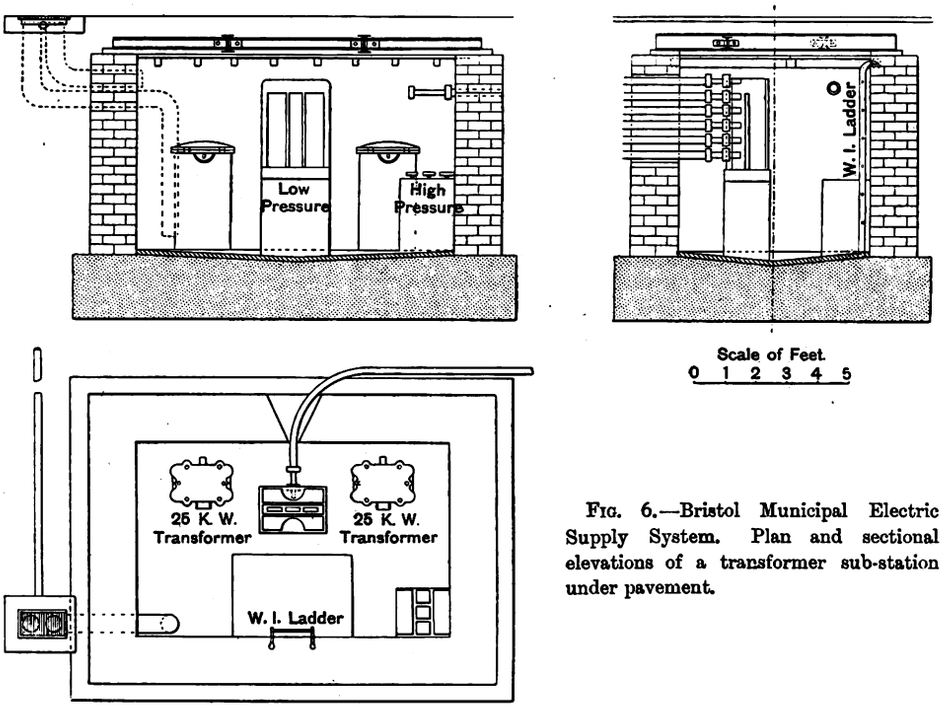

FIG. 6.—Bristol Municipal Electric Supply System. Plan and sectional elevations of a transformer sub-station under pavement.

are embedded. Around this insulation the outer conductors are equally spaced in a circle, together with the return test wire, over these comes another layer of insulating jute, over this a seamless tube of wrought-lead is hydraulically pressed at a pressure of 6,000lb. per sq. in. Then comes a serving of soft fibrous material to act as a bed or cushion for

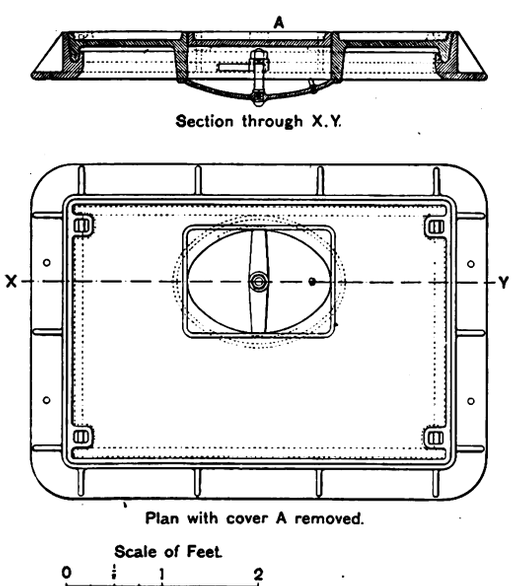

FIG. 7.—Bristol Municipal Electric Supply System. Cover used for transformer sub-station under pavement, showing smaller cover to manhole.

the steel hoops; upon this cushion two layers of steel hoops, arranged to break joint, are laid; over the outer hoop comes a layer of jute overlaid with insulating compound. The lead tube is produced from a solid cylinder of cold lead.

made in sizes to suit the customers. All these are constructed as follows:—The positive and negative cables are stranded, and embedded separately in rubber; the two are then embedded together in jute, treated with insulating material; over this a tube of lead is wrought, this being covered with jute and compound. There is no steel armour in these cables.

Two forms of arc lamp cables are used, one for burying and the other for running up the lamp posts. The buried cable consists of a single stranded conductor of 0·023 sq. in. section, embedded in jute treated with insulating material; over which comes a layer of wrought lead, covered with a bedding, and then steel stranded wire armour, over which are jute and compound. The cables carried up the posts are not armoured, and consist of forward and return stranded conductors, placed side by side in a matrix of jute treated with insulating material, over which a lead covering is wrought, this latter being covered with jute and compound.

Sub-Stations.—As previously stated, the original sub-stations consisted of hired cellars and such-like places; but this plan proving expensive and unnecessary, later sub-stations have all been built in excavations beneath the foot pavements. Details of one of these latter sub-stations are shown in Figs. 6 and 7. The former of these plans and sections of a 50 kilowatt sub-station, fitted with two Brush 25 kilowatt transformers and high and low pressure switch-boards. Since the lamentable fatality at one of these sub-stations all the high-pressure terminals and switches have been boxed in with easily removed frames of timber. The ventilation of sub-stations beneath pavements is a matter of importance. At Bristol this is carried out in the manner shown in Fig. 6, where it will be seen that two 6in. iron drain pipes communicate between the upper and lower parts of the vault respectively and a ventilated foot-plate in the pavement. This foot-plate is partly in the form of a perforated grid and partly—*i.e.*, directly over the pipes—of blind plate; and the ends of the pipes project sufficiently to prevent water from entering the vault through the pipes. Any water which

Digitized by Google

may accumulate beneath the foot-plate will be trapped into the sewers. Fig. 7 shows the form of cover used in these sub-stations. It consists of a large frame for the main cover, containing a smaller frame to serve as a man-hole. The larger frame will only be removed in the event of plant having to be taken into or out of the vault. These covers are, of course, made perfectly water-tight. Recently, one of the sub-stations at Clifton has been converted into an intermediate sub-station, from which five branch feeders radiate to five other sub-stations; and it is intended to adopt this plan of having branched feeders in other parts of the system.

Arc Lighting System.—There are at present 108 arc lamps in the arc-light system, and these are grouped as follows:—Eight series circuits, each composed of 12 Brockie-Pell double-carbon lamps, manufactured by Messrs. Johnson and Phillips; and 12 alternating arcs run in series of two or four on the low-pressure three-wire mains. Of the continuous-current arcs, five are now used in the station. The street circuits are arranged in duplicate, in such a manner that if one circuit temporarily fails, only the alternate lamps will be extinguished. By an automatic device, also, it is arranged that when the series-arc circuits are switched on, in the

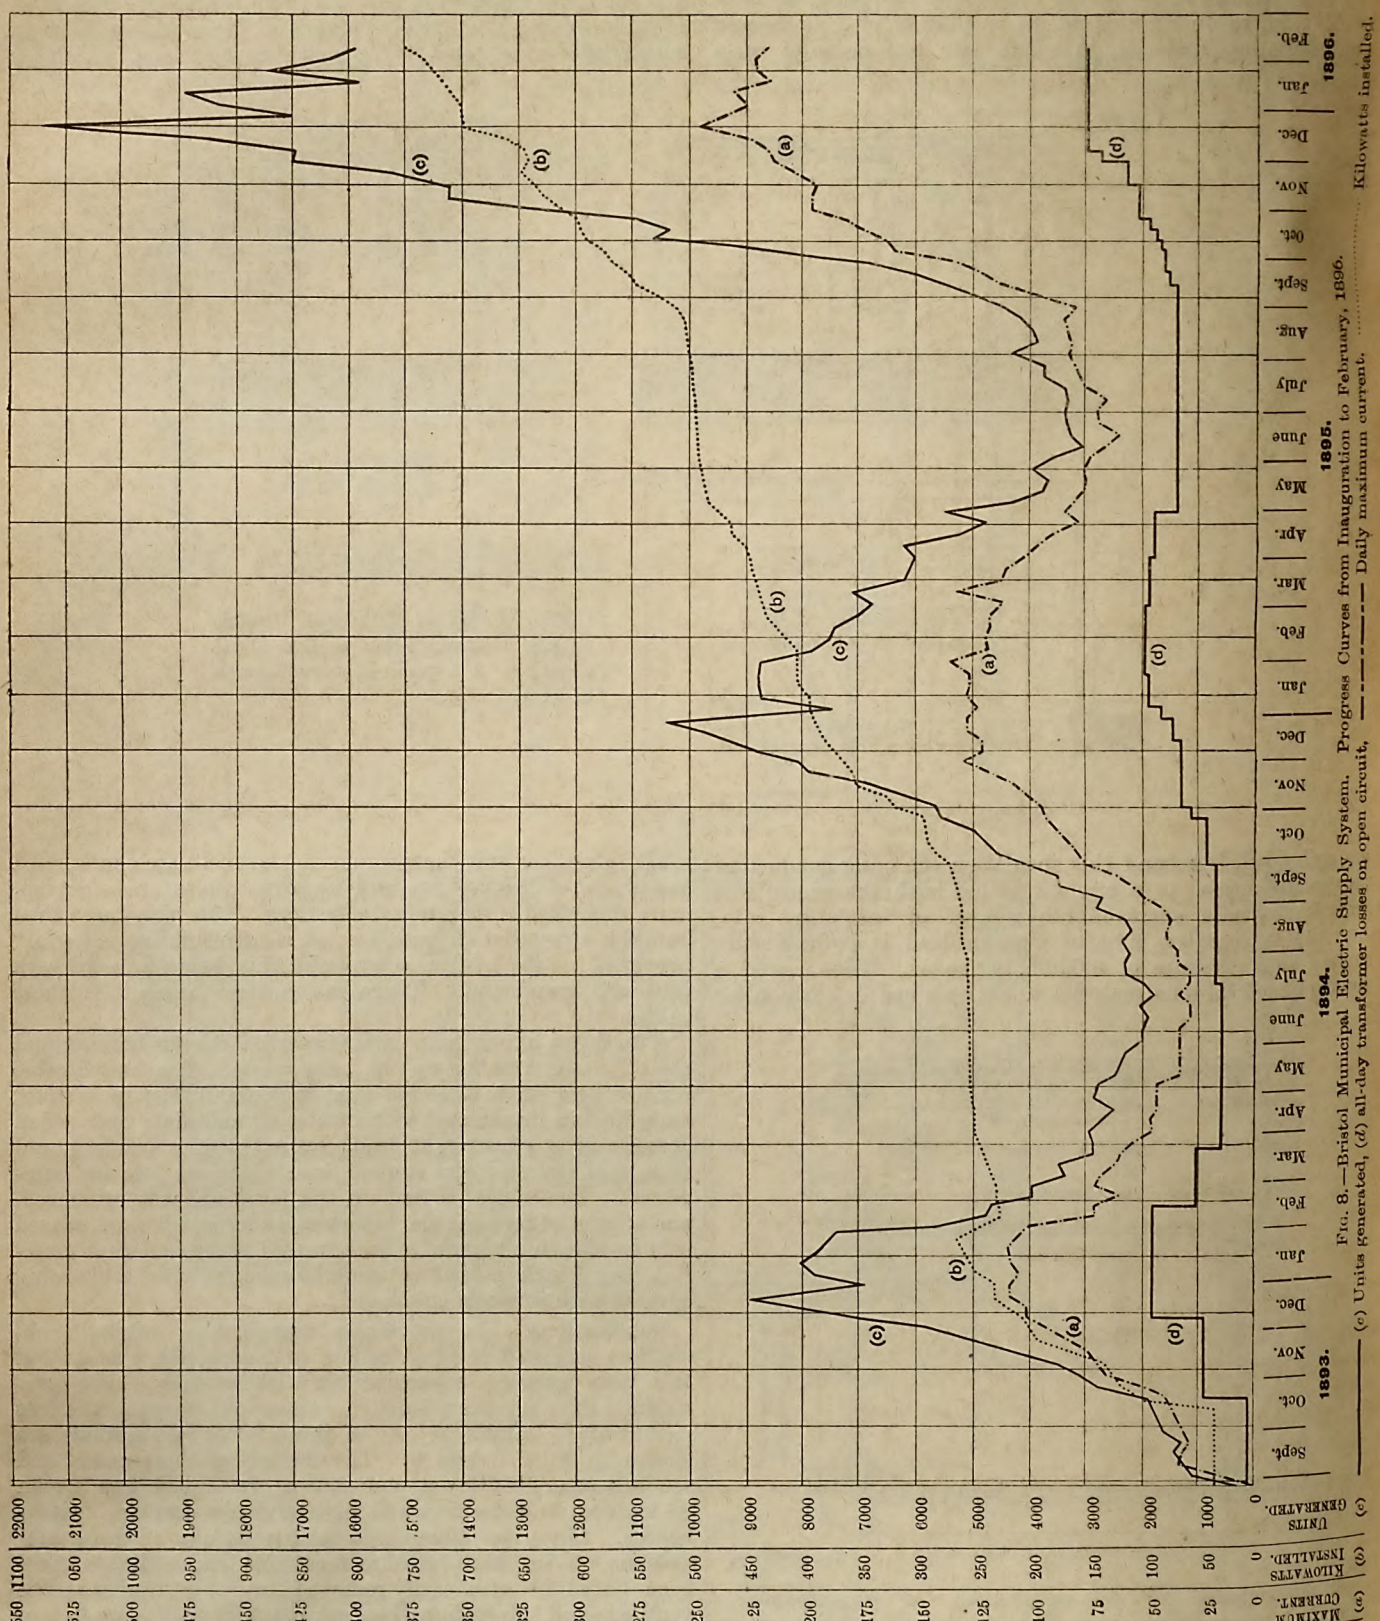

FIG. 8.—Bristol Municipal Electric Supply System. Progress Curves from Inauguration to February, 1896.

Digitized by Google

evening, those street lamps which are on the low-pressure mains shall be automatically turned on at the same moment. The lamps are carried on massive and artistic cast-iron posts, arranged in some places in the centre of the streets, but generally along the side-walks. The street lighting appears to be very efficiently carried out and to give satisfaction.

Progress since Starting.

Progress Curves.—We will now resume our study of the history of the Bristol electric supply system, taking it up at the point at which we left off—the commencement of supply. The set of Progress Curves in Fig. 8 indicates the variations of the chief items of electrical importance, from the end of August, 1893, to February 2, 1896. These curves show the following items: Curve *a*, the daily maximum current; curve *b*, the total plant installed, including lamps, motors, &c., in kilowatts; curve *c*, the daily units generated; and the rectangular stepped curve *d*, the open circuit transformer losses—*i.e.*, the all-day losses in the transformers connected to the feeders when there is no secondary current in the distributing mains. In regard to this last-named matter, it is curious that Mr. Faraday Proctor finds that this open circuit loss in the transformers very closely equals the actual total distribution loss; so that if the ordinates of curve *d*, in Fig. 8, are deducted from the corresponding ordinates of curve *c*, the difference curve will be a curve of units supplied to the consumers. It should be stated that from this set of curves (Fig. 8) the arc lighting operations are excluded; they relate only to the alternate current supply. We cannot refrain from congratulating Mr. Proctor and the Bristol authorities on the excellent progress which this set of curves indicates; but, beyond this, comment on the curves would be superfluous, as they so clearly show on the face of them what they have to teach. Perhaps, however, there is just one little point which needs elucidation, namely, that the extraordinarily high and brief peak in the curve of "units generated" in December, 1895, was produced by the short run of a pantomime. Probably, though, an expert would have guessed as much.

Daily Records.—In order to understand how the data for the Progress Curves are obtained, we must look a little into the daily routine of work at the Bristol station. On page 622 there is reproduced in type the daily log for Thursday, January 2, 1896, a sheet which is typical of the log-sheet filled in at the station every day. A close inspection of this sheet will afford considerable useful information. The blank log-sheet is a printed form, on the back of which are faint square rulings for plotting the load diagram of the corresponding day. The switchboard attendants fill in the instrument readings every half-hour, and mark with a cross to indicate the boilers which are giving steam; and the particulars of any change in the working plant, of a breakdown, or any incident of importance are recorded in the "Remarks" column. At the end of the day the quantities registered in the space at the bottom of the sheet are worked out and entered, these quantities comprising:—(1) the total hours run, total units, amount and time of the maximum current, total ammeter readings and average load of the alternators and feeder circuits; (2) the total ammeter readings, average load, total hours run and total units generated for the arc light circuits; (3) the ampere-hours' charge, the ampere-hours' discharge, and the difference between charge and discharge of the battery; (4) the in-take and consumption of gas, coal and oil; and (5) the total output of the station, in units, for the week ending at the end of that day.

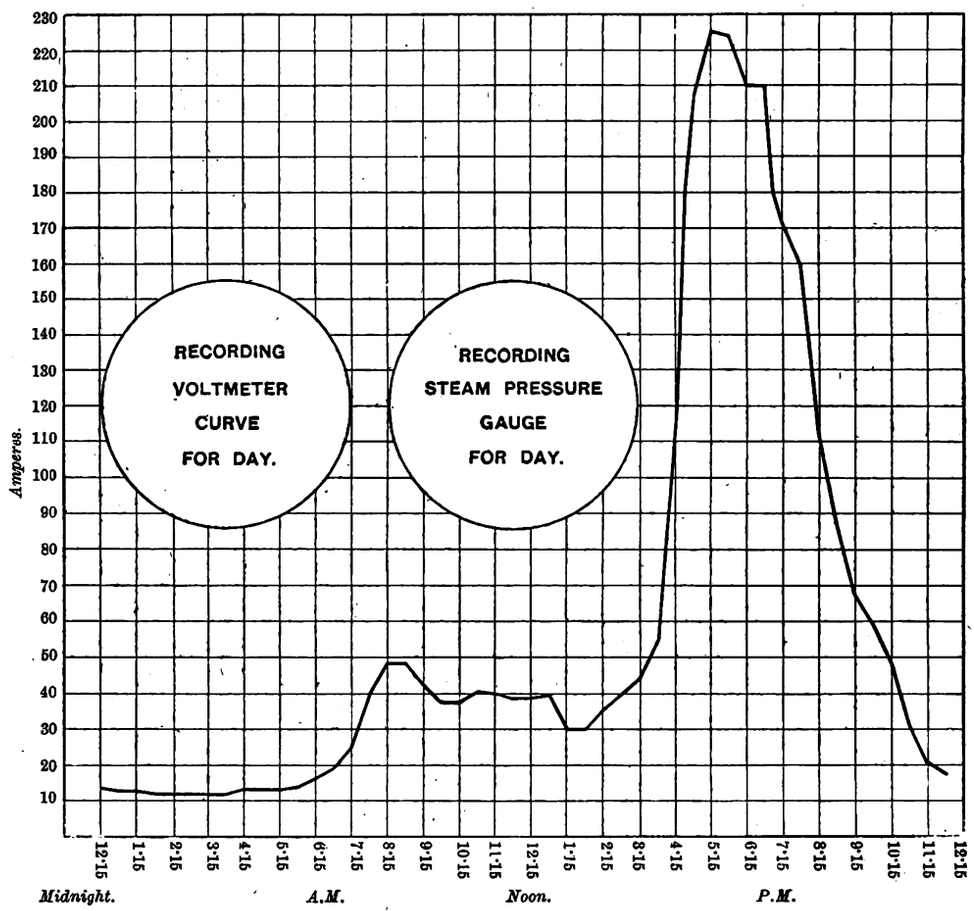

FIG. 9.—Bristol Electric Supply System. Load Curve for Thursday, January 2, 1896.

Load Diagrams.—It will be seen that the "total amperes" readings for the alternate-current supply are entered in the first column, annexed to the "time" readings. This is to facilitate the plotting of the load diagram for the day, which is done in the following way:—The first two columns of the log sheet are folded back, so as to appear on the back of the sheet. This back is ruled in squares, and has a scale of "time" printed on its base and a scale of "current" printed vertically from the zero point. The two columns of figures folded back will be seen at the extreme right, and thus will make it easy to plot the load diagram for the day. When this has been done the day's sheets from the recording station

voltmeter and recording steam pressure gauge are stuck upon it. The finished load diagram for January 2, 1896, is shown in Fig. 9. The recording voltmeter and steam pressure gauge are of the "Bristol" type.

Extension of Mains.—The greater part of the extension of the Bristol system has taken place in the mains laid. This item of development is shown in detail in the accompanying map of the area supplied (Fig. 1).

Financial Progress.—Finally, we have to consider the progress of the Bristol electric supply system from a financial point of view. We have stated that the concern commenced work saddled with a total expenditure of £80,000, as against an originally estimated cost of £60,000, with £6,000 for contingencies. The succession of unforeseen events, such as the discovery of the rotten nature of the ground on the site, and the increasing magnitude of the scheme, no doubt account for much if not for all of the difference. We have also seen that from the outset the concern has been saddled with heavy charges for rates and taxes, an item which for the year 1894 amounted to 1·18 pence per unit sold, and which exceeded the outlay on salaries, wages, repairs and maintenance, and almost equalled the total cost of coal for the year. So large an assessment must be a burdensome standing charge upon the concern; and we have only to compare Bristol, in this respect, with Brighton or Manchester, to see how much more

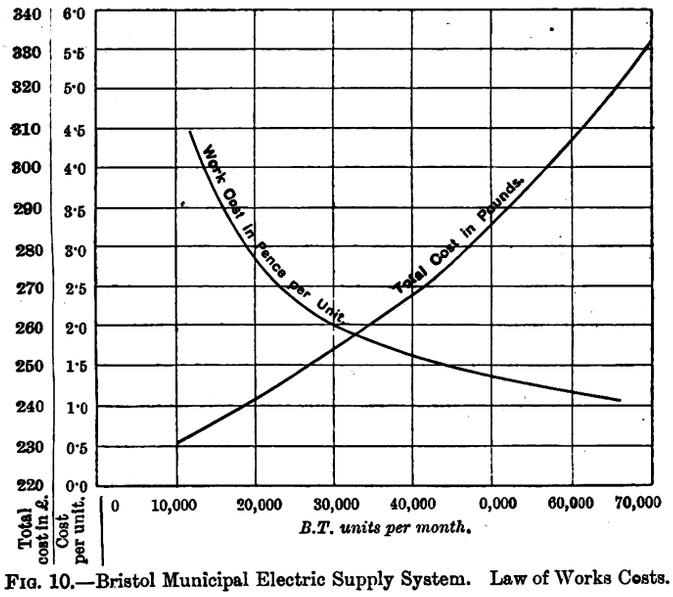

FIG. 10.—Bristol Municipal Electric Supply System. Law of Works Costs.

fortunate other municipal concerns are. At Brighton, the total charge for "rent, rates and taxes" was only £165 on a total capital outlay of £119,382, of which £44,918 had been expended on buildings, lands and plant. The capital account for Bristol, up to December 31, 1895, is set forth in Table III.; in Table IV. the outputs for 1894 and 1895 are analysed; and in Table V. the revenue accounts for 1894 are given in detail.

Law of Works Costs.—During the year 1895 Mr. Proctor analysed the works costs, with a view to obtaining some sort of law connecting the monthly output with the total cost and with the cost per unit generated. The curves showing the relations between these three quantities, for the Bristol system, are given in Fig. 10.

Table III.—*Capital Expenditure to December 31, 1895.*

——	To Dec. 31, 1894.	To Dec. 31, 1895.
Amount sanctioned	£90,000	...
Total capital received	90,000	£100,000
„ „ expended	82,186	97,794
Capital expended in lands and buildings	26,609	26,668
„ „ „ plant	30,796	33,267
„ „ „ mains	18,442	29,754
„ „ „ meters	1,236	2,422
„ „ „ public lamps	3,538	3,538
„ „ „ miscellaneous items	1,560	2,145
Total capital expenditure per Board of Trade unit sold	5.59s.	4.85s.

Table IV.—*Analysis of Output for 1894 and 1895.*

——	1894.	1895.
Total B.O.T. units supplied during year	293,523	408,301
B.O.T. units supplied for general use during year.	143,106	251,708
B.O.T. units supplied for public lighting during year	150,417	156,593
Price per unit during year	4d. & 6d.	4d. & 6d.

Table V.—*Analysis of Revenue Accounts for year ending December 31, 1894.*

——	Total in £.	Per unit sold in pence. *
Receipts during year	6,624	5·42
Expenditure during year	6,168	5·04
Item: Generating expenses	3,177	2·59
„ Distribution expenses	79	0·06
„ Management expenses	880	0·71
„ Rent, rates and taxes	1,453	1·18
„ Attendance, repairs, carbons and renewals of public lamps	579	0·48
„ Coal	1,560	1·27
„ Oil, waste, &c.	186	0·15
„ Salaries and wages	1,156	0·94
„ Repairs and maintenance	275	0·22

* This includes the units supplied to the City for public lighting.

At the present date the accounts for the year ending December 31, 1895, have not yet been published in detailed form. It is therefore impossible to give an exact analysis of the revenue accounts for that year. We are, however, in a position to state that there has been a gross profit of £4,019 19s. 10d. for the year 1895; as against a gross profit of only £456 7s. 11d. for the previous year. On the other hand a sum of £4,557. 11s. 9d. has been obtained from the General District rate. The total cost of the public lighting for the twelve months ending December 31, 1895, was £3,447 3s. 10d., including attendance, repairs of lamps, carbons and the supply of power.

Conclusion.—In conclusion, we desire to express our great indebtedness and thanks to Mr. Faraday Proctor, the resident and consulting electrical engineer to the Bristol municipal authorities, for the courtesy he has extended to us, in supplying us with particulars of the large and interesting concern under his charge. Our thanks are also extended to Mr. Palgrave Simpson, of Messrs. Siemens Bros. and Co., for supplying us with particulars of the alternators, continuous current machines and cables, which were made by his firm.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-day) FRIDAY, March 6th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Students' Meeting in the Library of the Institution. Paper to be read: "A Simple Method of Analysing Harmonic Curves," by E. Basil Wedmore.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "The Tunnel under the Thames at Blackwall," by A. R. Binnie.

INTERNATIONAL HORSE AND HORSELESS CARRIAGE AND ROADS LOCOMOTION EXHIBITION.

3 p.m. Meeting of the Honorary Council of Advice at the Mansion House.

SATURDAY, March 7th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "Light," by the Right Hon. Lord Rayleigh, F.R.S.

MONDAY, March 9th.

NORTHERN SOCIETY OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting at the Palatine Hotel, Hunt's Bank, Manchester. Adjourned discussion on "The Paralleling of Alternators," by R. Hammond.

TUESDAY, March 10th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Mr. W. H. Wheeler's Paper of last week will be further discussed, and, time permitting, three Papers dealing with Metallurgy will be read.

THURSDAY, March 12th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary Meeting. Discussion on "High Voltage Lamps and their Influence on Central Station Practice," by G. L. Addenbrooke.

STEEL-PLATE PORTRAITS

Of Willoughby Smith (out of print); W. H. Preece, C.B., F.R.S. (President of the Institution of Electrical Engineers); Michael Faraday (1s. extra); Sir John Pender, G.C.M.G., M.P.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Patey, C.B.; Dr. John Hopkinson, F.R.S.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz; Prof. W. E. Ayrton; Lord Rayleigh, F.R.S.; Cyrus W. Field; Werner von Siemens; Sir James Anderson; Joseph Wilson Swan; Mr. Alexander Siemens; Dr. Heinrich Hertz; Mr. R. E. B. Crompton; and William Sturgeon have been issued as Supplements to "THE ELECTRICIAN."

Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price 4s. 6d., carriage paid (U.K.)

HOUSE WIRING.

The discussion on Messrs. SAM MAVOR and FRED BATHURST's Papers on "House Wiring" no doubt suffered seriously from the long interval that elapsed between the date of their reading and the first night of their discussion. The majority of members were indifferent to the merits of interior conduits as practised in the United States of America and the Continent, and cared little about a system of concentric wiring which was inapplicable to the great majority of installations owing to Board of Trade restrictions. And, perhaps, the fact that both systems as described in the Papers were covered by patents tended largely to destroy a general interest. Viewed broadly, however, the discussion shows that there is a growing dissatisfaction with wood casing, and that there is a decided tendency to use conduits, preferably pipes, wherever the nature of the work and the price obtainable admit of it. This is chiefly due to a desire to conceal the wiring in a safe and permanent manner. It is obvious that iron pipes can be laid in plaster, beneath floor-boards or behind wainscoting with the same freedom from accidental damage as is the case with gas and water pipes. The same cannot be said for wood casing as ordinarily used. In new buildings it is obviously desirable to conceal the wiring, and hence wood casing, which has done yeoman service in the introduction of electric lighting, bids fair to gradually sink into desuetude. Yet it will die hard. Its erection does not require much skill, and carpenters and joiners are "as plenty as blackberries." Wood casing is, therefore, in most instances the cheapest class of work, and neither interior conduits nor concentric wiring are likely to supersede it for the general run of work until they can compete with it in the prime essential of low first cost. And this, as Mr. G. BINSWANGER pointed out, depends largely on the demand. Economy, in spite of fire insurance offices and patented systems of safety wiring, is the crux of the whole matter. Do either of the systems advanced offer any striking advantage in

Digitized by Google

this respect? Interior conduits without substantial armour do not commend themselves to the leading fire offices unless treated precisely like wood casing as regards the separation of the wires, and this at once rules the system out of court on the count of expense. Armoured interior conduits are evidently more expensive than plain iron tubes, both on account of the cost of lining them, and also because the outer tube must be of greater section. Mr. BATHURST's proposal to divide the insulation between the wiring and the tube appears to us to be a step in the wrong direction. It lessens the insulation between wire and wire, and probably also between copper and earth, and does not provide sufficient protection against moisture. It appears to us that insulation is most effective around the conductor, and can there be most cheaply applied. Of course, special care is necessary with bare iron pipes. They require to be reamed out and painted inside; the mouths should be bushed with insulating material, and precautions may sometimes have to be taken against condensation of moisture. Judging, however, from a large number of installations erected by various firms, and carried out according to their own plans, and thus subject to no patent royalties or similar limitations, it would appear that iron pipe work is a success, and that its use is extending. Mr. ADDENBROOKE's proposal to use iron pipes with a single insulated wire, the pipe forming the return, may become an accomplished fact before long. Mr. CROMPTON almost prophesied so. This plan has been tried in places where neither Board of Trade nor fire office regulations applied, but with doubtful success, owing to the difficulty of keeping the resistance of the joints sufficiently low, but the material used was unsuitable. When the middle wire of a low-pressure distribution system may be earthed at the feeding points (as most of us wish they might), there should be no real difficulty in the way of the iron-pipe return other than the competition of Mr. MAVOR's concentric system.

From an engineering point of view there is much to commend concentric wiring as originally introduced by Mr. J. D. F. ANDREWS, and since modified by Messrs. MAVOR and COULSON and others. That it has not found more favour is perhaps due chiefly to the Board of Trade restrictions which, even now that the middle wire may be earthed at the station end, practically prevent the use of an earthed outer on premises supplied from a central station network. It is to be regretted that the new regulations do not give a fair field to concentric wiring and enable it to take its place on its merits. It seems to offer certain advantages on account of simplicity and of the standard patterns which have been devised by the owners of the patents, and although we do not think their fittings and details to be such as are likely to be finally adopted when the system is more generally understood, yet they make for sound work at a minimum cost. Mr. ANDREWS estimated the reduction of cost of interior wiring at from 20 per cent. to 30 per cent. below that of wood-casing a conductor. This is a sufficient economy to make electric lighting possible in many cases where the initial cost of installation is at present prohibitory.

The policy of the fire insurance offices was criticised from different points of view. Major Gen. WEBBER and others contended that the "Rules" were unnecessarily severe, while Mr. SAM MAVOR considered them none too stringent for double wiring in wood casing. Some uncomplimentary opinions were advanced by speakers who apparently forgot that the offices deal with averages and take the risk at the option of the insured, and hence have a definite right to make their own terms. Moreover, the "Rules" have never pressed unduly on sound conscientious work, and have certainly been instrumental in placing a limit on jerry work in buildings over which the Board of Trade has no control.

The latest new thing, the 200-volt supply, did not meet with universal approval, and Mr. GEIPEL went so far as to urge wiring contractors to combine with consumers in emphatic protest against the practice. There is unintentional irony in this suggestion, which the cheap wiremen will no doubt appreciate; for the higher pressure will undoubtedly find out defective work which will just pass muster with the present standard of 100 volts. The futility of so-called insulation tests is well recognised even by the fire offices, but the automatic continuous test of a 200-volt current will soon break down shoddy work.

Mr. FRED. BATHURST certainly made an excellent reply on behalf of his interior conduits, and although we cannot agree with him that the system is the only one which makes for "safety, durability, convenience, accessibility and economy," we concur with much that he said. We are fully of opinion that before electric light can be generally used it must compete with gas, not only as to cost light for light, but also as to cost of installation. To fulfil this latter condition Mr. BATHURST boldly proposes to use a cheap class of twin-wiring which, with an unarmoured insulating conduit, costs, he says, no more than the wire in an ordinary job. He thus hopes to save the price of the wood casing, as well as part of the labour of erection. If the insulated interior conduit really prove as cheap and convenient as its advocates assure us it will, the system is bound to make its way to the front, and Mr. BATHURST may therefore rest content and cheerfully await events, notwithstanding the prejudices of fire offices, the official frowns of the Board of Trade, and the academic criticisms of all who do not see eye to eye with him in this matter. Time and trial will soon teach us the truth.

REVIEWS.

Applied Magnetism: an Introduction to the Design of Electromagnetic Apparatus. By J. A. KINGDON, B.A. (London: Alabaster, Gatehouse and Co.)

It is to be hoped that the time is not far distant when the fundamental theory and equations of the magnetic circuit will be as much a part of the preliminary training of the young electrical engineer as the corresponding equations of the electric circuit. When he reaches the subject of dynamo-electric machinery he should bring to its study a familiar acquaintance, not only with Ohm's law, but also with its magnetic analogue, and a power of applying the latter as automatically as the former. The pages of the text-book on dynamos would then be relieved of the inevitable elementary chapters on "lines of force" and "magnetic fields," and the author could assume that a knowledge of ampere-turns, flux and reluctance is as much a matter of course as of volts, amperes and ohms. The first title of the present book, "Applied Magnetism," leads one to expect a manual dealing with the theory and design of magnets in such a manner as would pave the way for a treatise dealing more specially with dynamos and transformers, in which applied electricity is combined equally with applied magnetism. Some such purpose seems to have been present in the mind of Mr. Kingdon, but to our thinking he has either not confined himself sufficiently closely to the subject of magnetism, or has given to his book a title which is somewhat of a misnomer. The opening chapters deal with the elementary facts and theory of the magnetic circuit, but before long we reach chapters headed "The Alternator," "The Dynamo," "Commutator and Collectors," "Electromotors." Outline sketches of these subjects are alone possible within the limits of the pages allotted to them, and thus the book comes in the end to be a preliminary treatise on dynamo-electric machinery at large. Alternators, continuous-current dynamos, motors and transformers, all alike are touched upon, their

Digitized by Google

most salient features being shortly described and summarily dismissed.

As such an introductory treatise, "Applied Magnetism" is lucidly written, and, so far as its scope permits, adequate and accurate. Indeed, the author can only be charged with the fault—if it be a fault—of excessive orthodoxy in his method and facts. Unit pole and $4\pi n c$ are again made to go through their eternal round. We are even thrown back on Ampère's man swimming with the electric current, which is surely an old-fashioned device for connecting direction of current and polarity. It is surprising that not a single *curve* connecting **B** and **H** for different classes of iron and steel is given; tabulated data alone appear, and Dr. Hopkinson's figures for annealed wrought iron and grey cast iron are again made to do service, although the advances of modern metallurgy are usually regarded as enabling the manufacturer to better the results of 1886. We cannot congratulate Mr. Kingdon on his adherence to his own peculiar name of "mags" for C.G.S. lines. Since a mag is nothing more or less than a C.G.S. line, what advantage is gained by the substitution of one monosyllable for another? By the adoption of rational units we had hoped to see the author solve the mag – π question, but so far from this, the whole book only illustrates the irrationality of the present system, since almost every magnetic formula contains a cumbrous constant of 1·257.

The elementary theory of the dynamo and motor is clearly set forth, and the chapter which gives the theory of non-sparking commutation appears to us a distinct advance on the ordinary text-book treatment. The short-circuited coil is not separated from the rest of the armature, and regarded by itself as possessing energy stored up in it by virtue of its self-induction. The armature and magnet are treated as a whole, and it is shown that the magnetic effect which would be due to the simple mechanical rotation must be balanced by the magnetic effect due to the changing current, so that the total flux remains constant if sparking is to be avoided. The statement that the devices of stranding or laminating the bars of large armatures are so effectual in preventing eddy currents that "the armature loss is practically only the $C^2 R$ loss" is open to question. No mention is made of the fact that as regards hysteresis the rotation of the armature core of a continuous-current dynamo in a steady field is not precisely analogous to the alternating magnetic flux of a transformer, and that there are good grounds for caution in transferring experimental results from the one case to the other.

Appendices in which the units and formulæ employed are tabulated, and a good index, add not a little to the usefulness of the book, while a final word of praise should be given to it on the score of its clear arrangement of paragraphs, good type and excellent printing.

HOUSE-WIRING.

CONCLUDING DISCUSSION ON THE PAPERS READ BY MESSRS. FRED. BATHURST AND SAM MAVOR BEFORE THE INSTITUTION OF ELECTRICAL ENGINEERS.

Speakers who have revised the abstracts of their remarks have asterisks placed against their names.

THURSDAY, FEBRUARY 27TH.

*Mr. G. BINSWANGER said he wished to add a few words to the discussion as to the manner in which this subject struck him as a manufacturer. The question whether this or that system of wiring should be adopted for any particular installation was a question to be decided by the contractor. Manufacturers had to find out what demand there was likely to arise. He came into contact with a good many contractors, and he found a general concensus of opinion that wiring in wood-casing must be some day or other superseded. It certainly was not a system which recommended itself to the fancy of an engineer or an architect. He had also found amongst contractors an idea that the fire insurance offices, and especially the Phœnix office, recommended, or even insisted upon the adoption of wood-casing. He might say that such an idea was erroneous. Mr. Heaphy had passed wood-casing because, as he had often told him (the speaker), from his point of view he had never had a failure, he had never had a fire to record; but if any system could be proposed which gave the same security—and, after all, the consideration of fire risk was the first which they had to study—and if such a system should present advantages to the engineer and to the architect, he was sure Mr. Heaphy would be one of the foremost to recommend its adoption. Contractors often asked him the question whether, if they adopted any of the new systems proposed, they would be able to obtain the materials required readily and at reasonable cost. His answer was that of course the question of supply depended upon the demand; the larger the demand the more ready the supply. As to cost, that must depend, and did depend, to his mind, largely upon the contractor himself. If he enabled manufacturers to lay down a plant to manufacture cheaply, no doubt the cost of the material would be low. The material required for wood casing had had an enormous sale for the last ten years, and naturally the cost of such material was at present very low. To compare therefore, the cost of installations of the new methods proposed with that of the old methods was to his mind unfair to the new methods. There was another question, that of standardising. Let them at the very beginning of a new system fix on standards. Every article should be standardised by a competent authority, and every contractor could use nothing else. What struck him most in Mr. Mavor's very excellent Paper was his successful attempt at standardising. The same might be said of Mr. Bathurst's system, which also lent itself very well to being standardised from beginning to end. He was inclined to suggest that some committee should be appointed by the Institution to give them some standards, which he believed every manufacturer in England would be glad to adopt.

*Mr. H. BOOT said so far as the discussion had gone very few speakers seemed to have realised the importance of the question at issue. They might say, whether central station engineers, manufacturers or whatever they were, that everything depended upon this one question. It often happened that at the same time they were obtaining an estimate for wiring for electric lighting people got an estimate for fitting with gas, and when the two costs were compared the difference was simply ridiculous. Unless they adopted some system whereby they could reduce everything to the lowest cost, especially for point wiring, he did not think that there was any good in introducing further systems. What they really required was a system that could be put up by any ironmonger of repute. It was a question very much of labour in all these jobs. If they looked critically at the cost of wiring they would find it came out that it was carpenters, joiners, and wiremen that cost the money, and not the actual material. If they reduced this labour and made the matter so simple that any intelligent man could put up an installation, they would be doing a great thing for the electrical industry as a whole. A great number of members seemed to be under the impression that electrical wiring and contracting business should be undertaken only by firms of great repute. This was natural, and was the case in the early days of the gas industry. The tubular system undoubtedly came out dearer because it had not been generally adopted, but if it were long on the market it would probably come out cheaper than the present method of wiring. With regard to Mr. Mavor's system, his experience tended to show that the fittings were rather expensive, and required a special class of labour; he was rather surprised, therefore, that Mr. Mavor should claim cheapness for his system. If the readers of the Papers had given a few more particulars as to how the cost was made up, how much was allowed for labour, how much for holders and various other items, they would have been able to judge better and compare with the present systems.

*Mr. W. R. RAWLINGS said he would like to point out a defect in the tubular system as exhibited by Mr. Bathurst. The tubes themselves were not flexible. It was of no use saying they could do without a flexible tube, because contractors were asked to place wires behind valuable cornices, which they were not allowed to cut, and unless the tube was flexible it would not answer in that case the purpose for which it was required. Another important point was that, where it was buried beneath plaster, the wiring should be nail-proof. While on the subject of insulation tests, he should like to state that he considered that the unit was some what of a myth. It was, he thought, the duty of the Institution to stamp out the workmen who were going about, the scum of other trades, who called themselves wiremen. He understood that the City and Guilds of London Institute was doing something in this direction; but whatever they might do, if they qualified the men, they would not necessarily make them honest, and it was honesty of purpose they wanted in their men. A few weeks ago they had on the table specimens of bad joints supposed to have been put in by a firm of repute. He had not the least doubt that that firm had every reason to believe their installation was put up rightly, for they assumed the honesty of their workmen. He would suggest that the Institution should have a method of registering the men. Let the members support the men so registered, and if necessary blackball those who did not come up to the standard of honesty.

*Mr. H. HUMAN said, when reading over the Papers under discussion, he recognised that the fire office question was bound to crop up, and that he was, therefore, in for a bad quarter of an hour. Though he would prefer to have ignored that part of the subject, he could not deny that it had been very prominent during the discussion, and was so vigorously handled by Major-Gen. Webber that it was impossible for him to do so. He might say, then, at the outset, and speaking only for himself, that he agreed with a great deal that had been said anent fire office inspections of electric installations. He admitted that many of those inspections were more or less a farce, and must necessarily be so; he would even venture to say that fully nine out of every ten of such inspections might well be dispensed with, being little else than a waste of valuable time, and wholly unjustified. Indeed, the day must come when the electrical inspector, pure and simple, of the fire office, would disappear from the scene, and his rules with him. With regard to fire office forms, again, he agreed that some of them were unnecessarily long; they attempted too much. A form is a useful thing in its way when kept within moderate limits. It serves as a record in the books of the company, and further enables one to judge as to whether there is any special feature calling for further attention. But a few simple questions easily put, and as easily answered should suffice. Some of those forms are very entertaining reading, and he noticed in particular that contractors have a remarkable affinity for the

Digitized by Google

word infinity when speaking of insulation. Well, he hoped they knew what they were about when using it. There is ample documentary evidence to prove, if needed, that if the Institution recommend that all tests for insulation should show infinity, there would be no difficulty on the part of contractors in meeting that little requirement. Gen. Webber appears to be very much incensed at the present rating of central stations by the fire offices, but while he (the speaker) could quite understand that gentleman's feelings in the matter, he begged him not to put the whole burden upon the one animal. When those stations first came up for consideration the fire offices regarded them very favourably, and accepted them at exceedingly low rates. The offices have now bought their experience, and paid for it dearly, for "there stands at present a large deficit against you. There is no sentiment in the matter whatever; it is purely a business transaction. We may not be interested, as you are, in the conservation of energy, but we are very much interested in the conservation of pounds, shillings and pence. We now recognise that not only have we underated those risks, but have, in consequence, undersold our indemnity, and, as business men, are simply rectifying that little error by raising our rates." Gen. Webber objected, apparently, to being tarred with the same brush as his friends. That he (the speaker) could quite understand, and sympathised with him, for it was a process which fire office surveyors too frequently experienced at the hands of engineers when dealing with electrical matters. But in Gen. Webber's case he failed to see how it could be obviated, for it must be remembered that where you legislate for a class there must be no exemption in favour of individuals. As so often happens in other matters, the good have to pay for the bad. That might be poor consolation for Gen. Webber, but it was the best he could offer him under the circumstances. As to making reductions in favour of electric lighting—particularly in such buildings as dock warehouses—he would remind Gen. Webber that the lighting was by no means the one and only thing to be feared, but that the risk in such places was inherent in the varied nature of their contents, and to allow for electric lighting in those risks would, indeed, be straining at a gnat and swallowing a camel.

Mr. J. N. SHOOLBRED said he would confine his remarks to one particular point, and that was with regard to the table of insulation tests which Mr. Bathurst had put in his Appendix B. He was very glad to see that in that table Mr. Bathurst had adopted as the basis for the test the ampere and not the lamp, as was commonly the case with several of the various sets of rules we had in use in this country.

*Mr. DYKES said at the present time the question which was the best system of electric wiring was on a par with the question, which was the best engine or boiler. It simply depended on the circumstances of the case. In fact, practically every system which had been mentioned was good in the proper place. They had heard a good deal in dispraise of wood casing, but he maintained that if proper care was taken and wood casing was put in the proper place they could make quite as good a job with it as with any other device. He had in his mind at that moment an installation where, he thought, they had a sample of pretty nearly every kind of wiring which had been mentioned. There were certain rooms having a good deal of panelling and there, naturally, one would put in wood casing to match the woodwork, and if it were properly put in and properly used he contended it was as safe any other parts of the installation. There were other parts where the wires were simply run in iron pipes coated with Angus Smith's composition, those places being conservatories, stables and so on, where it was important to have the wires thoroughly protected and where there were no decorations to be studied. In still other parts of the same installation were wires run in compo piping placed where it was impossible to be damaged by nails. The concentric system of Mr. Mavor certainly possessed considerable advantages in cases where it could be used. It did not matter what system of wiring they used, it seemed to him; the trouble was not in the wire or in the conduit system itself; it was practically always at the accessories, the switches, fuses, and so on. If they made the switches, cut-outs, wall plugs, and so on, good, they could pretty well use any system of wiring they liked, provided, as he had said, they suited the system to the place where it was to be employed. With regard to the use of iron pipes carrying insulated leads, the pipes being uninsulated, they were told by Mr. Bathurst that if they wished to use iron pipes they must insulate them inside. He (the speaker) maintained that that was entirely wrong. If they were going to use an iron pipe they should not insulate it at all. If they had leakage from their wires, then let it go direct to earth, blow the fuse, and all would be over. That meant, of course, they must break up their system, and only use comparatively small fuses; in fact, he went so far as to say they should not use anything larger than circuits to carry five or six lights. In the class of buildings which was now becoming so general for insurance offices, banks, public halls, &c., where the flooring was of wood blocks laid direct on the iron and concrete fire-proof floors, and where the walls were faced with marble, tile work, or hard plaster he was of opinion that the iron pipe system offered advantages over all others. As his firm had had some considerable experience of that system, a few particulars might perhaps be of interest. To begin with, they found that it could be put in at a cost not exceeding that of good wood casing in a similar building. The pipes were laid as the work went on, the cement floors being floated over them, thus avoiding the usual cutting away of plaster, floors, &c., and although some of the pipes might be in position months before they were covered by the floor blocks, tile work, or plaster, no damage was done and not a single yard of wire had to be replaced through being damaged by workmen. The heavy joiner's bill, too, was, of course, abolished. There was no trouble in getting a very high insulation, as high as with any other system; it only meant, as usual, that fittings, switchboards, &c., must be well insulated; until these were put up the insulation was practically infinite. As the current was generally switched on in sections, as the work was finished, it was often difficult to get a test of the installation as a whole; but he might say that a test at a City bank wired to their specification on this system gave, when tested some weeks ago, and repeated once or twice at intervals, an insulation of 1½ megohms for 135 lights. At a similar installation a section of 40 lights, tested the day before, gave only the faintest movement on the ohmmeter, which was calibrated up to 5 megohms. In both these cases the switches were let in flush with the tilework, and in the former case there was a large number of points on glazed brickwork in the cellars. At another installation in a private house, tested a week or so ago, where a mixed system was used, the total number of points was 114, there being four distributing boards, and the insulation of the whole above earth was 2·9 megohms. These figures would show that it was not at all impossible to get very high insulation by taking a few precautions, although at the same time he personally put very little trust in insulation tests. They had an iron pipe installation of about 430 lights where all switches were, as usual, sunk in the tilework, hidden by fancy metal-cover plates. In this instance switches of the "tumler" pattern were used, the flat cover plate being screwed on in place of the usual cover. With these plates off the installation tested out quite as well as the rest, but when the covers touched the tile work the leakage over the numerous switches was sufficient to bring down the insulation very considerably indeed, although still above the ordinary fire office requirements. This could be remedied partly by slipping a piece of mica between the plate and the tile. Their fuse boards, always of marble, as they found slate too unreliable, were carefully insulated on porcelain or ebonite insulators from the iron frame or wooden bearers. If the marble touched the iron at any part down went the insulation. The ideal system would be, of course, to connect all fittings, electroliers, standards, &c., direct to the iron pipes, but at the present time it was found impossible to get sufficient insulation between the frame and the lamp holders to allow of this being done, and it was necessary to carefully insulate the fittings from the pipes. One point in conclusion seemed to be of importance—the question of gas mains touching the iron pipes. He urged that the iron pipes should be continuously connected throughout, and an efficient connection from the pipes made to earth at one or two points; then it would not matter whether the pipes touched gas or water pipes, or, as was certain to happen, the iron joists of the building. Unless these precautions were taken it was conceivable that serious consequences might follow.

*Mr. R. E. B. CROMPTON said the remarks he wished to offer lost a great deal of point through being given at the wrong end of the discussion. He had intended in December to open the discussion by pointing out to the members that a committee had been sitting for some months to revise their wiring rules, and that that committee looked with great interest to the discussion to follow these Papers, as the question of casing and of various systems of conduit and concentric wire has been under consideration, and they hoped to hear the experience of members in regard to the use of these various methods. To a certain extent they had been disappointed in this, and he regretted very much that so few remarks had been made by those who had used these systems and who, they had hoped, would have given them their experience. It appeared to him that they were on the eve of a very great revolution in the art of house-wiring. The new Board of Trade regulations in allowing the use of a greater pressure were also stipulating that one side of the system should be earthed, and therefore they had to contemplate a new condition of affairs, and they had really now to consider whether they could not at once direct their ideas to the most perfect system of wiring, which he thought had been already mentioned by one speaker, by putting one highly-insulated wire concentrically within a pipe which at the same time formed the casing and also formed the return wire. That did appear a very perfect system. No doubt it had many disadvantages for those accustomed to the present systems, but he believed that when thoroughly thought out they would really get to that in the end. They had to thank Mr. Andrews and Mr. Mavor for being practically the first to lead them in that direction. He believed he was one of the first speakers who had done justice to those gentlemen. His firm had used a considerable amount of concentric wiring, and it had been very successful. He was quite surprised to hear so little said in praise of the system by other speakers. No doubt it had been more used in factories and places of that kind than in private houses, but it had been used in very difficult situations, in places where it would have been difficult to obtain high insulation by the ordinary methods, and it had obtained that insulation by what he might call the air-tightness of the system, every single part being closed and the insulation resistance kept up by preventing the entrance of damp to all those very weak points to which previous speakers had called attention, the points at which the fittings were attached. This concentric wiring system was the only one which thoroughly drew attention to the importance of protecting and making continuous the casing up to these points where the air could be excluded from the insulation. It appeared to him so easy to do with the concentric system and so difficult with the double-wiring system that it pointed very much in favour of the concentric system. There was another point which had not been sufficiently dealt with, and that was the lamp fittings. Mr. Mavor had said how much superior the concentric lamps were to the ordinary kind. He thought they would find the double-wire lamp fittings which they had been using for some time past a great nuisance and very expensive, and householders would find that they made their insulations very costly to maintain. The reason was obvious; they had to get a number of small parts, and it was difficult to make comely fittings with so many small parts. This was greatly avoided by the concentric lamp fittings, and was a point strongly in their favour. He thought they might find other strong points in the extra simplicity of only having one insulated wire. He wished very strongly to say, speaking as one of the committee on wiring rules, that one of the real good things they had got out of this discussion was the strong condemnation of casing, and it was evident that the days of casing were numbered. Casing had been a very good servant when nothing else was available, but the time has come when they must go in for something more substantial and less liable to cause a

Digitized by Google

trap in the shape of electrolytic bridges between the wires. There could be no doubt that it had caused these traps and that fires had resulted, although probably Mr. Heaphy would not admit it.

Mr. BATHURST, in his reply, said that an analysis of the criticisms advanced would show that the economical rather than the technical side of the question had been taken throughout. Starting with his five cardinal points for good wiring—safety, durability, convenience, accessibility, and economy—although convenience had, in some small measure, been touched upon, the last two points were the only ones that really stood questioned. Taking accessibility first, perhaps the main criticisms were at once removed when he stated that he used this word mainly in the sense of reliability. Conductors were not to be pulled in and out, except in the case of mishap; but he maintained that it was a factor of paramount importance to feel that it was possible to remove or replace electric conductors without any disturbance of their surroundings. It was Mr. Corlett, he thought, who said he was of opinion that there was a great deal of unnecessary prejudice shown about burying wood-casing enclosing wires directly in plaster, and argued that they had never yet heard of householders complaining of the "inaccessibility" of their gas pipes. Perhaps not: but a gas pipe, under ordinary circumstances, would not allow more than a certain quantity of gas to pass through it, no matter how many burners were put on to it; the flow of gas could never damage the pipe. If gas pipes had an unfortunate facility for leaking or bursting upon the slightest provocation, say upon the appearance of moisture or an unanticipated extra consumption, would they not have complaints? Would not every gas pipe have to be accessible? Several speakers have intimated the necessity of controlling the work of irresponsible workmen or contractors; have any suggested a "check" which is more legitimate or satisfactory than "accessibility"? Turning to economy, this was really the crux of the whole question. It appeared at least to be tacitly admitted that wood-casing was technically wrong and undesirable, although its cheapness and ready convenience were in some quarters considered to outweigh its immediate or prospective disadvantages. As he had tried to point out the technical defects incident to its use and employment, those conservatives who still pinned their faith to it had questioned conduit methods on the score of economy. He would try and rebut their statements. Those critics all admitted the mischievous and harmful commercial conditions which now obtained in the electric wiring industry, and in face of the complaints rife from every section of it they could indeed hardly do otherwise. He believed they had reached the turning point when inquiry into their present methods must and would be made, for, in spite of an enlarging commercial field it could almost be said that no one was deriving any benefit. The wireman complained that he could not make a "living wage," and was being ousted by inferior workmen. Wood-casing manufacturers said that they made casing without profit, and simply in order to keep their moulding machines full of work. The porcelain manufacturers were combining in an endeavour to keep up even present prices, whilst the sum total effect was being most seriously felt by the electrical supply houses, who were asked to make cheaper fittings and extend longer credit. Those conditions must be faced and a solution found. He contended that the principle they had heretofore been working upon was incorrect. They had been using wood-casing and metal pipes, and by so doing had not only introduced unnecessary difficulties and troubles, but had crippled themselves commercially. For want of any suitable protecting medium they had had to adhere to highly insulated, costly and expensive wire, but as a principle they had insisted upon having electric conductors insulated so that they could practically look after themselves without receiving anything beyond a slight mechanical protection from the supporting or surrounding medium. They had now nearly exhausted that demand for wiring which came from those who were willing to pay any price they were asked, and were beginning to feel the pinch and necessity for lower cost wiring. He held that wood casing or ordinary metallic piping was unable to meet those conditions. Let them take the cost per point to a contractor for wiring a certain building, as say 10s. per point (that was for the wiring only, without fittings), the analysis of this cost would probably be approximately, 1s. 6d. for wood casing and accessories, 4s. 6d. for wire and jointing material, 4s. for labour of erection. Casing was the lowest item, whilst labour and wire came out about equal. His contention was that it was advantageous to the contractor to employ methods which would reduce the labour item, and perhaps also the wire item, even if the other one remaining—casing or other supporting material—was thereby increased. If using the plain insulating conduit then before them, the work would cost, say, 3s. for insulating tubing and accessories, 3s. for wire, and from 2s. to 3s. for labour of erection. The special twin wire to be used was listed at prices 25 per cent. lower than the ordinary 400-megohm quality, and contractors could testify to the satisfaction it gave, and the labour-saving possibility of conduit methods. He was speaking from what had already been done, and stood by the statement that contractors could buy plain tubing and special twin-conductor wire together at the same cost as ordinary wire, so that the cost of wood casing was entirely saved. Technically considered, wiring of that nature must, on fair examination, admittedly be at all points superior to that employing wood casing; practically it has distinctly proved itself so in other countries, and it was making its reputation in England. Answering Mr. Rawlings' point as to "flexibility," he did not think that this was really necessary, and did not know how to make a flexible conduit "nail-proof" without making it "as hard as iron." Several speakers had advocated that iron piping was preferable to wood casing, from the fact that it afforded better mechanical protection. He was glad to hear one engineer at least—Mr. Campbell Swinton—say his experience made him believe that iron piping led to as much and even more trouble electrically than wood casing. Many well-known contractors had personally told him (the speaker) of the troubles they had already experienced with iron pipe—some of those faults were caused electrolytically, others of the damage done to the rubber insulation by excess of oil used when screwing up the couplings of pipe length; others of mechanical injury to wires whilst being drawn in, but strange to say, they had in that room, before their brother contractors, preferred to remain silent. Surely it was better to face the question there and find solution rather than wait until the public themselves decided whether or no there was any cause to find fault with it. Economically, however, they had no ground to stand upon; they could not, if following their present lines, give a system of iron piping with two or even one insulated copper wire inside it, and compete in price with ordinary gas piping. Although it might appear paradoxical, that could be achieved with an insulating-tube system, even if that tube had to be iron-armoured throughout its length. One or two speakers had doubted the necessity of placing an interior insulation on the inside of an iron pipe. They could take it that if it was doing no actual good there, it was at least doing no harm. The main fault in their eyes was that it added extra cost. It would be allowed that a lining prevented mechanical damage to the wire and increased the facility with which wires could be drawn in. It prevented internal condensation, and so obviated the presence of moisture and consequent rust. It must, therefore, tend to preserve the conductors under more favourable conditions. The insulating coating being under the iron pipe was not liable to any chance mechanical injury, and therefore, some sort and thickness of insulation could always be depended upon. In other words, insulation was added to the conductors. Did not this fact of being able to preserve some insulating material intact under all circumstances tell against those who advocated a very high insulation on the wire itself? His statement as to the actual insulation that particular lining gave to conductors within it, and the voltage it could stand without breaking down, as well as its shielding and subduing effect in the case of a short circuit, he could only accentuate by asking those interested to verify by test. Two million lamps were making that test in other countries. So much for technical reasons for advocating insulated iron pipes. If economy was sought, the co-operation of the wire manufacturer must be invited. Without arguing the fact that the present quality wire had primarily been designed to look after itself, and that instances had been given by which its possibilities in that respect could be proved, and admitting that the present type of insulated wire was as near the margin of efficiency as it should be, consistently for present methods, it could be urged that other types could and should be found. Had those who cried out against permitting lower insulation wires ever considered their own practice? Had those critics ever protested against the use of the ordinary flexible cord? The insulation test on that (excepting the vulcanised variety) could not be taken in water, and probably gave 300 megohms in open-air conditions. The insulating medium was a thin strip of pure rubber secured by a cotton covering. Oftentimes the rubber was a covering only in name. Yet experience surely sanctioned its use and admitted its convenience and economy. Did those critics remonstrate because they found commercial exigencies made it convenient to put further trial on that thin insulation by hanging a 3lb. or 4lb. weight at the end of each cord in the shape of lamp holder and shade? What did they say to its further aggravation by passing it over a number of friction pullies in adjustable fittings? The present stress of competition was noticeably increasing the amount of flexible cord being used, and his critics must notice that single lamps were rapidly changing into three or four light clusters. The development of that practice might not prove that it was right or even desirable, but he maintained that it did point to the possibility of getting away from the "megohm" variety of wire. What harm, he asked, could result even if wires of no better insulation, were installed, in an armoured insulating tube which could look after them mechanically and electrically, and in which any short circuit it was possible to make under practical conditions was rendered innocuous. Once this question of wire was settled, they saw the gain of further advantages from conduit methods. A small twin conductor was employed which required a tube of smaller orifice for the conveyance of electricity than was required for the conveyance of gas, taking light for light capacity. An armoured insulating tube created the possibility of a large labour saving factor, for sliding couplings and cemented joints could be used and would make a water tight electric system. Screwed couplings were rendered necessary in gas piping so as to successfully resist the internal pressure. Working on centre of distribution methods they would find that only ⅜in. and ½in. tubes need be used, for all twin conductors up to 5 or 6 ampere capacity would go into the former, and up to 10-12 ampere capacity in the latter. Sub-mains could feed from main fuse and distributing boards in ¾in. or perhaps 1in. tubes. The bugbear of wood-casing, the difficulty of estimating labour, would be removed, because the conduit wiremen would put up tubes by contract per foot run as was now being done with gas piping. Tenders for work would then become comparable with one another. He would like to support Mr. Geipel in his statement, or in his belief, that the Edison lamp holder was the best yet produced, both for socket and lamp; the vibration difficulty had been entirely overcome, and the holder satisfied every requirement. His belief was that they were already in a position to compete directly with the cost of gas piping. Insulating conduits had prejudice to overcome just as the other innovations of modern days. It might be of interest for them to learn that in spite of difficulty and opposition the last nine months had not been wasted in respect to the particular system he advocated, for, thanks to the co-operation of the General Electric Company, they could estimate that some 25,000 incandescent lamps in England were already testing the merit of conduit methods. So far he had only dealt with the criticisms made on his own Paper; but if it would not try their patience too much he would like to refer to points of resemblance and dissimilarity between Mr. Mavor's Paper and his own. He must challenge Mr. Mavor to show the superiority of the concentric system at any point, mechanically, electrically, or commercially. Again, whilst he appreciated the ingenuity with which Mr. Mavor had worked out his metal joints, he considered that it was open to criticism at least from its electrical functions. Poor joints heated and caused trouble

Digitized by Google

They had taught their wireman that he should never depend entirely upon solder for a jointing connection even if he must occasionally use it as a fuse. He had been told to make a mechanical connection and rely upon solder to make it airtight. It seemed to him that Mr. Mavor required his solder to fill a current-carrying function. At any rate the simplest method of jointing would be preferred, and, given his choice of two evils, he would rather chance an ordinary mechanical connection under a screw head. The main objection he made to the concentric system Mr. Mavor so admirably and forcibly advocated—and sooner or later those points would have to be fully discussed—were lack of accessibility and the grounding of the outer. Accessibility he had already accentuated, but he thought conviction grew upon one the more the point was discussed. Mr. Mavor twitted accessibility as a "relic of olden days." It might be so, but there are many engineers who would cherish it for some time to come. As regards grounding the outer, that one question could be discussed with an evening to itself. Even admitting the desirability of earthing the outer in street mains, personally he did not see the wisdom of enlarging the distributing network *ad infinitum* by including customer's premises. That end he would rather suppose should exist only with both wires insulated. The consumers' wires had to be installed under every kind of trial, contiguous with gas and water systems and passed over steel girders and other metallic constructions. Would Mr. Mavor have all those earthed as well, as if not he feared hazardous conditions would arise. The risk of electrolysis might be greatly over-estimated, but the troubles referred to in America had, he was creditably informed, convinced the authorities that even one-thousandth of a volt difference of potential was too much, and meant deterioration, if not destruction to gas and water pipes and other metallic bodies in the vicinity. After listening to Mr. Mavor's eloquent exposition of the advantages of a grounded outer, he was surprised when on his last page he suggested two simple remedies which *might* be adopted. He should like to have heard some discussion on that point, particularly when they had heard Mr. Andrews express his pet ideas, and they found the two champions at variance. Mr. Mavor seemed to imply the necessity of keeping intact (by a protecting lead sheath) a light insulation over the whole length of the outer conductor, except at distant ends. That being so, he asked him why not keep a slightly heavier one, and, following Mr. Andrews' leadership, use an iron armour instead of a copper tube, and having got so far he should by preference put two insulated conductors inside it. When Mr. Crompton could show them how to use one insulated wire in an ordinary iron pipe, he would try and prove commercially the advantage of putting a *bare* conductor in an armoured insulated pipe.

LONGITUDINAL LIGHT.*

BY G. JAUMANN.

The following theoretical dissertation consists of two portions: in Chapters 1, 2 and 5 results are communicated concerning the nature of light in a vacuum and of cathode rays, which follow from the experiments of Elster and Geitel, Lenard, and the author taken together; in Chapters 3 and 4 a theory of electric phenomena in rarefied air is propounded, which makes cathode rays and kindred phenomena perfectly intelligible.

I.—Determination of the Direction of Vibration of Electric Rays.

Introduction.—In a previous Paper † (1888) the following law of discharge was propounded: "Oscillations of electric force taking place immediately at an electrode and in a direction normal to it (*see* pp. 793 and 802) have a specific favourable effect upon the discharge, but, in order to have an appreciable effect, their amplitude must be the greater, the greater their vibration period."‡

In the present state of our experimental resources this discharging effect may be produced not only by light, but by electric rays falling upon the electrode, and by electric wire waves conducted towards the electrode. In all these cases the effect shows a distinct difference of species.§

The oscillations of electric force have a greater effect as the static electric field in the immediate neighbourhood of the electrode increases in strength. The product of these two factors determines approximately the occurrence and current strength of the discharge.

* *Wied. Ann.*, 57, 1, pp. 147—184, 1896.

† Jaumann, *Wiener. Ber.*, 97, p. 765.

‡ Of this specific effect of electric oscillations the Hertzian effect of ultra-violet light (1887) is a special case. The fact that the period of the oscillations with which I worked was 10^6 times as great, and the amplitude had also therefore to be 10^6 times that of the ultra-violet light, made it very much more difficult to discover that these slow oscillations also have a specific discharging effect. But decisive experiments were quoted (*see* pp. 785, 788, &c.) to show that these great and slow oscillations do not only act by increasing the electric intensity of the field. To a first approximation the product of the amplitude into the frequency (or, in other words, the maximum rate of change of the electric force during the oscillation) is a measure of the discharging effect.

§ My experiments may also be regarded as an imitation of the Hertzian light experiment by means of wire waves, but they were undertaken as original research. At that time (1888) the imitation of light experiments with slow electric oscillations was not yet undertaken, since electric rays were still undiscovered. Also the absence of effect from ordinary light would have militated against the supposition that electric waves of still greater period should again be effective, which, nevertheless, is the case.

Method.—The above law of discharge offers a means of investigating electric rays. This method has been found effective, as will be shown in the cases governed by Maxwell's theory, and is now to be applied to further phenomena.

The law of discharges was propounded without reference to the range of phenomena to which it is now to be applied. Experiments with electric rays, or photo-electric experiments, have hitherto not contributed anything new to it. Neither have theoretical suppositions in this direction influenced the formulation of this law. It is easily recognised, by the whole manner of expression and the date of the Paper referred to, that it belongs to the pre-Hertzian period.

Limitation of the Method.—Since it is almost exclusively the electric oscillations taking place in the immediate neighbourhood of the electrode surface which influence the discharge, a free ray can hardly be tested by the aid of discharge experiments, but only a ray reflected by a conductor, good or medium, or by an electrolyte—and even then only at its point of reflection. But beside the Hertzian rays there are also luminous rays and rays of a different nature (cathode rays) which are open to our method.

Further, the ray is not tested under normal conditions, but in the presence of the discharge, or, at all events, of the great static force of the field. The ray does not simply superimpose itself upon the discharge field, but produces the discharge, and therefore may also itself suffer a modification.

Testing the Method by Hertzian Rays.—According to the discharge law, only that component influences the discharge which coincides with the normal upon the electrode. A vibration parallel to the surface has no influence whatever.*

This gives a means of experimentally determining the direction of electric oscillation of a ray.

Faraday, Hertz,† Naccari‡ and others describe experiments which I should describe as the production of a discharge by the Hertzian rays proceeding from an adjacent discharger. They describe this effect as undirected, however. But according to the discharge law the ray must show a maximum effect when its electric oscillations are perpendicular to the electrode surface, and none when they are parallel to it.

Mr. J. Wanka§ made this experiment (different orientation of the exciter) with the complete effect predicted, and that not with a convection discharge, where it is quite easy, but with a spark discharge, which requires great delicacy.

We see, therefore, that the direction of the electric oscillation of a ray may be determined by discharge experiments.

Proof of the Electric Nature of Light.—By reference to the discharge law, *i.e.*, the experimentally studied effect of electric oscillations, the Hertzian light experiment may be regarded as a qualitative proof of the electric nature of light, supposing that the vibrations of no vector besides that of the electric force have any effect. There is no reason to suppose otherwise.

Now, according to Hertz, light favours discharge. Hence one of the vibrating light vectors is electric force.‖

Confirmation of the Discharge Law in Photo-electric Phenomena.—Theory gives us information concerning the direction of vibration of a polarised ray of light. On the strength of my discharge law it was predicted in 1892¶ that a polarised light ray can only have a discharging effect when its electric oscillations have a component in the plane of incidence. The experiment referring to this, which Hertz (1888)** and Wanka (1892, *loc. cit.*) had unsuccessfully tried to perform, the former without special theoretical views, did not succeed in my case either, owing to the difficulty of obtaining strong parallel polarised ultra-violet light.

This difficulty was surmounted in a beautiful manner by Elster and Geitel,†† who had found that alkali metal electrodes are sensitive to ordinary light, and who employed a mirror of potassium-sodium alloy as an electrode. Their experiment (1894) had almost perfectly the effect predicted (1892). A ray falling under the angle of

* Elster and Geitel have not yet accepted this proposition, in spite of their measurements with polarised light. They say (*Berl. Akad.*, p. 213, 1895; *Wied. Ann.*, 55, p. 692, 1895): "A ray of light oscillating in the plane of incidence excites a stronger photo electric current than a ray of equal brightness vibrating parallel to the cathode surface in the proportion A : B." The ratio B : A may increase up to 1 : 3.

† Hertz, *Ges. Werke*, 2, p. 288.

‡ *Wied. Beibl.*, 13, p. 421, 1889.

§ Wanka, "Mitth. d. Deutschen Math. Gesellsch. in Prag., 1892." It is easily seen that this work was executed under a course of ideas suggested by myself.

‖ The explanation of the Hertzian light effect as a special case of my discharge law was published in 1892. The previous explanations by Wiedemann (1888) and Elster and Geitel (1891) only assume intermediate electric effects. They proceed from the assumption of a *resonance* of the molecules of the cathode, and no conclusion was arrived at with regard to polarised light. The molecules can hardly resound both to ultra-violet light and to vibrations 10^6 times slower.

Digitized by Google

70deg. has almost no discharging effect when its electric oscillations are normal to the plane of incidence.

By a precise prediction of this kind my discharge law receives a great claim to confidence. In the following it shall be utilised—

(1) For determining the direction of vibration of cathode rays, with reference to previous experiments by Lenard and myself (Chap. 2);

(2) For determining the direction of vibration of light in rarefied air, with reference to the measurements of Elster and Geitel (Chap. 5).

Simple Validity of the Discharge Law.—The whole range of discharge phenomena is open to explanation in various essential points. A complete insight into the nature of the discharge is certainly not afforded by the discharge law alone. It is all the more remarkable that this law may be so simply and smoothly applied to the remote optical experiments. This facility, this elimination of doubts, without further ado, is a sign that the present investigation has a good direction.

The excitation of discharge by variations of force is the simplest of all discharge phenomena, the first generalisation from them, and the point of departure for theory.

II.—Nature of Cathode Rays.

Occurrence of Interference Surfaces in the Blue Cathode Light.—Under this title I published in 1892 a Paper which is connected with what follows; I therefore take the liberty of quoting its most essential parts, especially as it is rather inaccessible.

(From the "Mittheilungen der Deutschen Mathematischen Gesellschaft in Prague, 1892"—abstracted in *Wied. Beibl.*, 17 :—)

"The cathode rays, according to Hertz, take no part in the discharge; they are more like rays of light emitted by the cathode, but light rays with special properties. E. Wiedemann considers them to be ordinary ultra-violet light. This would, indeed, explain their high absorption, but not the peculiar deflection phenomena, and it would be unintelligible how the cathode could emit parallel-rayed ultra-violet light. It is much more obvious to suppose that the cathode rays are longitudinal electric waves, or we might say *longitudinal light*. Such waves must indeed be emitted by the electrodes under the violent alternations of potential which they undergo. The high absorption of these rays may be a peculiar property of theirs, and for this reason natural light might not have any longitudinal components. Perhaps Hertz also inclines towards this assumption, since he compares the magnetic deflection of the cathode rays with the magnetic rotation of the plane of polarisation of light.* About this, interference experiments must inform us. In the following, a few experiments on this matter are described, which, however, do not imitate interference experiments of optics, but adapt themselves provisionally to the peculiar nature of cathode rays. A periodicity of cathode rays could not be proved, but the great influence exerted upon their interference by their coherence and their equal phase could. Possibly the wave length of these rays is very great.

"When I first made a minute observation of the discharge in a so-called electric egg—*i.e.*, between spherical electrodes in rarefied air—I observed, in the re-entrant angle in which the negative ball joins the stem, a conical surface shining much more brightly than the blue stratum, which surrounded the stem like a collar and bisected the re-entrant angle. This is produced by the interference of the blue stratum proceeding from the ball and from the stem. But it is curious that this interference and the greater luminosity thereby produced is limited to a well-defined surface of mean position. If a flat negative electrode is placed opposite a cylindrical one of parallel axis, a sharp parabolic interference surface is obtained. The interference surface between two flat surfaces inclined to each other is plane and bisects their angle. With more complicated cathodes these interference surfaces are found at all constricted places in the blue cathode light. Owing to their greater luminosity these surfaces appear to protrude beyond the blue strata. The position of the positive electrode in these experiments is almost irrelevant. These interference surfaces are strongly distorted by magnetic forces, and that just like cathode rays proceeding along them from the cathode. The cathode rays, proceeding normally from the two cathode surfaces, are therefore deflected together, and proceed along the interference surface.

"For the closer study of the phenomenon two elongated parallel plates 1cm. apart were used as a cathode, the positive plate being fixed equidistant from their ends and normal to the negative plates. The two negative plates cover themselves both within and without with the blue cathode light, but the inner layers are much narrower, brighter, and nearer to the electrodes. This may be due to the deflection of the cathode rays by the second cathode plate, which may be greater at higher pressures, just like the magnetic deflection. When the pressure is diminished these blue strata approach each other and finally coalesce, forming a well-defined plane limiting surface, which finally remains alone and accurately bisects the space between the two plates. The cathode rays run parallel to the cathodes in this interference plane, but emerge from between them in all directions.

"From the negative pole of an influence machine provided with a spark gap, two wire connections are brought to the cathode plates. In this case the interference plane is quite sharply defined even when the wires are many metres long, but only when the wires are perfectly equal in every respect. With quite small differences of length, say 10cm., the plane is considerably broadened out. With still greater differences the whole space between the plates is filled with light, which finally collects about the plate connected with the shorter wire. Hence the electric rays produced by the spark gap and approaching through the wires must arrive at the cathodes with exactly equal phases in order that the cathode rays may form the interference surface. If the two cathode plates are joined by a long loop of wire and the negative conductor of the machine is joined by a sliding contact, the great sensibility of the interference surface for any displacement of the contact from the middle of the loop is very evident. If we may judge from this sensibility concerning the wave lengths in the wires which produce the cathode rays, we must regard them as varying from 0·5m. to 1m. I have sought other points along the wire loop distant by whole wave lengths, and therefore equally as suitable as the centre, but have not succeeded in finding such points, evidently because it is waves of very different wave length which produce the cathode rays." The *broadened* interference surface observed after a slight displacement of the contact from the centre corresponds, we may say, to a spectrum of interference surfaces belonging to cathode rays of different frequencies.

Cathode Rays in the Axis of Symmetry.—I shall first mention the obvious reasons for regarding the cathode rays as longitudinal electric waves.

First and foremost we have the strong occurrence of the cathode rays in the axis of symmetry of discharge space. Their intensity is greatest there and decreases outwards. These are, therefore, longitudinal or scalar, if only from considerations of symmetry (at least along the axis, *i.e.*, essentially). The latter alternative is excluded, since they were recognised long ago as *electric* waves (E. Wiedemann, Hertz).* A radial or tangential transversality may, of course, occur at their bounding surface without being essential.

I can only understand E. Wiedemann definitely, and Helmholtz (in the letter referred to) questioningly, attributing transversality to the cathode rays if we imagine them to be phenomena of irregular and varying transversality like natural light, but do not consider this either as sufficient or advisable.

Necessary Presence of Longitudinal Electric Waves.—It is quite a special property of the Maxwell-Hertz equations that they do not admit of longitudinal waves. Almost any modification of them makes longitudinal waves appear as possible.

Now it is especially rarefied air which is so peculiar with regard to electric phenomena that it is impossible to regard Maxwell's equations as sufficient. The mere fact of discharge already contradicts them.

But with the invalidity of these equations there is room afforded for longitudinal waves, and these will actually occur when the necessary limiting conditions are given.

This necessary condition is given by the variations of electric force at the electrode surface, produced by the waves approaching along the wires. In fact, the cathode rays become much more vivid when a small spark gap is introduced, thereby increasing the intensity of the wire waves.

Frequency of the Cathode Rays.—The experiments referred to concerning the behaviour of interference surfaces when the sliding contact is displaced give a clear indication of the order of magnitude of the period of the cathode rays. The exciting wire waves have lengths of the order of magnitude of 1m., and therefore a period of 10^{-8} to 10^{-9} seconds. This is probably also the period of the cathode rays. This experimental deduction places me in the strongest antagonism to the assumptions of all other workers.

* As will be seen, I was the first, and I believe the only one who had reasons (1892) to explain the cathode rays as longitudinal electric rays. I am pleased to think that at that time I already stated that I conceived the idea on reading Hertz's work (*Wied. Ann.*, 19, p. 782, 1883). Hertz has never published anything concerning his opinion of cathode rays. Still, it has been recently proved that he considered them to be longitudinal electric waves (of Helmholtz's theory?). This follows from a letter by Helmholtz to Hertz, written in 1883 and published in the *Ges. Werke*, and from a passage in the manuscript of a lecture delivered by Hertz at Kiel in 1884, and now in the possession of his widow.

* After Hertz's views those of E. Wiedemann most closely approach my own. He was, as far as I know, the first to compare cathode rays with light. Further, he also (1884) searched for longitudinal electric waves, and regarded the positive stratified discharge as a longitudinal electric wave (*see* G. Wiedemann, *Electricität*, 4, p. 593). Quite recently (*Zschr. f. Electrochem.*, 8, 1895) he definitely abandoned the transversality of the cathode rays, and declared them to be vortex motions in the ether. This may be a basis for future agreement.

Digitized by Google

E. Wiedemann regards them as ultra-violet light, and therefore attributes to them periods of 10^{-15} to 10^{-6} seconds. In that case the existing wire waves would have to have lengths equal to those of ultra-violet light, and this contradicts my experiment. Lenard goes so far as to attribute wave lengths of the order of magnitude of the molecules to them, as they are to be diffused by the molecules.

But with their ultra-violet nature the cathode rays also lose their transversality. For if they were transverse, without being ultra-violet, they would be ordinary light or Hertzian rays. But this they cannot be, since they have totally different properties.

The proof that cathode rays have the period of ordinary wire waves is therefore a further proof of their longitudinal character.

Experimental Proof of the Longitudinal Character of Cathode Rays.—This proof is founded upon the discharging effect of cathode rays, with the aid of the method developed in the first chapter.

About this Lenard* has made experiments which suffice for this proof, although they have not yet been sufficiently varied.

According to Lenard the cathode rays have a strong discharging effect. They are therefore electric waves of great amplitude. The cathode rays also have strong discharging effect when their direction is perpendicular to the electrode surface. *Hence the direction of their electric oscillation coincides with their direction of propagation.* They are rays with a great longitudinal component, and, therefore, from symmetry, essentially pure longitudinal electric rays.

(To be continued.)

PHYSICAL SOCIETY.

At an ordinary meeting of the Physical Society, held on February 28, 1896, Prof. John Perry, Vice-President, in the Chair, Sir D. Salomons showed some experiments with incandescent lamps. A large electro-magnet is excited by means of a continuous current, while an alternating current is passed through an incandescent lamp. On bringing the lamp near the magnet the filament is set in vibration, which, if the lamp is brought sufficiently near the magnet, are sufficiently intense to break the filament. The number and position of the nodes formed in the vibrating filament are found to be independent of the natural period of the filament, but depend on the frequency of the alternating current.

Prof. S. P. THOMPSON asked whether it was not found that the number of segments into which the filament is divided depended to some extent on the natural period of the filament.

Prof. AYRTON said that the magnetic leakage was very large with the arrangement adopted, and he would like to know whether this method was a more sensitive one for mapping out the field than those ordinarily employed. In an instrument designed by Prof. Perry and himself, an alternating current was passed through a wire stretched between the poles of a magnet, and the tension of the wire was altered till the vibrations set up were a maximum. The natural period of the wire, and hence the frequency of the alternating current, was then deduced from the tension, &c. In Prof. Ewing's magnetic curve tracer, on the other hand, the natural period of the stretched wire was made as different as possible from the period of the alternations which were to be observed, so that the natural vibrations of the wire did not influence the results. The author's arrangement appeared to him (Prof. Ayrton) to be intermediate between these two, and it would seem that the natural period of the filament would to a certain extent influence the results.

Prof. PERRY suggested that the lamp might be held in a very steady support, so that after the large vibrations due to the natural period of the filament had died out, the vibrations of the period of the alternations alone could be observed.

Sir D. SALOMONS, in his reply, said that the arrangement was not intended for making *measurements*. A lamp had been fixed in a steady clamp, and the current passed for many hours, but the character of the vibrations remained unaltered. He had found the vibrating filament useful for microscopic work where a surface rather than a line of light was required.

Prof. FLEMING read a Paper by himself and Mr. Petavel on

"An Analytical Study of the Alternating-Current Arc."

The first part of the Paper consists of an analytical study of the distribution of light throughout the various radiating regions in the arc when supplied with electric power of known constant amount, the periodic variations of the current through the arc and of the potential difference between the carbons being at the same time recorded. The power was measured by means of a bifilar wattmeter, while by means of a series of mirrors and a rotating disc carried by a sychronising alternate-current motor, the mean value of the light taken from any part of the arc was compared with the instantaneous value of the light taken from the same part of the arc, and taken at any assigned instant during the period. Thus the arc itself was its own standard, and difficulties due to slow variations in the mean light of the arc disappear. The facts observed may be summed up as follows:—The purple light of the true arc undergoes a periodic variation, and, as far as the eye can judge, is completely extinguished during a certain interval during the phase; it has equal maxima values during the period, at instants slightly lagging behind the instants of maximum power expenditure in the arc. On the other hand, the illuminative power of the carbon crater varies between a minimum value and two unequal maxima; the greater maximum occurring when the carbon is positive, and at an instant slightly lagging behind the instant of maximum power expenditure in the arc. The second part of the paper consists of a comparison of the efficiency of the alternate-current arc regarded as a light-giving agent as compared with that of a continuous-current arc taking the same mean power. Using two arcs, which may be regarded as typical of those used in practice, the mean spherical candle-power was compared for equal expenditure of power in the arcs, and it was found that for the alternating-current arc employed the total mean spherical candle-power was always less than that of the continuous-current arc. Lowering the frequency seems to decrease the efficiency of the alternating-current arc.

Prof. AYRTON said the behaviour of the alternate-current arc was of great interest, for the power supplied could not be measured by simply multiplying the current by the electromotive force, since the current lags behind the volts. The resistance, *i.e.*, the ratio of the current to the electromotive force, also lags; but the authors do not appear to have made any attempt to measure the true resistance. The authors were to be congratulated on the guarded tone they had adopted as to the bearing of these experiments on the question of the relative efficiency of the alternating and continuous-current arcs. In a previous communication, one of the authors had stated that the alternating-current arc must necessarily be a less efficient light-producing agent than the continuous-current arc. Although the last set of curves given in the Paper might appear to support this supposition, he (Prof. Ayrton) felt that the difference obtained was probably due to the fact that the alternating-current arc was not being worked under proper conditions. The quality of the carbons and the length of the arc have a most important influence on the efficiency of an arc. At present our knowledge is not sufficient to allow of our stating definitely whether or not an alternating-current arc can be made as efficient as a direct-current arc, but there is no doubt that it will be possible to get much better results than are at present obtainable.

Prof. S. P. THOMPSON said that when the fact of the existence of the difference in phase between the current and volts in an alternating arc was first published, he had made some experiments which showed that there was a lag and not a lead—*i.e.*, that the arc acted as if it possessed self-induction. The resistance also lagged, and he thought this lag might be due to a thermal lag. The temperature of the arc will lag behind the current both when it is increasing and when it is decreasing, and if the resistance of the arc depends on the temperature of the vapour in the arc then the resistance would also lag behind the current. It was not possible from *a priori* reasoning to say whether or no an alternating-current arc could ever be obtained of any efficiency equal to that of the direct-current arc. With suitable carbons, length of arc, current and volts it seemed to him that it might be possible to obtain an equal efficiency. The light-giving process in an arc is not merely an irreversible degradation of electric energy into heat, for the difference of potential between the carbons may be written $V = a + b l$ where a may be regarded as a back electromotive force and $b l$ as a true resistance. The first term of this expression does not vary with the length of the arc, l, but the second term does. Multiplying through by the current, C, the equation Watts expended $= C a + C b l$ is obtained. It is the first of the terms on the right-hand side which is a reversible effect, and corresponding to the power expended in driving the current against a back electromotive force, on which the light given out chiefly depends due to something occurring at the crater surface.

Mr. BLAKESLEY asked whether Prof. Thompson's idea of the light being due to the reversible part of the process was not a strong argument in favour of the direct-current arc?

Prof. AYRTON said that in two communications made to the Congress held at Chicago it was shown that even with direct-current arcs there was a certain length of arc for which the efficiency was a maximum. Mrs. Ayrton had quite recently found that the efficiency of arc lamp carbons altered with time. Prof. Thompson's suggestion as to a thermal lag was a valuable one.

Prof. FLEMING, in his reply, said that when comparing two agents where there were so many variables, it was practically necessary to restrict the investigation. In their case they had kept the mean power constant and had left the other variables to take care of themselves.

The Society then adjourned till March 13th.

Electricity on Board Ship.—It is stated, says the *Engineer*, that the Russian naval authorities have decided to substitute in the battleships "Sissoi Veliky" and "Navarin," as well as in the cruiser "Rossia," a telephone invented by Lieutenant Kolbasyeff for the speaking tubes now used. According to the *Novosti* these vessels are also to be fitted with the electric alarm bells invented by Captain Vassilyeff for showing the ship has been hulled by shot.

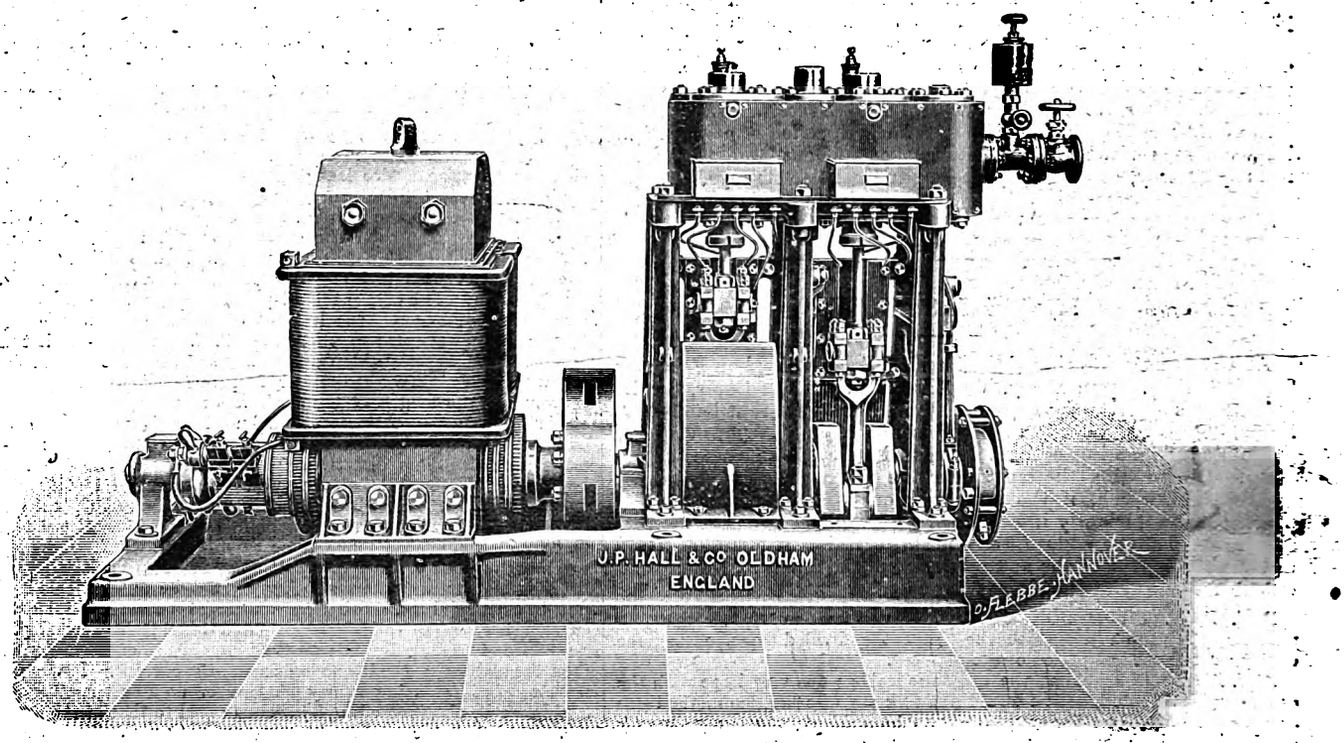
COMBINED COMPOUND ENGINE AND DYNAMO.

The accompanying illustration shows one of Messrs. J. P. Hall and Co.'s combined compound engines and dynamos specially constructed for ship lighting purposes. Three sets of these have just been completed to the order of Messrs. J. and G. Thomson (Limited), of Clydebank, for ss. "Kiev," the latest addition to the Russian Volunteer Fleet. We may also mention that this vessel has been fitted throughout with a complete system of electrically-driven fans, all the motors for which have also been made by Messrs. J. P. Hall and Co. The following description of the engines and dynamos will be of interest.

The cylinders are 5in. and 8½in., diameter by 7in. stroke, with the low-pressure valve between, and the engines are constructed to give 25 I.H.P. at 300 revolutions per minute, with 120lb. steam pressure when exhausting into the atmosphere. The moving parts are all as light as is consistent with strength, and the pistons, which are dome-shaped, are of steel, the cross-heads being of cast steel lined with magnolia metal. The connecting rods are of best forged steel of the ordinary marine type, with phosphor bronze bearings. The crank-shafts were also of forged steel, and each line of moving parts is separately balanced with weights forged on the crank-shafts, the cranks being placed on opposite centres, so that the engines are balanced as a whole and run with no variation without being in any way fastened down. The beds are made, as will be seen, with an extension for carrying the dynamos, the main bearings being cast on and truly bored in position and bushed with phosphor bronze bushes, the one at the flywheel end being double length to carry the weight of the armature and flywheel. The governors are of the firm's patent automatic type, which are so arranged that they vary the stroke of the eccentric from 2in. to 1in., and which from their design have very little friction and are very quick to take up any small variation in load, and the engines govern to within 2 per cent. with no load or full load.

The dynamos are slow speed, with drum bar armatures, and give 120 amperes at 100 volts, with a maximum temperature rise of 60°F. after six hours' run with full load, and the magnet coils are wound on strong sheet iron bobbins, with teak flanges carrying the terminals. The lubrication throughout is continuous, and ample provision is made for catching the waste oil, whilst the cylinders are provided with spring relief valves as well as ordinary drains.



The whole arrangement is exceedingly compact, and takes up comparatively only a very moderate space, so that it is specially applicable for lighting purposes on board ship where the above point is a matter of importance, and the firm are supplying a large number of these engines and dynamos to the leading ship-building establishments and electrical contractors. The firm also make other types of engines, dynamos and motors, both for direct and independent driving.

PARLIAMENTARY INTELLIGENCE.

LIGHT RAILWAYS BILL.

On the order for the second reading of the Light Railways Bill, in the House of Commons, on Monday evening last,

Mr. LOUGH moved, as an amendment, "That this House declines to sanction any scheme for the construction of light railways which will increase the burden of local rates or add to the weight of Imperial taxation." He said that under the Bill every facility was given to the locality to enter upon the construction of unproductive light railways, and there was no clause which protected the local rates from the charge that might be placed upon them by local authorities who were carried away with the prospects of these railways. The object of his amendment was to afford that protection. He contended that the assistance given by the Treasury under the Bill was given in a most pernicious form. Instead of proceeding in the way laid down in the Bill, which would result in imposing burdens on the localities, the Treasury ought to offer inducements to private speculators to construct lines where they were likely to prove an economical success. The first light railway enterprise in Ireland was under the Liberal Bill of 1883. Light railways were built under an extravagant guarantee of 5 per cent. to be given by the locality, and if the Treasury were satisfied that the railway would be kept at work it refunded the locality 2 per cent. Eighteen lines had been opened. They were 600 miles long, and, he believed, were the worst constructed railways in Europe. The service was irregular and unpunctual, and the rates high. The cost ranged from £2,600 to £6,000 a mile. The local ratepayers had to pay the interest on the whole of the capital, and this year there would be £90,000, or 6 per cent., interest to pay on £1,500,000 capital sunk in these lines. It was a wicked thing to plunge Ireland, at a time of agricultural distress into this mischievous speculation. Instead of plunging gaily into light railways for England they ought to repair the mischiefs which these railways had done in Ireland. A rate of 2s. in the pound was paid in Ireland for light railways which were positively dangerous to travel upon. As to leaving the matter to local authorities, local authorities in England were no more to be trusted than local authorities in Ireland. Under the Bill of 1889 to promote light railways in Ireland the cost of construction ranged from £4,000 to £9,000 a mile, and one line cost as much as £15,000 a mile. Let it not be thought that the £1,000,000 mentioned in the Bill would meet the expenditure. The House in reading this Bill a second time would open a little tap which it would never be able to close, and a hundred millions might ultimately have to be expended.

Mr. PERKS, in seconding the amendment, contended that the Bill in its present form would be of comparatively little use in securing the construction of cheap light railways in the rural districts, and unless substantially altered or amended in Committee the House ought not to pass it.

Digitized by Google

Mr. SOUTTAR thought that if the financial clauses were altered in some particulars the Bill would become a good working measure.

Mr. GOLD said that if hon. members came from constituencies such as his, they would be unanimous in favour of State aid for these railways. In Essex there were at least 20 populous places and one large town distant from seven to ten miles from any railway station, and there were more than 16,000 acres out of cultivation. He thanked the President of the Board of Trade most heartily for the measure.

Mr. V. DAVIES strongly supported the Bill, and expressed surprise that a representative of one of the districts of the metropolis should be found opposed to it. He should have thought every representative of a great town or city would by means of this measure have been glad to have held out to agriculture the right hand of friendship. He trusted that the President of the Board of Trade would reconsider the financial part of the Bill, as it would be impossible for many places to pay 3½ per cent. for the money advanced.

Sir H. MEYSEY-THOMPSON pointed out that, with the sole exception of the United States, in every other country the State had an interest in the railways and contributed towards them. He suggested that the Railway Commissioners, the Board of Trade, or a similar body might be empowered to grant loans for the construction of light railways at 2½ per cent. and regulate these loans according to the circumstances of the district. His own belief as a railway director for the last 20 years was that these light railways would largely be made by the existing railway companies. The conclusion of railway experts was that it would be fatal to light railways if they were not of the same gauge as trunk lines, allowance being made for very exceptional cases in hilly districts.

Mr. WHITTAKER denied that agriculturists had suffered more than manufacturers, for anyone might see mills and factories lying derelict, but their owners did not come begging to that House for relief. The value of agricultural land to-day was as great as it was 50 years ago. The assessment under schedules A and B was in 1844 £40,000,000, and it was the same in 1894. Light railways would not effect an improvement; the cause of the evil lay much deeper than that.

Mr. BRYCE said that with regard to the financial proposals of the Bill, of course, nothing could be more popular than for a Minister to suggest Government grants in aid of such undertakings; but the House ought to take care that no improper demand was made upon the national purse. He thought that local authorities under proper safeguards might be allowed to subsidise undertakings of this character. As to the question of a subsidy from the Treasury, he thought no case had been made out to show that private enterprise would not deal sufficiently with this matter. He thought that the enormous difference in the cost of construction would encourage the great railway companies to take advantage of the measure. He would not go so far as to say that there might not be a case in which a particular class of industry might be entitled to special consideration by the State, but he did hold that the drawback to plans of this kind was that they necessarily tended to excite jealously between town and country. Another objection to subsidy by the State was that people would not make railways without a subsidy if they thought they could get one, and those of the railway companies who had been intending to make branch lines would probably hold their hands when they thought there was a chance of getting a subsidy. The policy of making grants from the Treasury was open to the objection that it subjected that Department to pressure from members and others advocating the claims of their particular localities. In countries where that policy had been adopted this pressure had been a source of much annoyance, and had been known to lead to something approaching jobbery. He hoped, therefore, that the provision respecting free grants would be expunged from the Bill. He feared that the million which the Treasury was to be authorised to advance would not go very far, and that the expectations raised by the Bill would be greatly in excess of the benefits conferred. By establishing this precedent they might be preparing serious difficulties for themselves in future years.

Mr. RITCHIE said it had been stated that the effect of the Bill would be to discourage private enterprise. Well, the main trunk railway system of this country was almost complete, and yet we were face to face with the fact that large areas of country were without any communication whatsoever, to the enormous disadvantage of those who were engaged in agricultural pursuits. The first consideration of a railway company before making a branch railway would be whether it would pay. If it would not pay, the branch railway certainly would not be made. He hoped that local authorities and landowners in agricultural districts would have regard to other considerations, that they would think of something more than mere return of interest, and would keep in view what was likely to contribute to the well-being of the locality. He hoped that under inexpensive conditions some lines would return a moderate rate of interest; but they could not look forward for the present to such a rate of interest as would induce private enterprise to embark in them. In Belgium, where there were a large number of such railways, the average rate of interest was 3 per cent. He doubted whether they would get private enterprise in this country, either in the shape of existing companies or private contractors, to make railways at a possible return of 3 per cent. and a probable return of something much less. Some hon. members had urged that 3½ per cent. was too high a rate of interest, and had mentioned that Consols only paid 2½ per cent. But there was a vast difference between advancing money on Consols and on the security of a light railway. The Treasury lent this money at 3½ per cent. practically without security, because the railway could not be of great value if it did not pay; and the Treasury only stipulated for the same rate of interest as the local authority. If the time should arrive when the local authority considered that 3½ per cent. was an onerous rate of interest, the Treasury would be only too glad to have its loan repaid. He had not, as the hon. member for Islington suggested, held up the Bill as a panacea for agricultural depression, but he did think the measure would do something to improve the agricultural industry. There were now large areas in the country from which agriculturists could not get their produce to a market without a large expenditure of money, which made their return almost *nil*. There were hundreds of thousands of acres of land far away from a railway station which must derive enormous benefit from the operation of the Bill. The State, local authorities, and landowners would be benefited, and he did not think the Bill would have that effect upon the rates which the hon. gentleman imagined. He trusted local authorities would take into account what was for the benefit of the community over which they presided, and he believed that in the end they would reap their reward by a condition of things greatly improved upon that which now unhappily existed.

Mr. LOUGH asked to withdraw the amendment, but it was negatived without a division.

The SPEAKER then put the motion for the second reading.

A division was challenged, but the cries of "No" were not persisted in, and the second reading was ultimately agreed to without a division.

THE WORCESTER WATER-POWER STATION.

The following Report of the Borough Electrical Engineer (Mr. E. T. Ruthven-Murray) to the Worcester Electricity Committee is of general interest:—

GENTLEMEN,—In order that you may better realise the result of last year's working, I have analysed the return and accounts in such a manner that a comparison may be made between our own figures and those published by other electricity supply stations, and in making these comparisons the charges for interest and sinking fund have been excluded.

Taken as a whole, our total costs figure of 2·97d. per unit sold is decidedly satisfactory, although it is higher than I anticipated. Nevertheless, if the average price obtained, 3·163d., were not so extremely low, we should have made a substantial profit.

Undoubtedly the figure in the costs which looks out of proportion is that of 1·06d. per unit sold, for fuel; and in the reduction of this figure I see most hope of lowering the generation in the future.

There are several reasons why this figure is so large, and pre-eminent is the fact that the available water power did not come anywhere near its calculated value, with the result that from the end of May until the end of November it was necessary to run a portion of the day on steam only. About Midsummer there was so little water in the Teme that as much as 75 per cent. of a total week's running hours were done on steam power. As the engines at the works are all of 286 I.H.P., we had no choice but to run these at the very low load which was the maximum that could be obtained, and at a load factor so small that high efficiency and low consumption of steam, and, therefore, of fuel, was impossible. A condenser was thought unnecessary when the works were equipped, but this omission is now made good, and will, I have no doubt, effect an economy in the steam consumption of the engines of upwards of £0 per cent.

Before it became necessary to run by steam power in the daytime, we were using Staffordshire coal entirely, but in consequence of repeated complaints about smoke, you instructed me to burn Welsh smokeless coal when found necessary, which, being considerably more expensive is an important factor in the cost of fuel. The reason for so much coal being used was to keep running for the electric pumping plant at the waterworks. I estimate that no less than 400 tons of coal were used entirely to keep one motor running during the summer. As the price we received from the Water and Sewerage Committee was only 1d. per unit it will be seen that over the whole year our costs show a higher figure than this for coal alone, and instead of making anything out of the day load found by these motors, you have actually lost money by having them on circuit.

During the summer the contractors were engaged in replacing the coils of the alternator armatures with others of improved type, and to test them it was necessary to run the machines for many hours continuously. As no water power was available steam had to be used, and testing accounts for some 80 tons of coal.

It is authoritatively stated that the past summer was one of unusual drought, therefore we may not be so short of water during the coming season.

We have recently improved the figure for cost of engine-room stores, by alteration of the lubricating arrangements on the machinery at the works. Of the figure 0·267d. per unit, 0·156d. is engine-room stores. The figure of 0·111d. for carbons is not a true result of the year's working, as the carbons used during the few months of last year were altogether omitted, and have been added here. We are now purchasing carbons at about 22 per cent. less than we were during last year, and in the next report the figure of 0·267d. per unit will be materially reduced.

The next figure of 1·038d. per unit for wages at works is low for the character of the station, and cannot be reduced except in so far as it will be from the larger output we may expect this year. It is apparent that this will fall proportionally as the output rises; the same remark applies to the figure for repairs and maintenance, which I do not anticipate will much increase. The figure which includes legal expenses, management, and insurance, may be altered other than proportionally, although the figure for rates, taxes and rents should share in the reduction from increased output.

Turning from costs to revenue, the most striking item is that of the average price obtained, which, excluding revenue derived from meter rents, property rents, &c., only amount to an average of 2·73d. per unit, a figure without parallel in the annals of the electricity supply business. The figure, including revenue from other sources, 3·16d., is lower than any

Digitized by Google

recorded. The waterworks motors are again mainly responsible for these figures. They were supplied with 103,644 units, for which we receive the sum of £431. 17s. This number of units bears the relation of 41·9 per cent. to the total output of 246,912 units. For the remaining 51·1 per cent. (143,268 units) we received £2,386. 8s. 2d., or an average of 3·99d. per unit, a figure above the lowest on record of other stations.

Bearing in mind the unusual difficulties we have had to engage with and overcome during the past year, our results cannot but be considered satisfactory. The number of lamps we have taken on is very gratifying, amounting to an increase of over 200 per cent., and I have no doubt, from information received, that we shall have a large accession of small consumers, from whom we derive a much better revenue per lamp than from most of the larger ones during the year.

THE MUNICIPAL ELECTRICAL ASSOCIATION.

The formation of the above Association was brought by Mr. John H. Rider before the meeting of municipal electrical engineers held in Westminster in July last to discuss the new Board of Trade Rules, and was warmly approved. It was felt that there were numerous important matters affecting the interests of municipal electrical undertakings on which intimate discussion and probably united action would be desirable, the following, among several others, havin been suggested :—

Board of Trade Regulations.

Wiring rules and the powers of municipalities in relation to their enforcement.

The repayment of loans.

The appropriation of profits.

The rating of electricity works.

The relation of electrical undertakings to other public services, such as gas, water, drainage, &c.

Matters of interest and importance concerning mechanical, electrical, and commercial questions.

The meeting also decided to appoint a committee of five to prepare a draft constitution for the proposed Association, and the following gentlemen were elected by ballot for that purpose :—Mr. Sydney W. Baynes, Mr. A. B. Mountain, Mr. John H. Rider, Mr. C. H. Wordingham and Mr. Arthur Wright. This Committee held a meeting on the following day, and appointed Mr. W. L. Madgen hon. secretary *pro tem.*, feeling that his services would be of value during the period of organisation, as he had taken a keen interest in the subject—being, in fact, the originator of the movement. The Committee completed its work in good time, and a draft of the proposed prospectus and constitution was sent out with a notice convening a general meeting for November 18th, at the Westminster Palace Hotel, Victoria-street, S.W.

This meeting was held in due course, the following gentlemen being present :—Mr. Arnot (Glasgow), Mr. Appelbee (Cardiff), Mr. Barnard (Hull), Mr. Vesey-Brown (Sunderland), Mr. Cottam (Hampstead), Mr. Christie (Londonderry), Mr. Edgcome (Kingston-on-Thames), Mr. Ellis (Southport), Mr. Gay (Islington), Mr. Gibbings (Bradford), Mr. Giles (Blackburn), Mr. Hesketh (Blackpool), Mr. Hope-Johnstone (Bedford), Mr. Jeckell (South Shields), Mr. Mitchell (Dewsbury), Mr. Mountain (Huddersfield), Mr. Ruthven-Murray (Worcester), Mr. Price (Portsmouth), Mr. Faraday Proctor (Bristol), Mr. Rider (Bolton), Mr. Stewart (Derby), Mr. Thursfield (Burnley), Mr. Wilmshurst (Halifax), Mr. Wordingham (Manchester); Mr. Wright (Brighton) in the chair. Letters of regret were received from Mr. Blackman (Aberdeen), Mr. Copland (Newport), Mr. Couzens (Exeter), Mr. Hamilton Kilgour (Cheltenham) and Mr. Talbot (Nottingham).

After full discussion the prospectus and constitution were passed as amended (with the exception of one or two points in the latter which stand over for consideration at the first convention), and it was decided, on the proposition of Mr. Arnot, that the municipal electrical engineers then present constitute themselves into the Municipal Electrical Association.

The following are the terms of the prospectus, describing concisely the motive and objects of the Association :—

(1.) The object of the Municipal Electrical Association is to promote the interests of municipal electrical undertakings, and to that end to bring municipal electrical engineers into relation one with another.

(2.) This Association will endeavour to promote the interests of municipal electrical undertakings, without regard to the source from which dangers threatening such interests may arise.

(3.) To secure consistent and well-organised management, the constitution provides for an Executive Committee, one-third going out of office after each annual convention.

(4.) The annual meeting of the Association for the discussion of Papers, the election of the executive, and the transaction of other business, will be held in May or June in each year, at such places as the Association shall determine, and on such dates as may be determined by the Executive Committee.

The following gentlemen form the Executive Committee and officers for the first annual convention, to be held in London on June 10th, 11th and 12th of this year :—

President.—Mr. Arthur Wright.

Vice-Presidents.—Mr. William Arnot, Mr. C. H. Wordingham.

Committee.—Mr. C. S. Vesey-Brown, Mr. Albert Gay, Mr. John Hesketh, Mr. A. B. Mountain, Mr. H. Faraday-Proctor, Mr. John H. Rider.

Hon. Treasurer.—Mr. G. H. Cottam.

Hon. Secretary.—Mr. Wm. L. Madgen.

Mr. Wright, Mr. Arnot and Mr. Wordingham, the President and Vice-Presidents for the year, are in charge of three of the most important municipal electric undertakings in the country, and, with the above-named Committee, are thoroughly representative of municipal electrical work. It was, on the proposition of Mr. Hesketh, seconded by Mr. Rider, unanimously carried that Mr. Madgen be asked to continue the honorary secretaryship until the convention, at which an official (probably a member) will be appointed. We understand that it is not improbable the convention of 1897 will be held in Manchester, and that of 1898 in Glasgow; but as to this nothing has yet been decided. In the meantime, however, steps are being taken by the Committee to make the first gathering a success.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

SPECIAL NOTICE.—The 1896 (fourteenth annual) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is NOW READY. The published price of the Directory and Handbook is 7s. 6d., post free 8s. 3d., abroad 9s. The book is greatly enlarged, is quite up-to-date, and includes the new Board of Trade Regulations issued February 6th.

NEW BOOKS AND EDITIONS.

The following New Books and Editions can be obtained of the Booksellers or direct from the Publishing Offices :—

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett *(now ready)*. Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"THE WORK OF HERTZ."—By Dr. O. J. Lodge, with many original illustrations, price 2s. 6d. nett, is now ready.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

"ELECTRIC MOTIVE POWER."—A new work, by Mr. Albion T. Snell with this title, is now ready, containing the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d. post free (abroad 11s.).

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by Messrs. W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—By Mr. F. Marten Weymouth is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

'THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"PRACTICAL NOTES FOR ELECTRICAL STUDENTS."—By Messrs. A. E. Kennelly and H. D. Wilkinson, price 6s. 6d., post free.

TENDERS INVITED.—The Corporation of Sunderland invite tenders for steam engines, continuous-current dynamos, water-tube boilers, fuel economiser, water-softening plant, and cast-iron tank. Tenders must be sent to Mr. Fras. M. Bowey, Town Clerk, not later than 5 p.m. on Friday, the 13th instant.

——— The Corporation of Bangor require tenders for the construction, supply and laying down of the necessary plant and mains for the installation and supply of electric current within the borough. The contracts are split up into two sections. Tenders must be sent in to Mr. W. H. Pritchard, Town Clerk, Bangor, by the 18th instant.

Digitized by Google

TENDERS INVITED.—Tenders are requested by Mr. George White-Fraser, consulting electrical engineer, of 18, Imperial Loan Building, Toronto, Canada, for generators and motors to a total capacity of about 1,000 H.P. of each, in various sizes. The machinery is to be installed in a large paper mill in Canada. Tenders should be forwarded promptly.

——— The Manchester, Sheffield and Lincolnshire Railway Company invite tenders for the supply, during the twelve months ending April 30, 1897, of various stores, including telegraph materials, wire, signal stores, fog signals, screws, rivets, asbestos packing, &c., &c. Tenders must be sent in by 10 a.m. on Tuesday, March 17th, to Mr. Oliver S. Holt, Secretary, London-road Station, Manchester.

——— Tenders are required for fitting up electric bells at the Infirmary of the Pontefract Union. Tenders by 4 p.m. to-day (Friday) to the Clerk (Mr. W. S. Wood), Union Offices, Pontefract.

——— The Rathmines and Rathgar Town Commissioners require tenders for the erection of telephones, &c. Particulars of the Township Engineer, Town Hall, and tenders by the 14th instant to Mr. F. P. Fawcett, secretary, Town Hall, Rathmines, Ireland.

——— The Police Department of the Corporation of Glasgow require a compound-wound dynamo for their sewage purification works at Dalmarnock. Tenders by the 14th instant to the Clerk, Mr. J. Lang, City Chambers, Glasgow.

——— The municipal authorities of Ecija require tenders for the concession for the electric lighting of the town for 20 years. Tenders to El Secretario del Ayuntamiento de Ecija (Seville), Spain, by the 10th inst.

——— Tenders are invited by the municipal authorities of Zamora for the concession for the electric lighting of the public streets for 20 years. Tenders to El Secretario del Ayuntamiento de Zamora (Leon), Spain, by the 30th inst.

——— The French authorities invite tenders for the supply of a quantity of telegraph paper, from 10mm. to 16mm. wide in 14 lots. Tenders to the Direction Générale des Postes et des Télégraphes, 103, Rue de Grenelle, Paris, by the 24th inst. Tenders are also required by the same department for the supply of eight lots of telegraph instruments. Tenders by the 25th inst.

——— The Erfurt Direction of the Prussian State Railways requires tenders for the supply of 52,000 arc lamp carbons. Tenders to the Königliche Eisenbahn Direction, 23, Bahnhof-strasse, Erfurt, by the 11th inst.

——— Tenders are required for lighting the suburban districts of Bucharest by some system which will not necessitate the employment of underground pipes. The districts are at present lighted by 3,265 oil lamps. The contract is for a term of five years, from April 13th, and specifications may be inspected at the offices of the Agence Havas, 96, Queen-street, Cheapside, E.C. Tenders to the Mairie by the 14th (26th) inst.

TENDERS ACCEPTED.—At the last meeting of the Blackpool Town Council, it was decided to approve the Electric Lighting Committee's decision to accept the tenders of Messrs. John Fraser and Son for boilers and condenser, Messrs. Tinkers (Limited) for steam pipes, &c., and Messrs. S. Z. de Ferranti (Limited) for a 300-kilowatt alternator and two 55-light rectifiers.

——— The Paving Committee of the Rochdale Corporation have accepted the tender of Messrs. Simpson Bros., for the supply of the electric lighting plant required at the sewage works, Roch Mills.

——— The Derby Town Council have accepted the tender of Messrs. J. Davis and Son for fixing electric bells and telephones at the Asylum, and connecting the porter's lodge by telephone with the main building, at £69.

——— The tender of Messrs. J. Brown and Co., of Sheffield, has been accepted by the Hampstead Vestry for the supply of two additional boilers (Ellis and Eaves' fire tube marine type) for their electricity works, at £3,500. Tenders were also received from Messrs. Willans and Robinson (Niclausse type), Maudslay, Sons and Field (Belleville water-tube), and J. I. Thornycroft and Co. (water-tube). The tenders of Messrs. Doulton and Co. for stone-ware pipes and traps; J. Gibb and Co., for tools, engineering stores, &c.; Sir W. A. Rose and Co., for oils; and the Wigan Coal and Iron Company, for coal, have also been accepted.

——— The Rhondda District Council have accepted the tender of Messrs. Treharne, owners of the Fernvale Brewery, to supply electric current for lighting main roads from Bridgend Hotel through Pontygwaith.

SALES BY AUCTION.—The Official Receiver in the bankruptcy of Charles F. Fox has instructed Messrs. Houldsworth and Son, of Northgate Hall, Halifax, to sell by auction, on Wednesday next, March 11th, at the Electrical Works, 1, Pond-street, Halifax, the plant and stock-in-trade, which includes a number of machines, lathes, tools, &c., and electrical fittings. Some further particulars are given in our advertisement columns.

APPOINTMENT VACANT.—The Uganda Railway Committee require an officer to take charge of the erection of telegraphs. Salary £400 per annum. Applications to the Secretary of the Committee, Foreign Office, Whitehall, London, S.W. Some further particulars are given in our advertisement columns.

BANKRUPTCIES.—A petition has been presented in the estate of John H. Cox, electrical engineer, 46, Kelly-street, and 13, Nicolson-street, Greenock. The examination takes place on the 13th inst., at the County-buildings, Greenock. Messrs. W. B. Paterson and Co., Glasgow, are agents.

——— In the failure of Charles F. Fox, described as electrical engineer and contractor, of 1, Bond-street, Halifax, the following are amongst the list of creditors:—

Cox Walkers	£91	0	0
Manchester Edison-Swan Company	76	13	3
Northern Electric Wire Company	42	1	6
Beecroft and Wightman	11	0	0

Liabilities amount to £544. 6s., and assets £343. 14s.

——— The following are the principal creditors in the failure of George Isaac Reakes, lately trading as an electrical engineer under the style of G. Reakes and Co., Bishop-street, Cherry Orchard, Shrewsbury:—

Manchester Edison-Swan Company	£232	0	0
Beanland, Perkin and Co.	36	0	0
Slade, Templeton and Co.	16	4	1
General Electric Company	16	0	0
Evered and Co.	13	18	6

LIQUIDATIONS.—At an extraordinary general meeting of the shareholders of the Morecambe Electric Light and Power Company (Limited), on February 27th, it was decided to wind up the Company voluntarily. The Chairman (Mr. W. B. Hodgson) said the meeting was called in consequence of the petition recently presented for the compulsory winding up of the Company by the Bank of Liverpool; but the petitioners intimated that they would not proceed with their petition in the event of the Company deciding to go into voluntary liquidation. It was decided to appoint Mr. C. R. Compston, of Lancaster, as liquidator. The non-success of the undertaking is attributed to insufficiency of capital and to the result of proceedings by residents in the vicinity of the generating station for nuisance and other unforeseen difficulties. The District Council recently decided to purchase this Company's undertaking.

——— Creditors of the Automatic Electric Light Syndicate, Limited (in voluntary liquidation), must send in particulars of their debts or claims to the liquidator (Mr. J. M. Tourtel), 22, Long-lane, Aldersgate-street, E.C., by April 10th.

——— Creditors of the Electric Novelty Syndicate, Limited (in voluntary liquidation), are requested to send in particulars of their debts or claims to the liquidator (Mr. Geo. F. Haskins), 18, Walbrook, E.C., by April 20th.

——— A meeting is to be held at Winchester House, Old Broad-street, E.C., on the 31st inst., at 2:30 p.m., to receive an account of the winding-up of the Johannesburg Lighting Company (Limited).

PRITCHETT ACCUMULATORS.—Messrs. Venner and Sillar, of 10, Delahay-street, Westminster, have been appointed by Messrs. Pritchett and Gold sole agents in Great Britain and Ireland for the Pritchett Accumulators.

BUSINESS CHANGES.—Mr. A. H. Rose has joined the firm of Rose and Bird (Limited), manufacturers of the "Radiant" Incandescent lamp, in the capacity of managing director, the position occupied by the late Mr. J. A. Bird. The offices of the firm have been removed from Newgate-street, to Albany-buildings, Victoria-street, Westminster, S.W.

BERGHANSEN'S POLE FINDER.—Mr. R. Simon, of Zulla-road, Nottingham, sends us a copy of a recent report by Prof. W. Robinson upon this handy instrument, particulars of which were given in our issue of December 20th last. Prof. Robinson's report is to the effect that the pole finder is "quick in action and very sensitive, giving a good deposit of red-coloured crystals in less than a minute with a cell of two volts pressure." The weight of the pole finder is 2oz. and its length 3¼in. A large number (over 1,000) have already been sold.

NEW CATALOGUE.—An excellent and very complete catalogue of electrical apparatus and accessories reaches us from Messrs. Dorman and Smith, of Ordsal Works, Salford, Manchester, copies of which can be obtained at the London offices, 94, Charing Cross-road, W.C., or at 56, George-square, Glasgow. The illustrations are well executed, and are designed to afford the trade every facility in selecting their requirements. Nearly 200 examples of apparatus, fittings and accessories are shown, including switchboards, a variety of switches, a considerable variety of lamp-holders, suspension holders, reflectors and shades, cut-outs, distributing boxes, wall sockets (including new designs for concentric work), socket connectors, ceiling roses and suspension pendants. In mill and ships' fittings for the electric light a good selection is presented.

Digitized by Google

The whole of the goods included in the list are actually manufactured by the firm. Useful information regarding all the apparatus is given, and these particulars are accompanied in all cases by prices. The catalogue is well arranged, clearly printed, and in fact a very useful and timely publication.

CATALOGUES.—In our February 14th issue we noticed Section A catalogue and price list from Messrs. P. R. Jackson and Co. (Limited), of the Salford Rolling Mills, Manchester. We have now to acknowledge the receipt of Section B, dealing with piston, pump and packing rings, in the manufacture of which this firm holds a high reputation. Particulars of a large variety of these rings is given in the list.

THE NEW ELECTRIC SUPPLY STATION AT BUDAPEST.—A detailed description of this station, compiled by M. Etienne de Fodor, the Director of the Company, has just been published in brochure form. It contains 22 splendid illustrations and three tables of useful data, and is printed on fine paper. In *The Electrician* of July 26, 1895, we gave a description of this station.

"ARCHITECTURE."—Under this title a monthly magazine of architectural art has recently been started, and the second number, which has just come to hand, contains a quantity of excellent reading matter, accompanied by some exceptionally good illustrations. The publishing offices are at Talbot House, Arundel-street, Strand, and the price of the magazine is 1s.

BERLIN INDUSTRIAL EXHIBITION.—Amongst the features of this Exhibition will be the general assembly of the Union of German Railway Administrations, representing the railway companies of Germany, Austria-Hungary, the Netherlands, Roumania, Belgium, and the Berlin-Warsaw Railway; the Congress of the German Electrotechnical Society and of the Society of German Architect and Engineers, the German Society of Mechanics and Optics and of the German Photographic Association. The important question of the selection of a competent jury has been discussed, and it has been decided that exhibitors in the different sections are to appoint the judges to whom the granting of awards will be entrusted.

ABERDEEN.—The question of the extension of the electricity station was under consideration by the Gas and Electric Lighting Committee at its last meeting. It was pointed out that before next winter it would be necessary to put down additional plant, and very large extensions would be required at an early date. In the meantime it was thought desirable to obtain another 300 H.P. engine. It was resolved to obtain a report as to purchasing a new engine, and generally on the whole question of extensions. The report is to be presented at an early meeting of the Committee. ——The Harbour Board are making inquiries as to the cost of lighting the harbour electrically, and for the purpose of obtaining information a deputation from the Board recently visited Leith, where the harbour has been lighted electrically for some time. It is stated that the Board will, in the event of electric lighting being decided upon, take current from the Corporation.

ALLEGED EMBEZZLEMENT.—At the Blackpool Police Court, on the 27th ult., a man named Peter Bradley was charged with embezzling sums of money amounting to about £18 from his employers, Messrs. Sharp and Kent. It was stated that Bradley had acted as agent for the prosecutors, but had not accounted for the moneys which had been paid to him. The defence was that there was a dispute between the parties, and that the prosecutors were indebted to the prisoner in a much larger sum than the amount alleged to have been embezzled. The prisoner was remanded for a week.

ASTON.—Mr. Vaudrey has presented his report to the District Council on the condition of the electric light installation at the Baths, Free Library and Council Buildings. The report recommends the putting down of a new engine and dynamo, and these the Highways and Buildings Committee have now been authorised to purchase at an estimated cost of £350.

AYR.—A special meeting of the Town Council was held on Monday last for the purpose of considering a recommendation by Mr. R. Hammond, consulting electrical engineer to the Council, that new transformers be purchased at a cost of £630, those originally supplied being deemed too small for their work. An animated debate occurred, but it was resolved to delay decision in the matter.

BANGOR.—At the meeting of the City Council on Wednesday a long and acrimonious discussion arose on the minutes of the Electric Light Committee. The minority of the Council is doing its utmost to thwart and delay the introduction of the electric light, and a petition against the project has been presented to the Board of Trade. The Committee's replies to the statements contained in the petition have also been forwarded to the Board. The minutes were approved.

BELPER.—A discussion on the electric lighting question was initiated by Mr. Smedley ut the last meeting of the District Council. He moved that an application be made to the Board of Trade for a Provisional Order. The question was adjourned till the April meeting of the Council.

BLACKPOOL.—The Town Council on Tuesday last approved the proceedings of the Electric Lighting Committee recommending the application to the Local Government Board for sanction to borrow a further sum of £30,000 for extensions to the electricity works.

BRADFORD.—The Electricity Committee have decided to lay electric light mains on the west side of Manningham-lane as far as Queen's-road, and also in Little Horton-lane. The Committee have approved the specifications of plant required for the new electric supply works, and it was resolved to issue advertisements inviting tenders for same.

BRAY.—At the last meeting of the Town Commissioners the resident engineer at the electric light station (Mr. G. M. Harriss) presented a lengthy report on the condition of the plant, and recommended the Commissioners to make additions thereto. The question was allowed to remain in abeyance until an independent report has been obtained from a consulting electrical engineer, and Mr. R. Hammond has been appointed by the Commissioners to prepare a special report on the matter.

BRISTOL.—The Joint Committee of the Sanitary and Electrical Committees, recently appointed to consider the question of sanctioning the introduction of the overhead system of electric traction into the city have decided to obtain the opinion of an expert as to the most suitable system. The Electrical Committee are considering the advisability of extending the electric light mains to Stoke's Croft and North-street. The accounts of the Department for the year ended December 31st show a gross profit of £4,019. 19s. 10d., as compared with £456. 7s. 11d. in 1894. During the year 251,708 units were supplied to private consumers and 156,893 for public lighting.

BURTON-ON-TRENT.—At the meeting of the Town Council on Tuesday the Gas and Electric Lighting Committee reported that the accounts of the lighting department for the past year show a deficiency of £292. 0s. 5d. The total capital expenditure to date is £28,634. 12s.

CABUL (AFGHANISTAN).—According to an Indian exchange, Sir Salter Pyne, who acts in a consulting capacity to the Ameer on military and other engineering matters, is on his way home with presents for Her Majesty and with appointments in his pocket for British electricians to proceed to Cabul to instal the electric light, not only in the palace but in the streets of the city. It is further stated that the work is to be entirely carried out with British plant and material.

CAMBERWELL (LONDON).—The Special Electric Lighting Committee have presented their report on the application of the County of London and Brush Provincial Company for a Provisional Order for the district. The report sets forth the terms upon which consent should be given, and gave rise to a lengthy discussion at the last meeting of the Vestry, some of the members contending that the application should be opposed. Eventually the Committee's recommendations were agreed to.

CARDIFF.—The tenants of the Royal Arcade are anxious to avail themselves of the advantages of the electric light, and the owners of the arcade have, for some time past, been negotiating with the Lighting Committee for a supply of electric current. The chief obstacle in the way of introducing the light is the cost of repaving the arcade after the laying down of the electric light main. The Public Works and Lighting Committees have each offered to contribute a quarter of the cost of the pavement, and it is hoped that this concession will get over the difficulty with the Arcade Company, as there is likely to be a considerable demand for current from the tenants, several of them having already sent in applications.

COLCHESTER.—The Town Council has received a letter from the commanding officer of the Royal Engineers (Eastern District) to the effect that the War Department would be prepared to take current for the electric lighting of the block of officers' quarters, the officers' mess and the recreation buildings in the new barracks. Before coming to any decision as to lighting the whole of the barracks by electricity, the result of experiments being made elsewhere must be awaited.

COMMISSION OF SEWERS.—At the last meeting of the Commissioners of Sewers, in reply to a question as to when the experiments in the electric lighting of the side streets would be commenced, Mr. Voysey (the electrical inspector) said it depended upon the City of London Company. The apparatus was complete, and the experiments would be commenced in about six weeks.

CORK.—The Cork Electric Tramways Company (Limited) have decided to apply to the Lord Lieutenant in Council, under the Tramways (Ireland) Acts, for an Order in Council authorising the construction, working and maintenance of tramways in the city and county of Cork. The Company intend to reserve power to adopt electricity or other mechanical power on the proposed tramways.

DERBY AND ASHBOURNE TRAMWAY.—It is stated that the Bill for the construction of an electric tramway between Derby and Ashbourne at an estimated cost of £31,000 has been abandoned.

Digitized by Google

DUBLIN.—The accounts of the Electric Light Department for the year *1894* were submitted at the last meeting of the City Council. The Electric Light Committee reported that, after paying out working expenses, interest, &c., and putting aside £1,846 for sinking fund purposes, there was sufficient profit to pay a dividend of 6 per cent. on the capital expenditure. It was stated that there was considerable difficulty in keeping pace with the demand for current. The Committee have at present applications from 80 customers for an equivalent of about 6,000 8 c.p. lamps, which they were unable to supply. After a lengthy discussion the accounts were approved, but the Committee were asked to show a little more alacrity in the presentation of their reports.——The Corporation have considered the report of the Committee of the whole Council on the Bill of the Dublin Southern District Tramways Company, and with regard to wayleaves, &c., for their proposed system of electric tramways, and also a report as to certain proposals by the Dublin United Company. The first report recommended that the scheme of the Southern Company for the construction of about 13 miles of tramway be approved, and that the rent be fixed at £4,000 per annum. Mr. Alderman Meade moved the adoption of the first report. After a five-hours debate it was decided to postpone the further consideration of the matter for six months. A further amendment approving the construction of No. 1 line of the Southern Company from Haddington-road to O'Connell Bridge was carried.

DUNDEE.—The National Telephone Company have under consideration the question of making certain alterations to and improvements in the telephone exchange at Dundee, including the introduction of the twin wire system. The Company require that the town trunk wires should be placed underground.

EALING.—The District Council have decided to have plans, &c., prepared for the extension of the electricity works. At the last meeting of the Council the Chairman stated that the demand for current had been much greater than was at first anticipated, and they would shortly have to put down additional machinery at the generating station.

ECCLES.—A long discussion arose at the last meeting of the Town Council on the minutes of the Town Hall and Electric Lighting Committee. Extracts were given from Mr. W. H. Preece's recent report to the Swansea Town Council, and the Committee recommended the Council to proceed with their joint electric lighting and refuse destructor scheme. Alderman Spary was in favour of postponing the matter, as he said they would shortly have the tramways on their hands, and the question of electric traction should be considered in conjunction with the electric lighting and dust destruction schemes. The minutes were eventually approved.

EDINBURGH.—Notice of motion has been given for the next meeting of the Council that it be remitted to the Electric Lighting Committee to consider whether it was not desirable to have the consulting electrical engineer appointed a permanent official of the Corporation to advise on all points in regard to installation, and to report.——Recommendations by the Cleaning and Lighting Committee that no action should be taken in regard to the electric lighting of the remaining public thoroughfares in the city as defined by the tramway routes, and that also no action should be taken for lighting by electricity the West Port, were discussed at the last meeting of the City Council, and a compromise arrived at in the first case, and in the second a direct negative was approved. At the next meeting further extensions of the electric lighting mains will be discussed.——The Town Council have considered a letter from Messrs. Walter Dixon and Co., electrical engineers, of Glasgow, on the subject of adopting a system of electric traction on the tramways, hut have decided to take no action in the matter, and the Tramways Committee's report was approved.

FAREHAM.—A special meeting of the Town Council was held last week for the purpose of further considering the electric lighting question. In compliance with a request from the Board of Trade, the Council have passed a resolution undertaking within three months of taking over the Electric Lighting Company's plant to place the wires underground. It has been decided to engage Mr. E. Manville to prepare a report on the present condition of the plant and as to necessary extensions, &c. The Council have accepted the offer of the Capital and Counties Bank to lend £6,681 at 3 per cent. for 20 years for electric lighting purposes. The 17th inst. has been fixed as the date for the completion of the purchase of the Fareham Company's works, and a satisfactory arrangement has been come to as to the payment of interest on the purchase money from the date of the original contract to purchase, and also as to costs in the recent action. All's well that ends well.

GLASGOW.—The National Telephone Company have applied to the Corporation for leave to lay their wires underground. The matter has been referred to the Finance Committee.

HANLEY.—At the special meeting of the Town Council on Wednesday the General Purposes Committee recommended that, as from 1st January last, the charges for electric current be as follows:—5d per unit to general consumers, 4d. for places of worship, and 3d. for motive power purposes; and that, in lieu of the discount of 5 per cent. hitherto allowed, an abatement of 1½d. per unit be made on accounts paid within 21 days from the end of the quarter. The recommendations of the Committee were confirmed, with the exception of that relating to discounts.

HALIFAX.—The Markets Committee have decided to wire the new markets for the electric light. The work is to be carried out under the supervision of the Borough Electrical Engineer, Mr. T. P. Wilmshurst. It has also been decided to wire the Town Hall. The Lighting Committee have decided to recommend the Town Council to apply for sanction to borrow a further sum of £20,000 for electric lighting purposes.

HAMPSTEAD (LONDON).—The Vestry have decided to lay additional electric light mains to Shoot-up-Hill and Adamson-roads. Messrs. J. Brown and Co. have been requested to estimate for pumps, blow-off tank, pipes, &c., required for the electricity works.

KING'S NORTON.—At the meeting of the Board of Guardians on Tuesday the House Committee reported that they had invited tenders from six firms for the electric lighting of the new infirmary and workhouse.

LECTURES.—At a recent meeting of the Midland Institute Scientific Society, at the Technical School, Dr. Sumpner (principal of the school) lectured on "Some Curiosities of Magnetism." The lecturer said it was a curious fact about engineering industries that they seemed entirely dependent on the existence of a few substances. In the electrical industries copper had to be used for conductors, and nothing but carbon would do for glow lamps and arc lamps; lead, though the heaviest and least convenient of ordinary metals, had to be used for secondary batteries, while no metal but iron would at all do for dynamos and motors. All substances except iron, nickel and cobalt were so alike in magnetic properties that they differed among themselves to a much less extent than the stature of ordinary persons, but to represent the magnetism of iron in the same way they would have to imagine a race of men as tall as the Matterhorn. A number of experiments with magnetic needles were shown illustrating the behaviour of iron when subjected to magnetic forces. Magnetism was far more wonderful than the new X-rays, for it could traverse both flesh and bone, while the X-rays could only get through flesh. Dr. Sumpner was thanked for his lecture.

——— An interesting lecture on "Recent Improvements and Applications in Electrical Machinery for Power-Transmission Purposes" was delivered by Mr. Walter Dixon, at Gordon's College, Aberdeen, on Tuesday evening last.

LEEDS.—The City Council have approved the minutes of the Highways Committee, recommending the adoption of the overhead trolley system of traction for the entire tramway system of the city.

LIVERPOOL.—A complete system of telephonic connection between the Dale-street Central Police Office and the various police stations in the city has been established. The head constable, by way of experiment, has adopted the "individual" system of signalling in case of the outbreak of fire, the occurrence of an accident, or the need of police assistance in any way. The National Company have fitted up at the Dale-street detective office instruments which afford immediate communication with a number of points by special connection with the ordinary telephonic circuit. Under this arrangement, as necessity arises, a constable unlocks the box containing the apparatus, say at the Haymarket, and conveys his message to the head office. Here there is a recorder, upon which is printed in cipher the exact locality whence the message originated and the nature of the assistance required.——The Lighting Committee have decided to recommend the City Council to apply, under the Liverpool Electric Supply (Transfer) Bill, for powers to increase the amount to be borrowed to £500,000 in order to provide capital for extensions.——At the meeting of the City Council on Wednesday it was decided to approve the report of the Finance Committee, which recommended that the public buildings be lighted electrically at a cost not exceeding £5,500.

MACROOM (CORK).—A meeting of the most influential inhabitants was recently held, when it was decided to take steps to put the town under the Town's Improvement Act, the ultimate object in view being the introduction of the electric light.

MAIDSTONE.—The proposed transfer of the Maidstone Provisional Order to Mr. Thomas King was again discussed at the last meeting of the Council. Some time ago the Electric Lighting Committee presented a report recommending the transfer, but at a recent meeting of ratepayers a resolution deprecating the suggested sale was passed. Mr. Alderman Ellis now moved the adoption of the Committee's report, and said that Mr. King had increased his original offer for the Order by £250. Mr. Cox moved an amendment that the report be referred back. Mr. Morling, in seconding, suggested that the Council should employ an electrical expert who would be able to advise them as to the best course to pursue. He thought that the Council would be able to supply

Digitized by Google

electric current at a much cheaper rate than a company, and this was an important matter to private consumers. After an animated discussion, the amendment was carried by 12 votes to 8.

MANCHESTER SHIP CANAL.—In the course of his remarks at the Ship Canal Company last week, Mr J. K. Bythell, the Chairman, said that among the works to be finished during the current year, and included in the capital expenditure of £48,620, was a new electric lighting installation.

MORECAMBE.—A meeting of ratepayers to consider the question of the proposed purchase of the Morecambe Electric Light and Power Company's undertaking by the District Council was held last week. The Clerk stated that the Board of Trade had already intimated their willingness to consent to the transfer of the Company's Provisional Order. The total cost of an installation for public and private lighting was estimated at £16,000, inclusive of £3,950 to be paid for the mains. A resolution approving of the Council's decision to purchase was duly passed.

MUCH WOOLTON.—The Urban District Council have decided to oppose the application of the Liverpool District Lighting Company for a Provisional Electric Lighting Order, and have resolved to take the necessary steps to obtain an Order to enable the Council to supply electric current.

NEWMARKET.—The Board of Trade have written to the District Council for their observations on the application of the Newmarket Electric Light Company for a Provisional Order. The Council have instructed the Surveyor to prepare a report on the matter.

NORTHAMPTON.—The Directors of the Northampton Electric Light and Power Company have decided to make reductions in the price of current, and to adopt the Wright system of charging.

NOTTINGHAM.—At their meeting on Monday the Town Council considered the report recently presented by the Electric Lighting Committee, an abstract of which appeared in our last issue. The report recommended the Council to borrow an additional sum of £40,000 for electric lighting extensions. The Chairman of the Electric Lighting Committee (Sir John Turney), in moving its adoption, said that it was absolutely necessary to considerably extend their supply station and to put down additional plant. The increase in the demand for electric current was most gratifying, and had exceeded their anticipations. In conclusion, he said they could not afford to lose any time, as he had that morning seen a letter to the Electric Light Committee from the builders of the engines employed at the station (Messrs. Willans and Robinson), stating, in effect, that owing to the constant flow of orders during the past few months, the capacity of their existing works was taxed to its fullest extent. He, therefore, asked that the Committee should be allowed to proceed with the work immediately. After a brief discussion this course was approved, and the Committee's report adopted.

RIPON.—A long discussion on the electric lighting question took place at the last meeting of the City Council. For the guidance of the Gas Committee, it was decided to instruct the Town Clerk to obtain from the Dean and Chapter information as to the number of lights they would require in the event of their deciding to light the Cathedral electrically.

SALFORD.—At their meeting on Wednesday the Town Council decided to apply to the Local Government Board for sanction to borrow an additional sum of £5,000 for electric lighting purposes.

SOUTH AFRICAN EXPORTS.—For the week ended February 22nd, goods classed under the heading "Electrical" were exported from this country to South Africa of the value of £3,650, made up as follows:—Cape Town, £613; Algoa Bay, £127; East London, £5,429; Natal, £481.

ST. GEORGE (BRISTOL).—The District Council have consented to the proposal of the Bristol Tramways Company to extend their electric tramways along the road at the parish boundary between Euston-road to Barton Regis Union.

ST. GILES (LONDON).—The new public library is to be wired for the electric light. The contract for the fittings, &c., has been placed with Messrs. S. Pontifex and Co., of Coleman-street, E.C.

ST. HELENS.—The Corporation have approved the plans and specifications of the buildings for the electric light works, and the engineer has been instructed to obtain tenders.

STAFFORD.—The Gas and Electricity Committee reported at Tuesday's meeting of the Town Council that they had entered into an agreement with the County Council for lighting the Council buildings, the Judge's House and Eastgate House electrically at an annual charge of £175, the County Council paying at the rate of 8d. per unit for current supplied over 1,300 units per quarter, and the lamps not to exceed an equivalent of 1,200 8 c.p. The Committee's minutes were approved.

THEATRE LIGHTING.—It is proposed to fit up the Folly Theatre, Manchester, for the electric light.

TIPTON.—The electric light has just been installed at the Rattlechain Brickworks. Incandescents are used for interior lighting, but the large marl hole and wharf are illuminated by means of two 2,000 c.p. arcs. The contract was executed by a local electrical engineer, Mr. J. Oxham.

TRAIN LIGHTING.—The Waterford and Limerick and Western Railway of Ireland is making some experiments as to the suitability of the electric light for train lighting, and Messrs. J. Stone and Co. have been employed to fit up one of the carriages on the line.

WAKEFIELD.—The Electric Light Committee have decided to recommend the Council to at once proceed with their electric lighting scheme. The Council have already obtained sanction for borrowing the necessary money, and tenders have been accepted for plant, &c.

WELLS.—At the last meeting of the Town Council it was decided to apply to the Local Government Board for sanction to borrow £10,000 for the establishment of electric light works in the town.

WEST HAM.—An attempt made by Mr. Alderman Smith to delay indefinitely the consideration of electric lighting matters was rejected at the last meeting of the Town Council. This course, however, does not place electric lighting matters in this district on any more satisfactory basis.

COMPANIES' MEETINGS AND REPORTS.

Telegraph Construction and Maintenance Company (Limited).

The thirty-second ordinary general meeting of the members of this Company was held on Tuesday, at the offices, Old Broad-street, under the presidency of Admiral Sir George H. Richards, K.C.B., F.R.S.

The SOLICITOR (Mr. Chapman) read the notice convening the meeting, and other routine business having been disposed of,

The CHAIRMAN said: I have no doubt that you will have seen from the report that it is comparatively an unusual one, as it is rather a meagre record of work done during 1895. I daresay that those who were here will remember that at our last annual meeting, and again at the July meeting, I shadowed forth that there were no great works in progress, and that prediction has been realised. As a matter of fact, there has been really very little submarine telegraph work carried out during 1895, and I think I am correct in saying that a great part of what has been done has been executed by this Company. This, to a certain extent, is satisfactory to us all; but our share in the work has been, as you will see by the report, a few hundred miles of cable for the Japanese Government, which we have sent to Japan, and a few hundred miles for different companies. We have also made several repairs in existing lines of cable, and our ordinary guttapercha work has been fairly good, and compares favourably with that done in the previous year. Still, this has not enabled us to pay you the dividend which we have done for a great many years, and we regret that as much as you can. We are, however, proposing to-day to pay you a dividend of 10 per cent., which, added to the interim distribution already paid, makes 15 per cent. for the year, or £1. 16s. a share. Like other companies, we must sometimes expect to have a lean year, and we have had one in the period under review; but I am able to tell you that as far as the Company's position goes, it is entirely sound financially, and very healthy. We only want work. We are not very often, as you know, without work, and I think I may say that our prospects of work for this year are better. We have great hopes that that will prove to be so. I am glad to tell you also that all our works, factories, machinery and ships are in good order, and we were never in a better position to carry out work than we are in now. I do not know that I can give you any further details. These are the facts, and I think I had better now move the first resolution. If any gentleman has any questions to put to me afterwards I shall be very pleased, as far as I can, to answer them. I will now move—

"*That the report and accounts of the Directors to December 31, 1895, submitted to this meeting, be and the same are hereby received and adopted, and that a dividend of 2½s. per share, in addition to the 12s. per share interim dividend paid on June 30, 1895, be paid on all shares of the Company for the year ended December 31, 1895, and that such dividend be paid free of income tax.*"

Sir ROBERT G. W. HERBERT, G.C.B., briefly expressed his pleasure in seconding the resolution.

Gen. TREVOR inquired where they got their dividend of 15 per cent. from for the past year. He made out that the earnings were between 5 and 6 per cent on the capital.

The CHAIRMAN: 15 per cent. is on the paid-up capital of £448,200.

Gen. TREVOR said that in addition to the share capital there were debentures amounting to £150,000 and the reserved fund of £50,000, making altogether £640,000. That was their trading capital, and on this they had made a profit of £32,500, which was nothing like 15 per cent. He only wanted to know where the rest came from.

The CHAIRMAN: Our profit is made out of the work done. The money you speak of consists of reserves which we are empowered to make for certain purposes, and which it is essential for a Company of this kind, which has many risks, to possess. That money is your security. On the other side it is amply met by good securities, showing the prosperity of the Company.

Digitized by Google

Gen. TREVOR inquired whether he was correct in stating that the earnings for the past year had been under 6 per cent. on the capital.

Sir ROBERT HERBERT: That is after charging 5 per cent. on the debentures.

Mr. GEORGE W. CAMPBELL: A certain amount is taken from the profit and loss account of last year. The balance brought from last year's account has been reduced in order to make up the dividend.

Mr. WHISH said the debts owing to the Company amounted to the large sum of £318,000 odd, and it was to be hoped that they were good, sound debts.

The CHAIRMAN: There is not the least doubt about them. They are perfectly good, as are also our securities. You have your accountants and your auditors here, and I am sure that they will testify to that if necessary. You have, however, always accepted our word in these matters. We have no reason whatever for keeping anything from you except what we must keep from you as a trading company, because we cannot make everything public regarding our affairs. He then put the motion, which was carried. Subsequently he proposed the re-election as Directors of Mr. James Pender and Sir Robert Herbert.

Mr. CAMPBELL seconded the motion, which was carried unanimously.

Mr. GIBSON afterwards proposed, and Mr. HEWAT seconded, the re-election of the auditors, Mr. John Gane and Mr. P. A. Glegg, and the resolution was carried unanimously.

Gen. TREVOR then proposed a vote of thanks to the Chairman and Directors for their attention to the Company's affairs.

Mr. CROFT seconded the motion, which was carried unanimously.

The CHAIRMAN: We are much obliged to you for the confidence you continue to maintain in us.

The proceedings then terminated.

Chelsea Electricity Supply Company (Limited).

The annual ordinary general meeting of the Company was held on Wednesday at their central station, Cadogan-gardens, under the presidency of Mr. J. Irving Courtenay.

The SECRETARY (Mr. S. J. Cluer), having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, I assume that the Directors' report and the audited accounts for the year 1895, which have been circulated among the shareholders, may be taken as read, and I shall therefore proceed at once to make a few remarks on the principal points of interest in the Company's affairs during the year under review. We have, as you will have seen in the report, issued £60,000 Four and a-Half per Cent. Debenture stock, and the remaining 3,723 Ordinary shares have also been placed. Only a portion of this is additional capital, because we have redeemed the whole of the Six per Cent. Debentures, amounting to £36,900. The greater part, however, of the shares and Debenture stock was not paid up until the latter part of the year, and most of the fresh capital expenditure (£41,176. 4s. 6d.) was made during the same period, so that the normal return on this new capital could not possibly be earned in 1895. In July last we lowered the charge for current by 25 per cent., and consequently the increase in revenue may not seem so large as might have been expected. Notwithstanding this reduction, the increase over the previous year in net revenue from £3,991. 11s. 5d. to £6,414. 16s. 5d. enables us to recommend the same rate of dividend on the Ordinary shares, *i.e.*, 5 per cent., as that paid last year, although the sum required for this dividend, together with the interest on Debentures, exceeds that distributed for 1894 by nearly £3,000. We propose to carry forward £1,114. 16s. 5d. to next account. We have again reduced the cost of production. We have also had a considerable increase (over 10,000) in the number of lamps supplied, and I may add that this increase still continues, even to a larger extent than last year. We look for an improvement in the yield per lamp fixed owing to the growing though slow adoption of the electric light in the shop district. This brings me to the question of capital expenditure. An increase of lamps means additional mains, plant, and machinery, and we have not only largely increased our plant, but have already begun to provide for the increase of customers expected during the present year, and thus be ready for next winter. The continued expansion of the business creates a recurring need for fresh capital, for we only raise additional capital, and increase our plant and mains, from time to time as wanted. We have during the past year completely altered and equipped the new generating station in Manor-street, called the Cheyne-walk station, and a new storage station for the supply of the Fulham-road district is in course of erection, and will shortly be completed. There have been added to the plant at the generating station in Manor-street five steam boilers and eight engine dynamos of 150 H.P. each and one of 90 H.P., and six continuous-current transformers, each having a capacity of over 2,000 lights, are installed in our sub stations. We have laid street works for a distance of about 8,000 yards, the cases in which have a capacity for accommodating about 40,000 yards of mains, the conductors actually laid during the year having a length of about 29,000 yards. It is a very difficult matter in a thickly-populated neighbourhood to obtain land where it is wanted and when it is wanted, on which to make extensions, or to build new stations. The Directors have, therefore, been looking ahead, and have secured the freehold of a large plot of land surrounding and including the land on which our Cheyne-walk generating station stands. The fact that the Company owns the freehold of this land cannot but be advantageous. You will have seen from the reports in the newspapers that an injunction has been granted against the Company in respect of the generating station here in Cadogan-gardens. I hope we shall shortly be in a position to deal with this troublesome matter in a manner that will put an end to further litigation. I may here remark that electric lighting companies have had hard measure dealt out to them by the legislature. Perhaps it is to some extent their own fault, because those who took a leading part as their representatives at the time did not forsee the oppressive use that would be made of certain clauses in the Electric Lighting Acts. The electric light supply companies carry on a *bonâ fide* and necessary industry to the great benefit of the public, and with as yet only moderate returns to their shareholders for the risks they have run. They have statutory duties to fulfil, but they are, in my opinion, without adequate legal protection, and are considered as fair game to be shot at; the alternatives generally presented to them being either to purchase peace at any price the occupier of adjoining property chooses to demand, or to run the risk of being forced to discontinue the full use of premises upon which a large capital has probably been spent. The attention of Parliament will, I learn, be soon directed to this most important question. The companies only ask for fair treatment. They do not object to pay liberal compensation, if, in spite of every effort on their part, any real annoyance should be caused to their neighbours, but they will ask to be protected by Parliament against being coerced into paying unreasonable sums. There have been during 1895, from several causes, exceptional duties and responsibilities of a most anxious character thrown upon the managing engineer, Mr. Frank King, our resident engineer, Mr. Percy Still, and the staff, and I cannot permit this occasion to pass without expressing our thanks and appreciation of the manner in which they have discharged those duties. You will see from our net revenue account that we have written off all the expense incurred in connection with the proceedings I have mentioned above. We have also placed £1,047. 6s. 7d. to a reserve fund, and carried forward £1,114. 16s. 5d. In view of all the circumstances and the difficulties with which the Company has had to contend, and still has, in carrying on its business, I consider the general result to be satisfactory, and it is evident that its financial position has been greatly strengthened since our last meeting. With these observations I will move:—

"*That the report of the Directors and the statement of accounts for the year 1895, now before the meeting, be and they are hereby adopted; and that the payment of a dividend of 6 per cent. on the Preference share capital and of 5 per cent. on the Ordinary share capital for the year 1895 be and is hereby approved, payable forthwith.*"

The DEPUTY-CHAIRMAN (Major-Gen. Webber, C.B.), in seconding the motion, observed that the career of a Company like the Chelsea, once it was established on the lines which experience had recommended for continuance, would be a very simple matter indeed but for the various conditions which surrounded its development. The one to which the Chairman had alluded had given him and the Directors considerable anxiety during the year, not as to their power to overcome the difficulty that arose, but on the very point which the Chairman had mentioned—namely, that electric light companies were entirely inadequately protected from those who wished to take advantage of the situation which the law ought never to have created. The *modus operandi* of the Company was so distinctly laid down and assured, he might say, from a technical and engineering point of view, that there was nothing to describe on the present occasion which they were not already aware of from information which had been given to them in past years. The Chairman had not said a word too much respecting the admirable work done by their officers, but Mr. Courtenay had not alluded to the very admirable work which he had himself done during the past year. It had rarely been his (the speaker's) lot to meet anyone who, filling such a position as Mr. Courtenay did in the Chelsea Company, gave so much of his valuable time, and in a way which was of enormous benefit, to the Company as their Chairman did.

The CHAIRMAN then invited discussion, but no question being asked, he put the resolution, which was carried unanimously. He afterwards proposed the re-election as a Director of Mr. Nugent Daniell.

Mr. G. N. MARTEN seconded the resolution, which was carried unanimously.

On the motion of the CHAIRMAN, seconded by Mr. MARTEN, Mr. Emile Garcké was also re-elected to his seat at the Board.

General MACKENZIE, in proposing the re-election of the auditors, Messrs. Cooper Bros. and Co., said he desired to take that opportunity of expressing on behalf of a considerable number of shareholders their gratification with the admirable report which the Board had been able to present. They were in no degree anxious that the Directors should increase the dividend so long as they maintained the present good position and extended the valuable business of the Company.

Mr. FRANK KING seconded the motion, which was carried unanimously.

The CHAIRMAN: That concludes the business. I have only to say how gratified we all feel that we are able to present a report so good as to warrant the remarks made by General Mackenzie, and to tell him that the Board will bear in mind the remark which he made on his own account and that of other shareholders—that what is desired is not that we should pay you large dividends, but fair and moderate dividends, and to consolidate the position of the Company.

The proceedings then terminated.

Hove Electric Lighting Company (Limited).

The fourth annual meeting of this Company was held on Wednesday at Cannon-street Hotel, Colonel A. J. Filgate, R.E. (Chairman), presiding.

The SECRETARY (Mr. F. R. Reeves) read the notice calling the meeting.

The CHAIRMAN said: The report is a very full one, and gives a fair exposition of the Company's work and present position, which I trust you will consider satisfactory. The total capital expenditure up to December 31, 1895, amounted to £57,472, against £48,828 at the close of 1894, and since the accounts were made up our capital commitments have been

Digitized by Google

further augmented by about £2,000. We have been obliged, as stated in the report, to obtain a new Crompton-Willans set of 250 H.P., thus increasing our dynamo horse-power to 700; and two new boilers aggregating 380 H.P., increasing our nominal boiler power to 780. This addition was necessary, as our resident engineer found it difficult to contend with the heavy demand thrown on the generating station last December. We have also erected an economiser by the use of which we hope to effect a saving on our coal bill, which is at present a large item. With these additions to our plant we shall be able to meet a heavier demand for current than has yet arisen, and, indeed, the station as at present equipped will be sufficient to meet all the demands on it for some time to come. Before long we shall probably have to increase the copper in some of our mains, and at an early date the question of extending the mains to streets not at present touched will have to be considered. Our policy in regard to extensions is to go anywhere within reasonable limits where a fair demand is likely to be forthcoming. I am glad to say the condition of the capital account is much more satisfactory than it was. During the past year we have issued £8,595 of share capital at a premium of 5s. a share. Practically the whole of the capital outlay during 1895 was met by the shares issued in that year, but we also placed during 1895 £7,500 of Four and a-Half per Cent. Debentures at 103. Our loans have been diminished from £10,000 to £3,100, and we have been able also to reduce the interest on them from 5 per cent. to 4 per cent. We have determined to exercise our option of paying off the Five per Cent. Debentures on July 1st next. The existing holders have agreed to accept £7,250 of Four per Cent. Debentures in exchange for their present holdings of Five per Cent. Debentures. Further applications for £400 of the new debentures have been received, and the balance we shall be able to place when the money is wanted. Turning to the revenue account, I may say that since January 1, 1895, the number of our customers has increased from 228 to 276, and the number of lamps on the system from the equivalent of 16,124 8 c.p. lamps to 18,900. The units consumed in 1895 were 162,428, compared with 107,218 in 1894, an increase of over 50 per cent.; the gross revenue has increased from £3,916 to £5,663, or by 44 per cent.; the expenditure has increased from £2,673 to £3,101, or by less than 17 per cent.; and the net revenue has increased from £1,243 to £2,562, or by nearly 106 per cent. These satisfactory results are due to the work done by our resident engineer at Hove, and to the care and attention of our secretary, to both of whom our thanks are due. Including the small balance brought into the accounts from last year, the amount on the credit side of the net revenue account is £2,577, which is reduced to £1,539 after charging against it the amount required for interest on the debentures and loans, and here I may remind you that we may hope in future to see a reduction in the proportionate amount required for interest on our debentures and loans. In dealing with the balance at the credit of net revenue account, which is sufficient to pay a dividend of 5 per cent. on the share capital, we have to give due consideration to the stability of the Company, and to provide for contingencies which may happen at any moment. In the first place we have to provide for the gradual liquidation of the preliminary expenses, and we have come to the conclusion that it is desirable to write off £134 under this head, leaving the amount to be dealt with in future £1,500. In all well-managed electric light companies it has become an axiom that a good reserve fund should be built up, and we have decided to recommend that £200 be credited to reserve out of last year's revenue, in addition to £460 realised by premiums on shares and debentures, making the total amount £660. With the remaining balance we recommend a dividend on the share capital at the rate of 4 per cent. per annum, carrying forward £152. In making these proposals we think it desirable to state that we hope to be able to recommend the payment of an interim dividend next autumn and in future years. In order to meet the wishes of our customers we have decided to adopt as from January 1st of this year the method obtaining in Brighton of charging by the "demand meter" system, which regulates the rebates or discounts allowed to customers in accordance with the actual consumption calculated on the maximum number of lamps in use at any one time. It is too soon yet to express any opinion as to the result of the change, but we trust it will lead to an increased consumption of current, so as to compensate the Company for any loss arising from the alteration. No doubt further modifications of the system of charging will have to be considered hereafter; but in the meanwhile the shareholders' interests will receive every consideration. The consumption of electricity is still increasing, and although not so rapidly as desired, it may be of interest for you to learn that the estimated net revenue for January and February of this year has amounted to £892, as compared with £714 in the same months of 1895. If this rate of increase can be maintained the accounts at the close of the current year should show satisfactory results. I think the figures I have placed before you are sufficient to show that the Company is likely to remain remunerative, and I may add that since the issue of this report we have received applications for shares to the amount of over £1,500, at a premium of 5s. per share. I now beg to move:—

"That the report of the Directors and the audited accounts and balance sheet to December 31, 1895, be and are hereby approved and adopted."

Col. H. WOOD, C.B. (Vice-Chairman), seconded the resolution, which was carried unanimously.

The CHAIRMAN then proposed:—

"That a dividend at the rate of 4 per cent. per annum for the year ended December 31, 1895, be declared and paid on April 15th next on the shares of this Company."

Mr. CARLETON F. TUFNELL seconded, and it was agreed to.

The CHAIRMAN moved the re-election of Mr. Tufnell as a Director, which was seconded by Col. WOOD, and carried.

The auditor (Mr. R. Payne, F.C.A.) having been reappointed, the proceedings terminated with a vote of thanks to the Chairman.

W. T. Henley's Telegraph Works Company (Limited).

The following Directors' report is to be presented at the 17th ordinary general meeting to be held at the Company's offices, 27, St. Martin's-lane, Cannon-street, E.C., on Friday next, the 13th instant, at 2 p.m.:—The accounts show a net profit of £21,823. 12s. 5d. After payment of debenture interest and income tax, and making an allowance for depreciation of plant, machinery, &c., there remains £17,342. 9s. 2d., to which must be added £1,600. 7s. 9d., the final dividend received from the International Cable Company (Limited), and £8,624. 9s. 3d. brought forward from last year, making a total of £27,557. 6s. 2d. Deducting from this £2,100, the interim dividend of 3 per cent. paid on the Ordinary shares on August 1st last, and £1,050, the half-year's dividend on the Preference shares paid in October, there remains a balance of £24,417. 6s. 2d. Of this sum the Directors have transferred £5,000 to reserve fund, and they propose the payment of the remaining half year's dividend on the Preference shares at the rate of 7 per cent. per annum, and a further dividend of 5 per cent., free of income tax, on the Ordinary shares (making a total distribution of 8 per cent. for the year, free of income tax, on the Ordinary shares). These payments absorb £11,050, leaving £13,367. 6s. 2d. to be carried forward. In the month of July last an issue of 3,000 Ordinary shares was made, and these were all subscribed for by the shareholders at par. The retiring Directors are Mr. Sydney Gedge, M.P., and Mr. Frederick Newton, who offer themselves for re-election, as do the auditors, Messrs. Ball, Baker, Deed Cornish and Co.

Oxford Electric Company (Limited).

The report of the Directors of this Company for the year ended December 31, 1895, to be submitted at the ordinary general meeting to-day (Friday) at 3.30 p.m., states that the revenue account shows a gross profit of £2,709. 8s. 3d. After providing for the full interest of 5 per cent. on the debenture issue and other interest, there remains a balance of £1,317. 9s. 4d., which, added to the amount brought forward from the previous year (£195. 4s. 8d.), leaves an available balance of £1,512. 14s. The Directors recommend that a dividend of 3½ per cent. be paid upon the Ordinary shares, which will absorb £1,152. 11s., leaving £360. 3s. to be carried forward.

The running of the plant during the year has given entire satisfaction, and current has been supplied to the public without the slightest interruption. Since the last report an equivalent of 3,797 8 c.p. lamps has been added to the system, and on December 31st there were 15,003 8 c.p. lamps connected. Fifteen colleges are now connected to the mains, and the Directors hope that the increase in the number of lights during 1896 will be equally satisfactory.

A new 150 H.P. engine and 100 unit dynamo of the same type as those already in use have been installed at the generating station, and various additions made to the machinery and plant during the year. In anticipation of an increase in the demand for current, the Directors are considering the expediency of enlarging the works at Osney and establishing additional sub-stations in various parts of the city. To provide for these extensions the Directors propose to issue 914 Ordinary shares of £5 each.

A new contract for the public lighting of the city has been entered into, the number of public lamps increased from 16 to 32, and the candle-power from 1,200 to 2,000 per lamp.

All the plant has been maintained in efficient order, and the expenditure for coal per unit of current delivered has been reduced to 0·55 of a penny.

The retiring Directors are Alderman Buckell, J.P., and L. A. Selby Bigge, Esq., M.A., who, being eligible, offer themselves for re-election, as does the auditor, Mr. W. S. Carver.

Birmingham Electric Supply Company (Limited).

The annual report of the Directors, to be submitted at the ordinary general meeting on Thursday next, the 12th inst., states that the net profit, including the balance of £1,001. 11s. 9d. brought forward, is £6,570. 11s. 8d. Out of this the Directors recommend the payment of a dividend of 4 per cent., absorbing £3,629. 9s. 9d., placing £1,920. 9s. 11d. to depreciation reserve fund, and £250 to the general reserve fund, carrying forward £770. 12s. On making this appropriation, the total reserves and undivided profits of the Company will amount to £9,463. 18s. 6d. There has been a steady increase in the Company's business during the past year, the total number of 16-c.p. lamps, or their equivalent, on order on December 31, 1894, being 12,138, and on the same date in 1895, 18,199. The number now stands at 19,401. The expenditure on capital account during the year amounted to £50,537. 2s. 1d. Considerable additions have been made to the plant and machinery at the Dale End Works, and included in the capital expenditure are the buildings and partial equipment of the Company's new stations at Edgbaston and Newhall-street, as also the underground mains that have been laid through a considerable portion of the Company's new Parliamentary areas. The Directors state that the two new stations are now in full working order. Although current was not available in the Edgbaston district till October last, the orders already received from that district are encouraging. The demand for current in the jewellers' district, both for lighting and power purposes, is also most satisfactory. In consequence of the reduced scale of prices adopted by the Board last year the number of customers has been considerably increased, and, although there was at first a slight falling off in the revenue, the result justifies the policy adopted. The increase during the year in the

Digitized by Google

use of motors has been considerable, and the Directors think that this will in time become an important addition to the Company's resources. In order to cope with the demand in the future, additional plant has been ordered for the Dale End station, and generating plant is also in hand for the Newhall-street depot. The registered capital of the Company has been increased from £100,000 to £200,000, and in October last 10,000 shares were issued at a premium of 5s. per share, and the premium of £2,500 had been applied to writing off preliminary expenses (£1,685. 2s. 4d.), writing off expenses incurred in the recent registration and issue of new capital (£154. 10s.), and the balance (£660. 7s. 8d.) towards the reduction of the charge on account of the Company's Provisional Orders. The retiring Directors are Messrs. H. Buckley and F. W. V. Mitchell, who offer themselves for re-election, as do the auditors, Messrs. Sharp, Parsons and Co.

NEW COMPANIES, STATUTORY RETURNS, &c.

COLONIAL LIGHTING SYNDICATE (LIMITED).—This Company has been registered at Edinburgh, with a capital of £2,000, in £50 shares, to contract for, and obtain rights and concessions for the supply of electric or other artificial light in any of the cities, towns or districts within any colony or dependency of Great Britain.

STANLEY MORRISON AND CO. (LIMITED).—This Company was registered on February 25th, with a nominal capital of £20,000, in £5 shares, to acquire and take over as a going concern the business carried on by Arthur Stanley Morrison at 24, Duke-street, Aldgate, London, and to carry on the business of manufacturers of and dealers in india-rubber, asbestos, gutta percha, electricians, telegraph and electrical engineers and contractors, submarine and other cable and telegraph instrument manufacturers, wire drawers, and contractors for the laying down and maintenance of submarine and land cables, telegraphs and telephones. The subscribers, with one share each, are: E. Burford Morrison, J. H. Morrison, C. E. Morrison, A. H. Morrison, S. H. Motion, F. B. Hooper and F. A. Scott. The first Directors are A. Stanley Morrison and Basil Gee.

DIRECT UNITED STATES CABLE COMPANY (LIMITED).—The annual return of this Company, made up to February 4th, has been filed. The nominal capital is £1,300,000, in £20 shares, and 60,710 of these have been taken up.

EASTERN TELEGRAPH COMPANY (LIMITED).—The annual return of this Company, made up to February 6th, has been filed. Out of a nominal capital of £4,700,000, 469,989 shares of £10 each have been subscribed for and allotted. The full amount has been called, and £4,699,890 has been received.

ELMORE'S AMERICAN AND CANADIAN PATENT COPPER DEPOSITING COMPANY (LIMITED).—The annual return of this Company, made up to January 13th, has been filed. The nominal capital is £200,000, divided into 65,000 Priority and 35,000 Deferred shares of £2 each; 44,788 of the former and all of the latter have been taken up, and the Deferred shares have been issued as fully paid. The full amount has been called on the Priority shares, and £86,044. 15s. has been paid.

ELMORE'S WIRE MANUFACTURING COMPANY (LIMITED).—The annual return of this Company, made up to January 14th, has been filed. The nominal capital is £300,020, divided into 133,500 Ordinary, 16,500 Preference and 10 Founders' shares of £2 each; 67,278 Ordinary, 15,000 Preference and 10 Founders' shares have been taken up, and the full amount has been called. £565 has been paid on 1,610 forfeited shares.

LINEFF ELECTRIC TRACTION AND LIGHTING SYNDICATE (LIMITED).—The annual return of this Company, made up to January 4th, has been filed. 11,431 shares have been taken up out of a capital of £15,000 in £1 shares, and of these 8,003 shares have been issued as fully paid. The full amount has been called and paid on the remaining 3,428 shares.

NEWCASTLE AND DISTRICT ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return of this Company, made up to February 25th, is filed. 5,000 shares have been taken up out of a capital of £100,000 in £10 shares, and £8 per share has been called.

ST. JAMES' AND PALL MALL ELECTRIC LIGHT COMPANY (LIMITED).—The annual return of this Company, made up to February 18th, is filed. The nominal capital is £200,000, divided into 19,980 Ordinary shares of £5 each, 20,000 Preference shares of similar value, and 100 Founders' shares of £1 each. All of these shares have been taken up, the full amount has been called, and £200,000 has been paid.

YORKSHIRE HOUSE-TO-HOUSE ELECTRICITY COMPANY (LIMITED).—The annual return of this Company, made up to February 18th, has been filed. The nominal capital is £100,000, divided into 19,900 Ordinary and 100 Founders' shares of £5 each. 18,848 Ordinary and 100 Founders' shares have been taken up, and the latter have been issued as fully paid. The full amount has been called on 10,000 Ordinary and £2 per share on 8,848 (payments in advance of calls).

CITY NOTES.

MEMORANDA.—Bank rate, 2 per cent. (Feb. 22, 1894). Price of silver, 1 3d. per oz. (March 5th). Consols (2½ per cent.) 109¼—109⅜ for money, 09¼—109⅜ for account; 2½ per cent. 105⅝—106 (March 5th). Stock xchange Settling Days: Consols, March 30th; Stock and Shares Connuation Days, March 10th and 25th; Ticket Days, March 11th and 26th; ay Days, March 12th and 27th; Mining Share Carry-over Days, March 9th nd 24th.

BELL'S ASBESTOS COMPANY (LIMITED).—The Directors of this Company have declared a dividend at the rate of 3 per cent. per annum, after acing £1,000 to reserve and carrying forward £2,200.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).—Notice is given that the transfer books of this Company will be closed from the 18th to the 24th inst. inclusive, preparatory to the payment of an interim dividend of 3s. per share (equal to 6 per cent. per annum), free of income tax, for the quarter ended December 31st last. The dividend is payable on the 25th inst.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended March 1, 1896, were £946, against £953 in the corresponding week of 1895, a decrease of £7. The total receipts for the half-year amount to £8,860, against £8,941 in the corresponding period of 1895, a decrease of £81.

COMMERCIAL CABLE COMPANY.—Mr. Clarence H. Mackay has been elected a director in place of the late Mr. J. W. Mackay, junr. The Directors have declared the usual quarterly dividend of 1¾ per cent., payable on April 1st next. The transfer books of the Company will be closed from the 20th inst. to April 2nd. The annual report of this Company states that the gross earnings amounted to $1,961,597; earnings from interest to $48,140, an increase of $3,939; net earnings to $1,215,308. an increase of $204,870; and the net surplus amounted to $515,308, an increase of $204,870.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The estimated amount of the traffic receipts of this Company for the month of February s £2,461.

EASTERN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of February amounted to £69,711, against £67,342 in the corresponding period last year.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of February, 1896, amounted to £48,233, and to £34,213 in the corresponding period of last year.

GREAT NORTHERN TELEGRAPH COMPANY.—The numbers are published of 100 1883 Debentures (Series B) of this Company, which have been drawn for payment on the 1st inst, at the offices of Messrs. C. J. Hambro and Son, 70, Old Broad-street, E.C. The traffic returns of this Company in February last were £22,000, and the total receipts for the period from the 1st January to 29th February, £44,400, against £41,000 and £44,400 in the corresponding months of 1894 and 1895 respectively.

ISLE OF MAN TRAMWAYS AND ELECTRIC POWER COMPANY (LIMITED).—The annual meeting of this Company was held at Douglas, on Friday last. The Chairman (Mr. A. Bruce), in moving the adoption of the report and accounts, referred to the satisfactory character of the balance-sheet and the gratifying results of the past year's working. The cost of working the horse section of their lines was 50 per cent. of the gross receipts, while the electrical section only cost 34 per cent. The report was then unanimously adopted, and the retiring Directors (Dr. Farrell and Mr. W. J. P. Pittar) were re-elected. An extraordinary general meeting of the shareholders was afterwards held, when resolutions approving the purchase of the Snaefell Mountain Electric Railway for £72,500, and increasing the capital of the Company to £175,000, were passed.

LIVERPOOL ELECTRIC SUPPLY COMPANY (LIMITED).—The ordinary general meeting of this Company was held on Friday last at the Exchange Station Salerooms, Liverpool. The Chairman (Mr. A. H. Holme) in moving the adoption of the report and accounts, said that the result of the year's working had justified the opinion expressed at the last meeting, that the Company was in a prosperous condition. They had largely increased their capital, and their number of lights. They had now nearly 40,000 lamps connected, an increase of 7,200 since January of last year. That would probably be their last meeting, as the Royal Assent would shortly be given to the Bill for the purchase of their undertaking by the Corporation, and within 42 days of that event the Corporation would pay them £8. 2s. per share. In reply to a shareholder, the Chairman said that the whole of the profit of the undertaking now went to the Corporation, less 6 per cent., which they were empowered to divide, and he concluded by moving that a dividend at this rate be declared for the half-year ended December 31st last, which was agreed to. Mr. A. H. Holme and Sir David Radcliffe, the retiring Directors, were re-elected.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended 1st inst. amounted to £1,056. The amount for the corresponding week last year was £934. Increase £122.

SANITAS COMPANY (LIMITED).—At a meeting held last week the Chairman, Mr. F. H. L. R. Moll, announced that the business done by the Company during 1895 had been very satisfactory. New articles had been introduced, and had met with an excellent reception from the trade and the public. He asked the shareholders to approve of a dividend equal, with a bonus of 9d. a share, to 13¾ per cent. per annum. Mr. C. T. Kingzett, Managing Director, explained to the meeting some details of the business, and pointed out that the increase in the demand for Sanitas preparations had necessitated considerable extension of plant at the works.

STOCK EXCHANGE NOTICE.—Application has been made to the Stock Exchange Committee to appoint a special settling day in, and to grant a quotation to, £200,000 Four per Cent. First Mortgage Debentures (Nos. 1 to 2,000) of John Fowler and Co., Leeds (Limited).

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended February 28th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,624.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the half-month ended February 29th are £2,681, against £1,947 in the corresponding period of 1895.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861—1878.

No. 930. [Vol. No. 20. XXXVII.] FRIDAY, MARCH 13, 1896. PRICE SIXPENCE.

NOTES.

In an article to be found in another column, Mr. W. C. Fisher deals a deadly blow at a very ancient electrical tradition. Time was when we were all taught to regard the Clark standard cell as an extremely delicate organism, to be handled with all the nervous solicitude due to an invalid. Mr. S. Skinner somewhat disturbed this belief in his Paper in the *Phil. Mag.* of September, 1894 (see *The Electrician*, September 28, 1894, p. 644), entitled "The Clark Cell When Producing a Current," where he showed, amongst other things, that using large cells with an exposed zinc area of about 95 sq. cm. and of a very low resistance, the electromotive equanimity of the standard was not upset when it was producing 0·01 ampere. And now Mr. Fisher's experience goes to prove that not only is a properly-made Clark cell, *i.e.*, one *not* made according to Board of Trade specification, none the worse for any amount of knocking about, but that short-circuiting—that once fatal disease—has lost its terrors. The curves of electromotive force given in Fig. 35 show in a striking manner the highly-beneficial effect of slight charging upon the rate of recovery of a severely short-circuited cell. It is also interesting to learn that a Clark cell, like many other organisms, is all the better for plenty of hard work. We think most of Mr. Fisher's results will be entirely new and decidedly useful to the majority of users of Clark cells.

Considerable interest will probably be evinced by electrical engineers, in the fact that the Brush Electrical Engineering Company have recently placed upon the market a vertical high-speed enclosed steam engine. The earlier type of Brush engine is well-known in this country, especially in provincial supply stations; but we may mention that it is neither an enclosed nor strictly a high-speed type, and in the majority of instances is rope-geared to the dynamos. The new engine, which it is intended to couple direct, exhibits therefore an important departure from the former practice of its makers. It is constructed to the designs of Mr. J. S. Raworth, by whom the earlier engine was also designed, and though built to run at high speeds it is equipped with Corliss valves and automatic expansion gear. Naturally enough, trip gear has not been introduced, the valves being actuated by positive motion. In this, however, the makers discover nothing but advantage, for the throttling of the steam at very low loads with such a valve gear is claimed to give higher economy than a sharper admission. We wish the newly-born engine a long and prosperous life, and await with interest the results of the trials which life inevitably has in store for it.

Whatever a practical steam engine builder has to say about the development of steam engines is entitled to respect, and on this account electrical engineers will welcome the opinions expressed by M. H. Lindley in his Paper on "The Development of Electric Lighting Engines," an abstract of which we print this week. The Paper bristles with practical information, chiefly in respect of the *minutiæ* of engine building; but we fail to discover in it any really philosophic or exhaustive account of the causes which have led to the development of that special type, the electric light engine. Mr. Lindley notes the adoption of moderate and high-speed engines in preference to the older type of mill engine, but he attributes it to such comparatively minor matters as the smaller cost of the former, and the universal adoption of white-metal bearings; and he scarcely so much as mentions the main reasons—viz., the avoidance of gearing while still retaining a high-speed dynamo, the higher steam economy per useful horse-power consequent on the better thermodynamic conditions, the use of single action, and the more compact and convenient sub-division of plant into units of manageable and economical power. There is unconscious humour, moreover, in the reason which Mr. Lindley has given for not dealing with the high-speed engine in detail—the electric light engine, *par excellence*, we had thought. "It is impossible to deal in any other than a general manner with this type," he says, "without simply describing A's or B's engine," which would no doubt be too good an advertisement for A or B.

Although it cannot be said, even by the most inveterate optimist, that the time devoted to the discussion of the Papers read by Messrs. Mavor and Bathurst before the Institution of Electrical Engineers in November, 1895, was time particularly well spent, so far as the advancement of the house-wiring question is concerned, three dreary evenings will not have been spent in vain if they serve to call attention to the character and method of discussion permitted. While the Papers themselves were, perhaps, not the best possible type of "curtain raiser" for a good session, both of them bristled with points of attack. All this,

Digitized by Google

however, was of no avail; the critics faced the points boldly, and—passed on. And the want of relevancy and practicality was not redeemed by any exhilarating display of wit; a portentous solemnity pervaded the proceedings worthy of the sad deliberations of a coroner's jury.

WHY was this so? Are our brilliant young consultants always so careful of each other's feelings? What is the nett result of the two Papers referred to, and the prolonged discussion to which they gave rise? We have a catalogue of the merits of conduit and concentric wiring, and of the demerits of wood casing: both lists, having been compiled by interested parties, require—editing, to say the least. Then we have placed on record in the discussion opinions as to the iniquities of insurance companies, bad habits of workmen, arrangements of working staff, &c., &c., all of which may be very interesting, but scarcely relevant to the question at issue. But granting that this may pass, why should three full evenings have been spent on the subject? It is clear that two things are necessary if the Institution is to do any real work at its meetings. Men not practically acquainted with the subject under discussion should be discouraged from speaking, and the time limit should be rigorously enforced. Given speakers who really have something pointed to say, they will not find much difficulty in saying it in ten minutes. Verbosity should be snuffed out by an automatic electric time bell, if the President finds it a task too delicate to undertake himself. At any rate he might extinguish irrelevancy.

THE holophane globe is certainly decidedly less cumbersome in appearance and less costly and more effective than the average scientific dodge for diffusing and distributing the light of the glow lamp or similar luminous source. At the same time, "Holophane" (Limited), the advertisements of which have during the past few days spread themselves over many columns of *The Times*, does not, it seems to us, possess a very substantial foundation. The manufacture and sale of holophane globes might, no doubt, prove a profitable adjunct to a well-established glass-globe business, but it is no more capable of supporting all by itself an entire company with a capital of £100,000 than a new form of thermometer would be. The vendor, not the inventor *bien-entendu*, is to be paid £80,000 for all the patents covering this little invention, excepting those relating to France and the United States. Considering the precarious nature of patent property, we doubt if any patent ever existed or ever will exist genuinely worth that sum *before* it has passed through the fire of the law courts right away up to the House of Lords, The easy assumption that the British public is going to absorb 663,400 holophane globes per annum is amusing. The holophane globe is undoubtedly a praiseworthy device; but, like the baby in "Midshipman Easy," it is "only a very small one," and we are sorry to see it made an excuse for extracting so much money from the investor.

THE Canadian Society of Civil Engineers have adopted a "code of engineering ethics"; whether they will observe the code is quite another matter, though doubtless it will find a place in every Canadian engineer's Molesworth. This engineering decalogue, or rather endecalogue, is drawn up in a style which has a faint flavour of Sandford and Merton, "Advertising with a view to attracting business should," we are gently told, "where resorted to, be as far as possible free from egotistic or self-laudatory references, and expressed in language not derogatory to the dignity of the profession"; a flower of rhetoric worthy of the Rev. Mr. BARLOW. Again, in the eleventh commandment it is ordained that "The Civil Engineer whose advice is sought in respect to the usefulness, practicability and cost of a work should, before expressing his opinion, obtain reliable information. . . . ." After which one almost expects to find the list of truisms winding up with the Quaker's warning "Friend, thou had best not eat peas with thy knife." No doubt Canadian civil engineering practices, like English electrical engineering practices, are in some need of regulation by ethical considerations, but a string of platitudes will not effect much in this direction. It is the unwritten law given by the example of the leaders of a profession that the minor professional lights fear to infringe.

WE publish this week an analytical table of the 1895 accounts of a number of electric supply undertakings doing business in London and in the provinces. This table will be added to as further accounts are forthcoming, and the table, with the additions, will be issued at regular intervals until the analysis is complete. When we first commenced this work, in 1892, the extent of the electric supply industry did not warrant more than one issue a year. To-day, with over one hundred concerns in operation, more frequent publication becomes imperative.

Cable Interruptions and Repairs:—

	Date of Interruption.	Date of Repair.
Zanzibar—Mombasa	Mar. 6, 1896	Mar. 9, 1896.
Puerto Plata—Martinique ...	Dec. 19, 1895	—

The Royal Society.—The Croonian lecture, "Observations upon Isolated Nerve: Electrical Changes a Measure of Physico-chemical Change," was delivered yesterday by Dr. A. D. Waller, F.R.S.

The Zipernowsky Transformer Patents in Italy.—The Siemens v. Zipernowsky transformer patent case was heard before the Court of Appeal at Florence last week. Judgment has been reserved.

New Anglo-German Cable.—The Silvertown Company has secured from the Post Office the contract for a new four-cored cable, some 230 miles in length, to be laid from the Norfolk coast to the Island of Borkum. The manufacture of the cable has already been commenced.

Electric Railway over the Rhine.—The construction of an electric railway between Düsseldorf and Crefeld, crossing the Rhine at Golzheim, has just been decided on. A company has been formed with a capital of £600,000. The line will be about 12 miles long, and the whole distance will be covered in 24 minutes. Trains to be run at intervals of 20 minutes.

Erratum.—In our description, last week, of the Bristol municipal electric supply station the horse-power of the "G G G S" Willans engines coupled to the 88-kilowatt alternators was stated in one place to be 100 H.P., and elsewhere in the article as 150 H.P. The former figure is obviously too small for the kilowattage, and we understand that the engines are rated by the builders at 150 H.P. each.

The Accumulator Industry in France.—The sole right to manufacture and sell the Muller and Tudor accumulators in France has just been acquired by the Société Industrielle des Moteurs Electriques à Vapeur (Système Heilmann). The

Digitized by Google

accumulators have hitherto been made by the Hagen Accumulator Company of Hagen, Westphalia, but will now also be manufactured at the Heilmann Works, in France.

Electric Rock Drills.—Electric rock drills are being adopted at the iron ore mines of the Hernadthal Hungarian Iron Industry Company at Krompact. Six drills are at first to be brought into use, and the generating plant, which is being put down by Messrs. Siemens and Halske, of Vienna, will comprise a semi-portable engine and boiler, and a 16-kilowatt continuous-current dynamo.

Manufacture of Bronzes and the Factory Act.—*Engineering* announces that the Secretary of State for the Home Department has issued an order under the Factory and Workshops Act, 1895, declaring that processes in the mixing and casting of brass, gun metal, bell metal, white metal, delta metal, and phosphor-bronze are dangerous or injurious to health, and therefore come under the provisions of the Act relating thereto.

Electric Emergency Lighting in Budapest Theatres.—To do away with the not very pleasant oil lamps which are now in use in theatres in case of emergency, the leading theatres of Budapest have obtained permission from the local authorities to displace the same by electric lamps. These lamps will be quite independent of the main lighting plant, and will it is hoped come into action when this latter breaks down.

Car Motor Ventilating Device.—To afford ventilation to entirely closed motors, the Philadelphia Electric Railway has adopted a very simple arrangement. From a ventilator on the car roof the cold air goes down through a pipe in the corner of the car, and feeds into the motor cases. From the cases it is discharged through one of the hot air escapes in the sides of the car. Which of the two holes is to be closed is determined by the direction the car moves.

City and Guilds Central Technical College.—We have received a copy of the Programme of the City and Guilds Central Technical College. Particulars are contained in it of the various departments of mathematics, engineering, physics and chemistry, and of the examinations, scholarships, &c., pertaining to the institution. The full course in electrical engineering extends over three years, and is under the direction of Prof. W. E. Ayrton.

The Telephone on the Continent.—Dalziel's agency states that arrangements are being completed for extending the existing through telephone service between Paris and Marseilles on to Cannes, Nice, and Monte Carlo, and that negotiations are pending between the London and Paris Postal Departments, so that the London and Paris telephone may be connected with the French inland trunk wires. It is also asserted that the French Government is seriously considering the practicability of telephone communication between Marseilles and Algiers.

The Pacific Cable.—A *Times* cablegram, dated Ottawa, March 5th, states that the Canadian Government have been informed that the conference between Mr. Chamberlain and the colonial representatives regarding the details of the Pacific cable scheme will take place at the Colonial Office the week after Easter. The Canadian delegates will be appointed in time to enable them to be present at the gathering. If the state of public business should enable him to leave Canada, Sir Mackenzie Bowell will be one of the delegates and Mr. Sandford Fleming the other.

Electric Traction in Rome.—The Rome Tramways Company is so satisfied with the successful result of the electric traction system started last September as regards economy of working and increase in receipts, that it has resolved to adopt electric traction on the whole of its network, and has presented a petition to this effect to the Municipality of Rome. At the same time a request has been made for permission to build five new lines to be worked electrically. The Naples Tramways Company has also petitioned the municipality of that town to grant a concession for the electric working of the entire tramway system, amounting in all to some 40 miles of double track. This is at present partially worked by horses and partially by steam.

Deodorising Gas Engine Exhaust.—A device for deodorising gas engine exhausts is described in the *Chemical Trades' Journal* as consisting of a box divided into two compartments by a perforated partition, on which bone black is spread in a moderately thick layer. The exhaust gases from the engine enter into the lower compartment at the extreme left, pass through the perforated dividing wall and superimposed layer of absorbent in the upper compartment, and thence escape into the open air through a pipe at the upper right-hand side. Thus the ammonia and fœtid hydrocarbon gases are absorbed by the bone black, and whatever liquid offensive particles may be in the products of combustion are retained by it mechanically. Water of condensation collecting in the lower compartment may be drained off through a drip pipe.

The Penetrating Qualities of the Arc Light.—In the first number of the *Photographische Rundschau* for 1896, Herr Schmidt, of Munich, describes some experiments he made about a year ago with regard to the penetrating quality of the arc light. He found that the light from an arc lamp passes more easily through certain substances than sunlight. A wooden board 2mm. thick was placed before a photographic plate, and an exposure of only 10sec. to 12sec. sufficed to attack the plate. Indiarubber, bone and ebonite proved less transparent with a thickness of 2mm., an exposure of half an hour was required to cause the same effect as through wood. Celluloid was found, however, nearly opaque. A 43-ampere continuous-current arc lamp was employed, the photographic plate being placed about 16in. from it.

Argon.—The recent discovery of argon in atmospheric air, by Lord Rayleigh and Prof. Ramsay, aroused such great interest that it has been resolved, says *Nature*, on the repeated request of the "general public" to prepare a volume containing an account of the methods of extracting the new gas from air, and of its properties, explaining, where necessary, in popular language, the basis of the reasoning employed in drawing conclusions relative to argon. But the whole history of the determination of the gases in air is so closely related to this recent discovery, that it would hardly have been possible to present the subject in its entirety without a preliminary sketch of the discoverers and their work. The little work, which has been written by Prof. Ramsay, and will be published by Messrs. Macmillan and Co., therefore treats of all the progress made in this branch of chemistry.

A Telephone System for Guernsey.—Two public meetings were held in Guernsey last week—on March 4th at St. Peter Port, and on March 5th at St. Sampson's—to consider the introduction of a telephone exchange system into the island. Both meetings were addressed by Mr. A. R. Bennett, who recommended that the work should be a popular one, undertaken either by the States of Guernsey or by a local co-operative company approved by the States. A representative of the National Telephone Company was present, and explained the terms on which his Company would open a Guernsey exchange; these were, however, rejected as too onerous. Ultimately it was unanimously resolved (1) that it is expedient to introduce a telephonic exchange system into Guernsey with the least possible delay, and (2) that a committee be appointed to consider the whole subject and to take the necessary steps to secure the establishment of an exchange by the States or by a co-operative company under the protection of the States. A committee consisting of 17 leading inhabitants, including several members of the Guernsey legislature, was elected, partly at the St. Peter-Port and partly at the St. Sampson's meeting. The committee held its first sitting on March 6th, and decided that the States should be recommended to apply immediately for a licence to telephone the island in terms of Clause 19 of the Treasury Minute of August 7, 1894. A telegram notifying the desire of Guernsey to manage its own telephone system, and the intention to apply for a licence was ordered to be despatched to the Postmaster-General.

Interior Lighting by Diffused Reflection.—We recently had an opportunity of inspecting the fine example of interior electric lighting on the diffused reflection system which has been carried out at the Union Bank of Australia in Cornhill by Messrs. Henry F. Joel and Co. to the designs of Mr. Goymour Cuthbert, A.R.I.B.A., and under the supervision of Mr. Hugh Erat Harrison. The magnificent main hall, which

Digitized by Google

is 72ft. long by 53ft. wide by 20ft. high, and is in the usual classical style affected by banks, is lighted by 91 groups of three 25 c.p. glow lamps suspended 6ft. from the ceiling in bronze dish-shaped fittings, made reflecting on the inside by a dull coating of tin. To those accustomed to the alternations of glare and gloom characteristic of so much of our modern public building lighting, the beautifully uniform illumination attained in the main hall of the bank leaves at first an impression upon one's mind, or rather upon one's retina, of uniform dullness. A few minutes, however, suffice to educate the eye up to the standard of this ideal mode of preventing injury to the human visual organs, and the sufficiency of the illumination is attested by the fact that the smallest print can be read with ease at the level of the bank desks. What special arrangements have been made for keeping the ceiling clean we do not know; the reflecting fittings are, however, arranged so that they can be easily dusted. The solid opaque bottoms of the basin pendants present a somewhat heavy and gloomy appearance, and we should have thought a little obscured glass might have been used with advantage here. All concerned, including the bank officials, are, however, to be congratulated on this bold and praiseworthy departure from the bad and beaten track of lighting by direct dazzlement.

Monopoly in Scientific Discoveries.—At the discussion on Mr. A. A. C. Swinton's Paper on "Röntgen's Photography of the Invisible" at the Society of Arts, last week, Prof. Dewar, chairman of the meeting, made the following remarks:—

". . . It was stimulating to the cultivation of real science to have a brilliant discovery like this (probably the most remarkable which had been made within the last half century; seeing that it had been rendered practically useful within less than three months of its publication), generally appreciated. They could see no end to the future work in abstract science which it opened up. It had, at the same time, stimulated a kind of criticism to which, perhaps, Mr. Swinton would be exposed, but which, in his opinion, ought not to be entertained. That was the view that a scientific discoverer had some kind of monopoly for an indefinite period of time in his discovery, and that his position was similar to that of an inventor. He should not have been surprised if this view, which had recently been promulgated in the scientific journals, had led to a kind of injunction being asked against their friend. He could not understand that position. There was no monopoly in science, and he felt convinced, though he had not the honour of knowing Prof. Röntgen himself, that he would not regard this widespread interest in his work as in any way detracting from his merits, but rather as adding new laurels to the value of the original investigation. He was sure Mr. Swinton would be the last man to do anything else than exhibit the marvellous fertility of Röntgen's discovery. To say that any investigator, if he locked the door of his laboratory and cultivated his own garden—as had been suggested—for a permissible period, could have done as much in three months as had been done in this case through publicity, would be simple nonsense. He could not but think that such ideas rather suggested that, instead of having regard to the real objects of science, there was too much consideration being given to the personality of the investigator. Now the merits of the investigator had often very little to do with the importance of the discovery. That was one reason why there could be no such thing as monopoly. Look at the antecedent work involved in Prof. Röntgen's discovery. On the one side you had the heredity from Faraday, who first suggested lines of force, to the great development made by Maxwell, to the work of Varley, and to that of Crookes. On the other hand, you had the work of Hertz, Lenard, and Röntgen. There were three Germans who had cultivated this field, and at least four Englishmen who had done admirable work. We, therefore, had our own share in the development of Röntgen's discovery, and every step had been necessary to the ultimate achievement. Of course, they always felt that somebody else might have discovered something, and that it was a pity he missed it; but really one man could not expect to monopolise everything, and there was plenty yet to be found out."

Röntgen Rays.—The *Comptes Rendus* for February 17th contains, as usual, numerous communications on the subject of Röntgen rays. M. R. Swyngedauw has a communication on the subject of the lowering of the sparking distance. Prof. Righi has a summary of the communication which appeared in full in *The Electrician* of last week. Prof. J. J. Borgman and M. L. Gerchun present, in an expanded form, the information contained in their telegram published in *The Electrician* of February 14th. MM. L. Benoist and D. Hurmuzescu present a Paper in which they state that they have verified that Röntgen rays are propagated in air according to the law of inverse squares. They also state that the Röntgen rays are heterogeneous. They base this statement on the fact that they find the coefficient of transmission for a 0·1mm. thickness of aluminium to be about 0·85, and they go on to say that such a value is absolutely incompatible with the very sensible transparency that Prof. Röntgen observed for a plate of aluminium 15mm. thick, if we assume that the coefficient is independent of the Crookes tube employed, and if it does not increase with the thickness traversed—that is to say, if X-rays are not subjected when passing through aluminium to selective absorption, which is a proof of heterogeneity. If the value 0·85 were constant, the total transparency of a sheet 15mm. thick would be represented by 26×10^{-12}. MM. Benoist and Hurmuzescu then carried on experiments with increasing thicknesses. They found that the coefficient increased from 0·85 for sheets not exceeding 0·6mm. thick, to 0·9 for sheets exceeding 1mm. They next employed different Crookes tubes under identical conditions, and found that the coefficient of transmission varied from 0·85 to 0·78. Another communication was made by MM. Auguste and Louis Lumière describing some experiments carried out by them with a view of ascertaining the amount of absorption which Röntgen rays undergo when passing through sensitive films. After ten minutes' exposure they found that photographic effects were produced through a packet of 250 sheets of gelatino-bromide-silver paper; they further found that 300 sheets of paper without the bromide emulsion exercised the same absorptive effect as 150 sheets of sensitised paper. They then experimented with photographic plates having different degrees of sensitiveness for white light in the ratio of extent of 1·8 to 30, and they found that within the limits of their experiments this ratio was exactly the same for Röntgen rays. Amongst the many communications to the Académie des Sciences there is one dated Liège, February 13, 1896, emanating from a M. de Heen, which commences as follows:—"In order to take date, I have the honour of informing you that according to my latest experiments the X-rays of Lenard and Röntgen do not emanate from the cathode, but from the anode." The last communication of any interest is one from M. G. H. Niewenglowski, in which he states that he has discovered that phosphorescent bodies have the same property of assisting the transmission of solar light as phosphorescent sulphide of zinc has in regard to Röntgen rays, a phenomenon which was recently pointed out by M. Charles Henry (see *The Electrician* of February 21st, p. 537).——MM. Able Buguet and Albert Gascard, in a note in the *Comptes Rendus* of February 21th, state that the natural diamond is far more transparent to X-rays than the imitation variety, and the same holds good for natural jet. In the same issue MM. Darieux and de Rochas briefly describe some experiments made with the eyes of freshly-killed pigs, which go to show that the media of the eye, so perfectly transparent to light, are but very slightly so to X-rays.

Contemporary Electrical Science.—In the *Physical Review* we find an advance paper by W. D. Bancroft upon the chemical potential of metals, *vulgo*, electromotive forces of cells. He finds that the potential does not depend upon the concentration of the solution, or upon the positive ion of the electrolyte. It may be described as a function of three things—the metal, the negative ion of the salt, and the solvent medium (usually water). Mercury and platinum acquire potentials of an opposite sign to those acquired by other metals with the same negative ion.—A very handy water battery is described in the same periodical by Austin and Thwing. Strips of copper and zinc are bent into a peculiar shape round a set of fixed pegs. A copper-zinc couple run downwards side by side, then bend away from each other, and then down again. This makes a kind of shoulder, and the lower ends can be immersed by springing a homœopathic vial on to the elastic couple and dipping the whole in water. A large number of such cells are placed side by side; the upper parts of the strips are bent again and soldered together, the junctions being mounted in a board and insulated with wax. One board can carry several hundred cells, and they may be filled by dipping the whole into a trough of water.—There is a paper on Sahulka's effect in the *Wiener Berichte*, 104, by F. Gold. The effect consists in a continuous current observed in an arc between iron and carbon poles fed with an alternating current. It flows from iron to carbon, and may be demonstrated by a magnetic needle. The arc has evidently less resistance in the iron-carbon direction than in the contrary. With a steady continuous current the arc is longer if the current flows from carbon to iron than if it flows from iron to carbon.

THE CROMPTON POTENTIOMETER: ITS USE AND CAPABILITIES.—V.*

BY W. C. FISHER, ASSOC.MEM.INST.C.E.

The Clark Standard Cell.

As in the potentiometer method all power, E.M.F., and current measurements are dependent upon the Clark cell as a standard of comparison, it is necessary that some description of its behaviour under *practical* everyday conditions and treatment should be given; for whilst much has been said and written with reference to it from a laboratory standpoint, the writer is unaware of its having been dealt with as a workshop standard, liable at all times to accidents, ill usage, and careless treatment, such as the endeavours, not by any means rare, of the sceptical "new assistant" to measure its voltage with a low-reading voltmeter, followed by his triumphant ejaculation —I knew it!—or, I thought so!—as the needle swings gracefully back to zero.

One is so accustomed to hear the Clark cell spoken of with bated breath as a kind of delicate organism, to be handled with the greatest care, never turned upside down or shaken, and duly provided with insulated terminals to prevent even such chance leakage as may take place through the fingers, that one hesitates to assert anything to the contrary; yet for all *practical* purposes and use all such precautions are unncessary and, more like its sister cell the secondary battery, the more it is

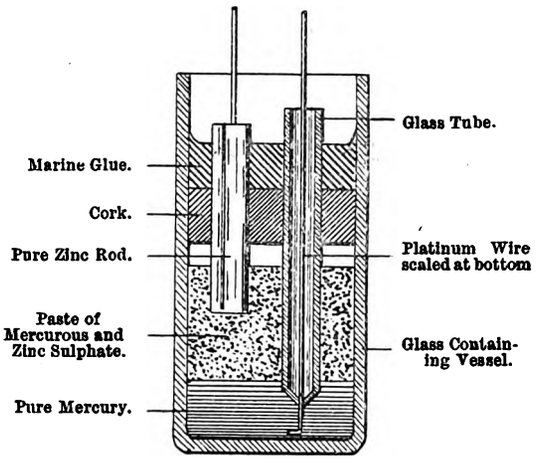

FIG. 26.

actually *worked* the more efficient and reliable it becomes. To many this may appear a strange statement, but it has been proved repeatedly—to those who have met it with incredulity—that the terminals of a properly-constructed Clark cell may be coupled together with an inch or two of thick copper wire, and yet in a very short time the cell returns to its full value, such time being entirely dependent upon the duration of such treatment. This recovery may also be accelerated to such an extent that a cell so coupled up for 24 hours, and which would normally require 36 hours to recover completely, may be brought up to value sufficiently accurate for all practical purposes in an hour or two, or even less; that such is the case will presently be shown. Before doing so, however, a brief description of the forms in use might be of interest to some.

The Board of Trade, in adopting the Clark cell as a standard of E.M.F., gave it the value of 1·434 Board of Trade volts, at 15°C., and in their specification of such a cell require it to be made up in the form shown by Fig. 26, and accentuate certain points in manufacture to which attention should be paid. The cell is sufficiently explained in the figure, yet constructed in this manner, and carrying out strictly the instructions given in the specification, the results attained are somewhat disappointing, and as such disappointments have been heard of from more than one quarter, it would seem as if there were something wrong somewhere. Fig. 27 gives a curve of the variation in value of 12 cells taken at random out of a batch of about 50 made up to the Board of Trade specification. The full line curve representing the values some 24 hours after construction, the dotted line being the values six days later at a different temperature, the extreme variation, as will be seen, being in each case nearly 1 per cent. After repeated trials with varying and uncertain success all attempts at manufacture were given up, and since that date the writer's experience has been entirely with cells made by Messrs. Muirhead, the original makers of this standard. Moreover, owing to the quantity of loose mercury introduced in the official cell, it is not advisable naturally to unduly shake or invert it in any way on account

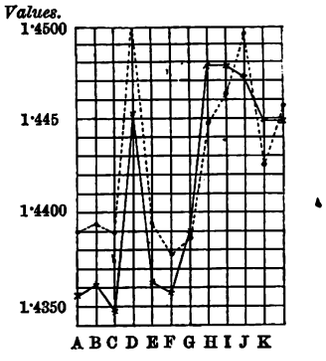

FIG. 27.

of the disarrangement so caused, and this is a distinct disadvantage, for such standards to be of any use must be capable of standing a certain amount of rough usage; they cannot always be carried in one's waistcoat pocket. After repeated trials it is unquestionable that Messrs. Muirhead's improved cell, shown in Fig. 28 (which is self-explanatory), where you have but a globule of mercury retained by surface tension and the surrounding paste within the spiral of platinum wire shown, will stand without injury the most brutal treatment. Whether submitted to all the tenderness usually displayed by the average railway employé, or sent by parcel

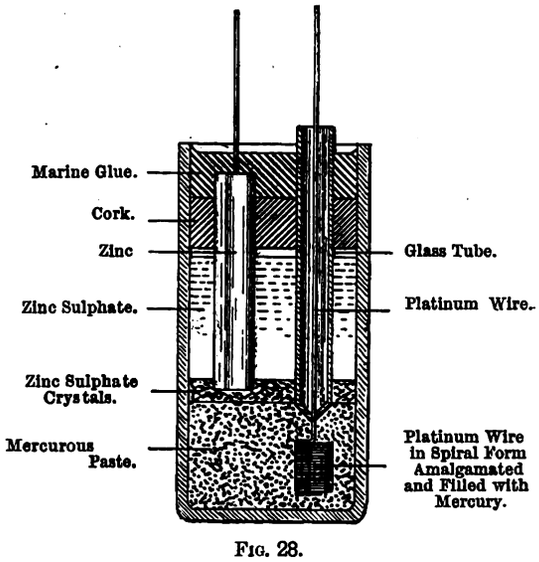

FIG. 28.

post to places as distant as the Transvaal and Australia, the writer has never known one case in which any cell failed. Twice or thrice cells have been returned on account of the mercury in the thermometer having lodged at the top—evidence of a more than usually severe bump. This put right the cells went their third journey uninjured. It might be interesting to mention that in the case of the cells sent to the Transvaal, four cells were sent to Pretoria by parcel post, with instructions to test immediately on arrival. This, by the kindness of the recipient, was done, with the result that the variation between three of the cells was inappreciable, the fourth was out considerably but showed signs of rapid recovery with the

Digitized by Google

result that within 48 hours of their arrival little or no difference in all four cells was observable.

The writer should mention that Fig. 28 represents the cell as first constructed by Messrs. Muirhead, the form is now slightly altered, the platinum spiral being flattened and placed at right angles with the glass tube, in which it is sealed at the top as well as the bottom.

With reference to variation in value of Muirhead-Clark cells, Fig. 29 gives a series of curves showing the variation in a batch of 12 cells delivered. The curves are of interest, especially when compared with those of the official cells shown in Fig. 27, and which are to the same scale, each horizontal line indicating $\frac{1}{1000}$th of a volt.

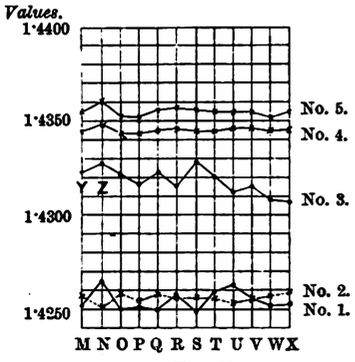

FIG. 29.

Curve No. 1, shown in Fig. 29, gives the variation immediately on delivery, without temperature corrections, showing a maximum variation of $\frac{1·5}{1000}$ths of a volt, and a mean variation of about $\frac{0·7}{10000}$ths. Curve No. 2 represents the value of the same cells after 24 hours' rest, the maximum variation being about $\frac{8}{10000}$ths, and a mean variation of very much less, especially if the chief delinquent N be omitted. Curve No. 3 shows the values of the same cells—with the exception of M, N, which were sold, and for which two others Y, Z were substituted—in the midst of the experiments about to be described. Curve No. 4 was taken six days after the conclusion of all experiments and Curve No. 5 14 days after same. In this last case there were several slight discrepancies due to a different and less steady galvanometer being

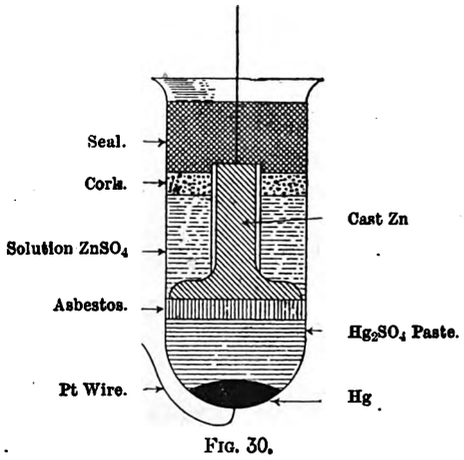

FIG. 30.

employed, which, if corrected, would tend to render the curve more even and in character with No. 4.

From these curves it will be seen that under exceptionally trying circumstances the maximum variation only amounted to $\frac{1}{500}$th volt. Under ordinary conditions the curves speak for themselves, and it is a matter of conjecture as to what the small variation shown is due, for whilst Messrs. Muirhead assure the writers that absolute cleanliness and purity is observed as specified for the official cell, there is no particular care and dexterity required in manufacture, and it is very seldom that they have cells which vary too much above or below normal value.

Prof. Carhart in America recently devised an improved cell, shown and explained by Fig. 30, the English cells having in his opinion three defects. The zinc is in solution of varying density, and therefore attacked at the higher levels. To prevent this he protects the zinc by a glass sleeve after it leaves the lower stratum of saturated solution. In the second place the cell is not portable, and this he overcomes by confining the mercury by ramming the paste upon it by means of a flat zinc with a piece of asbestos interpolated. And thirdly, he objects to the use of cork. An account of the behaviour of this cell would be interesting; also whether Prof. Carhart has found any unsteadiness through the use of the asbestos, which he prefers to cork, as from the writer's experience of it in another direction, he should hesitate about its introduction into a standard cell of the Clark type even after severe chemical treatment.

The specific gravity difficulty mentioned by Prof. Carhart would be simply got over in the cell shown in Fig. 31, which was devised by the writer to reduce for particular reasons the internal resistance of the standard. In it the old grid form zinc of the gravity Daniel cell is taken as a model in combination with Muirhead's spiral of platinum. In it the question of variation of specific gravity is overcome by want of depth, but the expense in manufacture, especially if the platinum spiral be

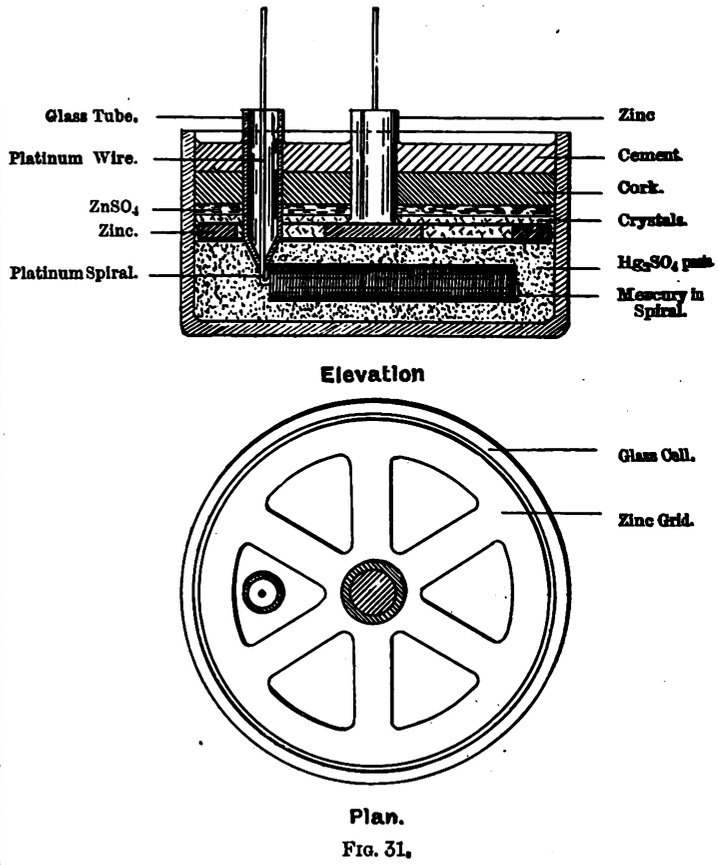

FIG. 31.

made of any size, is against its universal adoption. It is possible this might be overcome by the use of a compound wire, say platinum with an iron core, but experiments have not been made in this direction.

Since this article was written, Dr. Hibbert, of the Polytechnic, has brought before the writer and submitted for test nine standard cells of *one* volt. So far as preliminary tests go they promise well. Their agreement with each other is remarkably close, their temperature coefficient is negligible, their internal resistance low, and their recovery to full value after charge and discharge is accomplished in very much less time than that taken by the Clark standard. If successful in passing the higher temperature and time tests they will certainly supply a want as the missing full volt standard.

When we view the behaviour of the Clark cell under any but general electrical treatment the results are certainly astonishing, and effectually destroy the ancient traditions already mentioned. The marvellously quick recuperative power of the Clark cell was first brought to the writer's knowledge six years ago, when, owing to the accidental twisting

Digitized by Google

together of the wrong pair of leads, a cell was short-circuited, and in accordance with ancient tradition, believed to be spoilt accordingly. A very few minutes after, through habit in the use of switches, it was brought into circuit and found to be none the worse. Somewhat in doubt, it was checked and found to be but imperceptibly out. To avoid any mistake, it was deliberately short-circuited, with the same result: a steady creep up to full value. Since that time short circuits have been taken no notice of, the cell, after several trials, being relied upon to come up to value in from 10min. to 15min., and there being always one cell in reserve, this time was a matter of no moment.

Shortly after this it was noticed that recovery could be accelerated by a slight charging of the exhausted cell, but no definite experiments were made until recently, when, at the

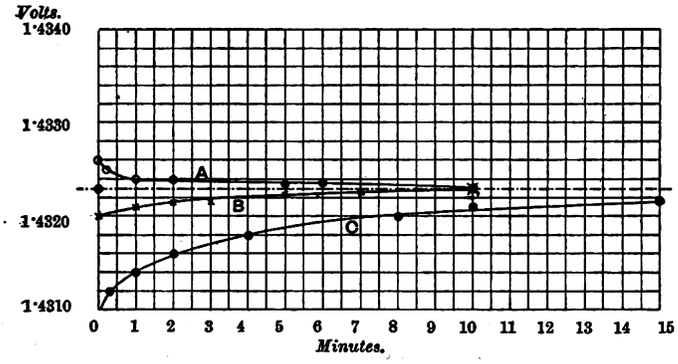

FIG. 32

suggestion of Mr. A. P. Trotter, actual recovery curves were taken under varying circumstances, which effectually placed beyond dispute the facts the writer has already mentioned. The experiments were made with the cells, the variation curves of which are shown in Fig. 29, and some of the results obtained are herewith given as briefly as possible

I. Fig. 32 gives three recovery curves corresponding to the following treatment of the same cell. (A). After a 1min. charge at an E.M.F. $\frac{1}{100}$th of a volt in excess of the cell value, the cell volts rose in value from 1·4323 to 1·4326 volts, or $\frac{3}{10000}$ths of a volt, and gradually fell, reaching the original value in 10min. or so. (B). After a 1min. discharge due to a want of balance of $\frac{1}{100}$th volt, the value of the cell fell to

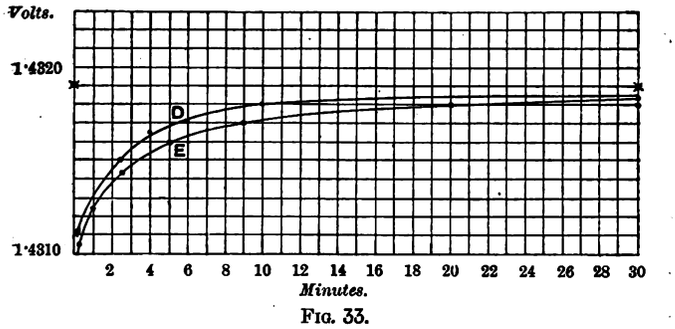

FIG. 33.

1·432, the recovery with time subsequently being gradual throughout until full value was again reached in 10min. (C). The cell was connected up to a low-reading voltmeter of about 500 ohms resistance for a period of 1min.; its value fell from 1·4323 to below 1·431. The early part of the recovery was rapid, afterwards becoming more slow, full recovery taking place in 30min. from disconnection of voltmeter. The last readings are not shown upon the curve.

II. Fig. 33, D. After 30sec. short circuit through 2in. of No. 18 copper wire, another cell fell in value from 1·4319 volts to below 1·431, and gradually recovered in 30min.; before it had fully recovered, it was again treated in similar manner when E indicates its recovery, at the same time showing the accumulative error or lag. In the case of tests F, G, H, I, and J of a similar nature, and curves of which are not given, this repeated lag by neglected full recovery was more pronounced and regular.

III. Fig. 34, K. A 5sec. discharge through wire above mentioned of another cell was the cause of a fall in value from 1·4343 to 1·434 with gradual recovery as shown, a second similar treatment followed by one of 30sec. duration was productive of curves L and M, which were again repeated by repetitions of 5sec. and 30sec. discharges, K—apparently the maiden effort—not being again repeated. N is the recovery curve common to four successive discharges of 30sec. duration of the same cell, but at a different temperature, full recovery being allowed between each discharge.

IV. Fig. 35, O. A cell had its terminals connected with a few inches of wire (No. 20) for 20 hours, in which time it fell from 1·4331 to 0·17 volts; its recovery was very slow at first, and continued so, until it got to 0·5 volt—the average rate being 0·03 volt per hour. After this it rapidly rose at an average rate of 0·1 volt per hour, until approximating full value was

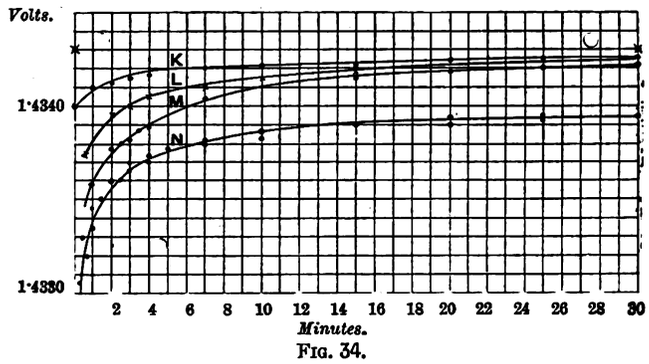

FIG. 34.

reached, the whole occupying about 24 hours; and it should be mentioned that 48 hours after this severe test, the difference between this cell and its partner in the case was $\frac{7}{10000}$ths of a volt, as compared with $\frac{1}{10000}$th before the test, and to which value it again gradually settled down after 48 hours rest. In this curve the time is indicated in hours at the top.

P. Another cell treated in similar manner for 20 hours had a constant potential of 1·4 volts placed on its terminals, and it was so charged, with the result that, as shown by the curve,

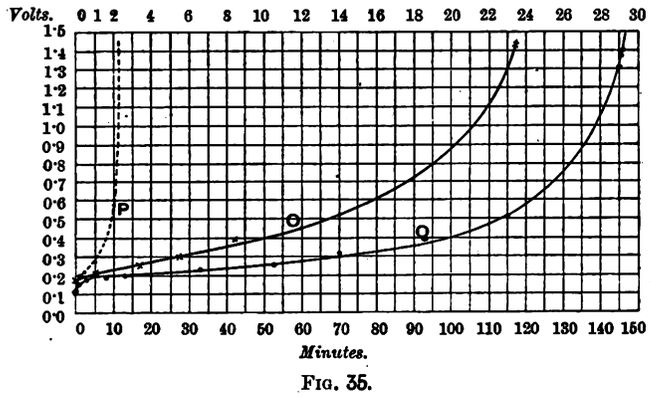

FIG. 35.

it reached its full value in 2½ hours. This curve is shown enlarged by Q, the time being indicated by minutes at the foot. The value of this cell, compared with its companion before test, was 1·4327, and 24 hours after commencement of recovery it stood at 1·4325 at same temperature, a difference of $\frac{1}{5000}$th of a volt.

Ordinarily a cell takes 8½ to 9 hours to rise from 0·5 of a volt to full value; charged at 1·4 volts, the time so occupied is less than 30min.

The following short experiments are also interesting:—

1st cell, after 5sec. short circuit, fell from 1·4319 to 1·4311;
" after 10sec. $\frac{1}{20}$th volt excess charge, its value rose to 1·4319 again.

2nd cell, after 30sec. short circuit, fell from 1·4319 to 1·4308;
" after 20sec. $\frac{1}{20}$th volt excess charge, it had risen to 1·4319 again.

Digitized by Google

These are but a few of the results obtained from a large number of tests made, and have been a source of surprise to many who have been accustomed to treat their cells with all due traditional respect. Apply rough theory to the subject, the only conclusion one can come to is that the instant the cell commences to do work the internal resistance goes up enormously, so automatically cutting off the possibility of great injury. Ordinarily the cells have an internal resistance of about 750 ohms or less when in a healthy condition. This runs up very much after discharge; the full extent is not known, and it is difficult to ascertain, the cell commencing recovery at once, giving no time for test. Such tests as have been made prove the resistance to be at least double, even after a comparatively slight discharge, and with no tendency to materially increase after a heavy one. Apparently the internal effect is of a skin or filmy nature, which the vitality of the preponderating mass of material speedily overcomes. It is possible that the following experiment, shown the writer by Mr. Higgins, the engineer of the Exchange Telegraph Company, about 1884-5, may throw some light on the subject. If a shallow vessel of about 2in. or 3in. diameter be taken, and mercury placed therein, and a solution of sulphate of zinc be added, an attempt to produce a standard cell electrolytically is productive of great commotion upon the surface of the mercury, films of sulphates form only to break up, showing the metallic gleam beneath, and fly hither and thither in a curious and interesting manner. Whether anything akin to this takes place on a small scale when the ordinary cell is recuperating, and whether, as it would seem, this is accelerated by a slight charge, it would be of interest to know for certain.

As showing the effect of idleness and work upon such cells, the following may be of interest: one of the successful cells made to the Board of Trade specification, and which had been in enforced idleness for several years, was found upon test to have an internal resistance of *10,400* ohms; a preliminary short circuit and recovery reduced this to 7,500 ohms, a 30 seconds discharge *reduced* this to 1,300 ohms, which rose with recovery of cell to 6,100 ohms; a second discharge of 60 seconds duration again *reduced* the internal resistance to 2,400 ohms, which again rose with recovery to 4,000 ohms. It was still further reduced by other tests, but left to itself for a few days its internal resistance gradually rose, 14 days after its value being 8,600 ohms. The recovery curves of this cell were at first most erratic, but gradually assumed the characteristic recovery curve common to the others; its value also improved, being low before tests it gradually rose, and even after the 14 days rest it was 50 per cent. nearer the value of the standard.

The writer has to thank Mr. Henry Lea, C.E., for permission to publish the following extract in corroboration of the above. Mr. Lea, as is well known, is the electrical inspector to the city of Birmingham:—

"Two of the cells (I, J) have been in regular use ever since the test room was started (five years). Occasionally they have been deliberately short-circuited by a No. 16 copper wire. K and L are two months old. No. 456 (an occasional cell) is six months old, and used seldom. The Fitzgerald is new every time it is made up. A recent comparison gives the following result at 15°C.:—

I = 1·4341
J = 1·4339
K = 1·4341
L = 1·4340
456 = 1·4286
Fitzgerald ½hour old = 1·4340

"Comparisons of this kind have often been made here, and the results are generally the same."

In the above we have evidence again of two cells in constant use, or, as some would say, abuse, for five years, yet differing between each other but $\frac{1}{5000}$th, and from the standard but $\frac{1}{10000}$th of a volt. On the other hand, we have one idle for six months only, and differing from the standard by $\frac{1}{200}$th of a volt.

In further proof the following is given also as showing that the life of cells so treated is not shortened. The figures are those of two cells—K and L—made by Prof. Fleming in 1886 or 1887.

Nov. 1886-7	K = 1·4356	L = 1·4358	difference	0·0002
Jan. 1888	K = 1·4357	L = 1·4359	,,	0·0002
Feb. 1891	K = 1·4359	L = 1·4361	,,	0·0002
Jan. 1895	K = 1·43837	L = 1·43874	,,	0·00037
Jan. 1896	K = 1·4322	L = 1·4326	,,	0·0004
Feb. 1896	K = 1·4363	L = 1·43668	,,	0·00038

Prior to 1894 these two cells had been in constant daily use. Owing to other arrangements they have since been very seldom used, with the result that the discrepancy is increasing, whilst the internal resistance of K, which is least used, has gone up to 8,000 ohms.

It is possible that the potentiometer method of measurement itself, in producing constant minute charge and discharge, due to small differences of potential caused by depression of the key at points out of balance, is productive of good. But the writer must acknowledge to a feeling of doubt at one time as to whether one really had a true value or not, but by means of an increased sensibility in the galvanometer he has satisfied himself that, with ordinary care, it is quite possible to balance well within $\frac{1}{10000}$th of the value of the cell, for one automatically corrects any discrepancy produced by want of balance by instinctively shifting the point of contact to want of balance upon the other side, these very acts of see-saw eliminating the effects of each other, added to which is the fact that there should always be a second cell to fall back upon as a check.

THEORY AND CALCULATIONS OF ASYNCHRONOUS ALTERNATE CURRENT MOTORS.

BY A. HEYLAND (BUDAPEST).

(*Continued from page 581*).

III.—B. *Various Loads.*

After having investigated the conditions of *normal load*, it becomes of interest to ascertain how these conditions change with varying loads; in particular to inquire the status at *no load* and at *excess of load*. We have further to determine the *maximum excess of load* which the motor can bear.

The diagram Fig. 6B clearly depicts these relations if we regard the coefficient τ as constant, approximately equal to that τ which is valid for normal load. In doing so, we shall not introduce an error of any great consequence; for the permeability of the iron, and hence also τ, will vary little, as it is customary to work with low saturation. In perforated armatures, in which the stray lines are confined to the iron, the saturation may indeed attain higher values, and τ will decrease with rising current intensity. In the grooved armature, on the other hand, the lines experience their chief resistance in the air gaps between the teeth; the saturation will rise with the load and the permeability will diminish, but τ will be little affected. In any case, higher saturation will exercise a rather favourable influence; for at higher loads there will be less leakage than we should have for a constant τ. The actual conditions will hence be more favourable than those we have assumed for the calculations. It results that the hypothesis of a constant τ is justified.

(1) *Relations between the work expended* A_1, *the current intensities* I_1 *and* I_2, *and the power factor* $\cos\phi$, *as dependent on the constant quantity* τ, *and the maximum power factor f.*—Any variation in the load expresses itself, in Fig. 6B, by the movement of the point $C' C'' \ldots C^n$ (Fig. 10) on the circular path marked. In this figure—

$A C^n$ represents the primary current I_1;
$C^n C$,, ,, secondary current I_2;
$A C$,, ,, magnetising current I;
angle $C^n A B = \phi$, the difference of phase between K, the primary P.D., and the primary current I_1;
$\cos C^n A B = \cos\phi$, the power factor;
$K I_1 \cos\phi$, the primary work expended A_1;
$A A^n$, the projection of $A C^n$ on $A B$;

Digitized by Google

$A\,A^n = I_1 \cos\phi$, the work primarily expended, measured in the scale $\frac{1}{K}$.

$I \cos\phi$ may also be represented by perpendicular $C^n c^n$ let fall from C^n on $A\,O_c$, so that also

$C^n c^n = I_1 \cos\phi$, the work primarily expended, measured in the scale $\frac{1}{K}$.

All these quantities vary when the point C^n describes its circle, and we can refer the variations to the angle $C^n\,O_c\,A$,

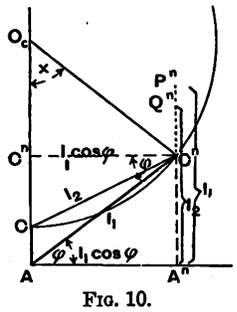

Fig. 10.

which we will call x. We can express all the terms introduced in the angle x, the radius $O_c C^n$, and the line $A\,O_c$. These two latter lines are connected by the equation (*see* Fig. 7)

$$\frac{O_c C^n}{A\,O_c} = \frac{O_c C}{A\,O_c} = f, \text{ the maximum power factor.}$$

To express the quantities as explained, we take the radius $=1$, and therefore $A\,O_c = \frac{1}{f}$, when we arrive at the following values:—

$$I_1 \cos\phi = C^n c^n = O_c C^n \sin x = \sin x, \quad . \quad . \quad (31)$$

$$I_1 = \sqrt{A\,O_c{}^2 + O_c C^{n2} - 2\,A\,O_c \cdot O_c C^n \cos x}$$

$$= \sqrt{1 + \frac{1}{f^2} - \frac{2}{f}\cos x}, \quad . \quad . \quad . \quad . \quad (32)$$

for which we may write:

$$\sqrt{1 + \frac{1}{f^2} - \frac{2}{f} + \frac{2}{f}(1 - \cos x)} = \sqrt{\left(\frac{1-f}{f}\right)^2 + \frac{2}{f}(1 - \cos x)}.$$

For higher loads and increasing x, the first term vanishes, and we obtain approximately

$$I_1 \equiv \sqrt{\frac{2}{f}(1 - \cos x)} = \frac{2 \sin \frac{x}{2}}{\sqrt{f}}. \quad . \quad . \quad . \quad (32A)$$

Further,

$$I_2 = C^n C = 2\,C\,O_c \sin\frac{x}{2} = 2 \sin\frac{x}{2}, \quad . \quad . \quad (33)$$

from which results that for higher loads the ratio

$$\frac{I_2}{I_1} \text{ tends to become a constant} \equiv \sqrt{f}. \quad . \quad (34)$$

Finally,

$$\cos\phi = \frac{I_1 \cos\phi}{I_1} = \frac{\sin x}{\sqrt{1 + \frac{1}{f^2} - \frac{2}{f}\cos x}}, \quad . \quad . \quad (35)$$

which, for higher loads, approximates

$$\cos\phi \equiv \frac{\sin x \sqrt{f}}{2 \sin\frac{x}{2}} \equiv \cos\frac{x}{2}\sqrt{f}. \quad . \quad . \quad . \quad . \quad (35A)$$

From I_1 and I_2 we derive $d a_1$ and $d a_2$ respectively, equal $I_1{}^2 W_1$ and $I_2{}^2 W_2$, *i.e.*,

$$d a_1 = \frac{2(1 - \cos x)}{f} W_1. \quad . \quad . \quad . \quad . \quad (32B)$$

$$d a_2 = 2(1 - \cos x) W_2. \quad . \quad . \quad . \quad (33A)$$

As the projection of $A\,C^n$ upon the base is a measure for the work expended, the system of polar co-ordinates can easily be transformed into one of rectangular co-ordinates. This is done in Fig. 10 by dropping a perpendicular from C^n, and cutting off

$$A^n P^n = A\,C^n = I_1$$

$$A^n Q^n = C^n C = I_2.$$

If we carry this out for various loads, the points P^n and Q^n will describe curves whose abscissæ represent the work expended, and whose ordinates the corresponding current intensities. By dividing the abscissæ by the ordinates of I_1, we obtain a third curve illustrating how the power factor $\cos\phi$ depends upon A_1,

$$\cos\phi = \frac{I_1 \cdot \cos\phi}{I_1}.$$

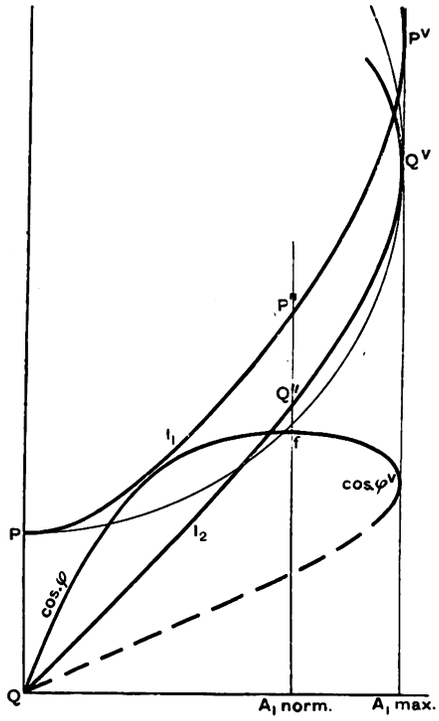

Fig. 11A.—Curves for I_1, I_2 and $\cos\phi$, depending on the work absorbed when $\cos(\phi_{\min.}) = f = 0{\cdot}7$.

In Figs. 11A, 11B, 11C, these three curves have been plotted in the manner explained for the three cases, maximum power factor $f = 0{\cdot}7$, $0{\cdot}8$, $0{\cdot}9$.

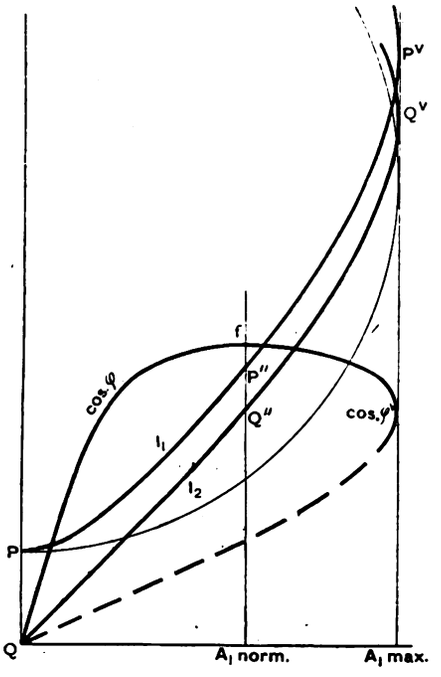

Fig. 11B.—The same for $f = 0{\cdot}8$.

We recognise the characteristic shapes with which practical load tests have made us familiar. The trend of the curves is determined by that f which stands for the case of normal load. We shall best understand the interdependence of these

Digitized by Google

brittle materials, and rely for strength upon their great crushing resistance and high elasticity rather than upon toughness; but when well made and properly set at a moderate depth below the ground, neither material gives trouble from fracture due to vibration or crushing. Chemically speaking, stoneware is superior to cast-iron, since in the finished form as used for conduits stoneware is neither chemically acted upon nor physically disintegrated by the fluids which occur in town sub-soils. Clays have little action on cast-iron, but gravelly and porous soils and the sub-soils of streets carrying sewers and gas mains are decidedly corrosive of pipes of this material. The higher degree of smoothness in stoneware surfaces, as compared with cast-iron, or the extra cost of finishing off the interior and ends of a cast-iron pipe, will give the advantage to the former material in respect of the absence of abrading action on a cable. High insulating power is not a quality essential to a conduit, neither in the streets nor within houses; but the imperfect conductivity of stoneware, by comparison with the high conductivity of cast iron, constitutes a certain advantage in its use in most cases. The actual relative costs of stoneware and cast-iron conduits will not be an easy matter to settle in general terms, so much depending on the local facilities in obtaining the materials. In general, however, a stoneware

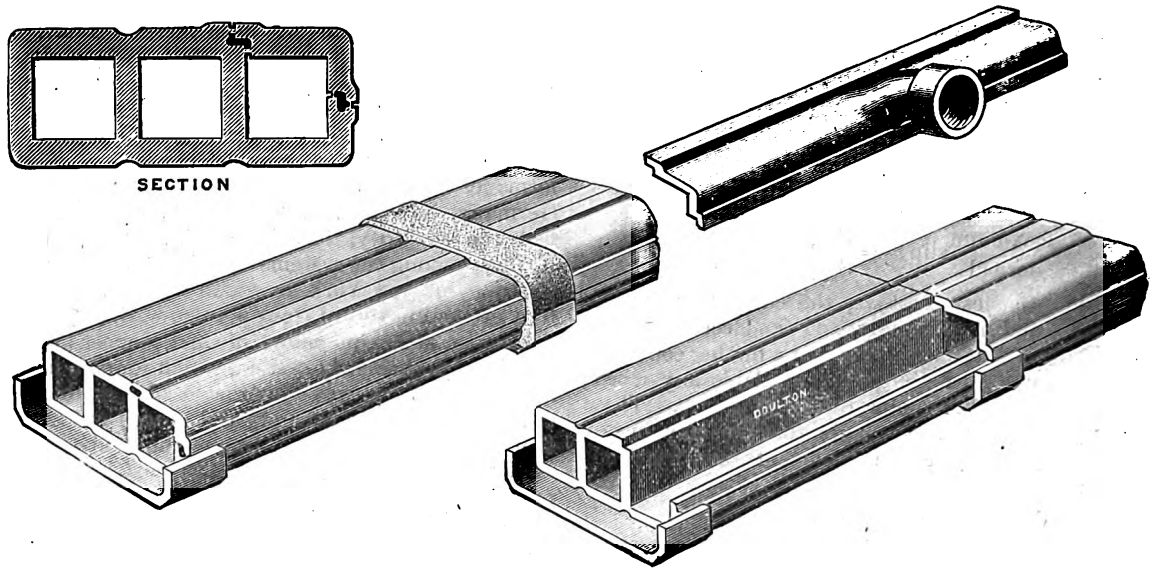

FIG. 1.—Details of Doulton Stoneware Conduit, Type "B 1," as used at Portsmouth.

Digitized by Google

conduit for a given set of cables, and for equal strength, will cost less and weigh less than a cast-iron pipe conduit. The following table gives the prices of cast-iron pipes and of various forms of stoneware conduit, as manufactured by Messrs. Doulton and Co., for electric supply mains :—

Type of conduit.	Price per yard.
	s. d.
Cast-iron socket pipe, in 9ft. lengths, 4in. diameter, 51lb. per yard	4 6
Ditto, in 9ft. lengths, 6in. diameter, 88lb. per yard	7 6
Glazed stoneware circular pipe, spigot and socket joint, 4in. diameter	2 0
Ditto, 6in. diameter	3 0
Doulton type "B 1" stoneware conduit (Fig. 1), as used at Portsmouth, with 2½in. by 2½in. ducts, including jointing chairs	2 6
Ditto, 4in. by 4in. ducts	5 4
Ditto, type "B 2" (Fig. 2), 2½in. by 2½in. ducts	2 6
Ditto, type "C" (Fig. 3), 6in. by 2¾in.	1 9

It must be borne in mind that the foregoing statements of the prices of various kinds of conduit do not necessarily give the relative costs of actually installing them, since so much will depend on the nature of the ground and of the route and the price of labour and extras. For instance, where the conduit has to pass under a vehicular way carrying heavy traffic, it will generally be necessary to place a stoneware conduit at a greater depth than one of cast iron, or to embed it securely in concrete; but even this consideration will be affected by the nature of the road, surface, &c. The costs of labour and of materials in jointing the conduits are a considerable item, and since the stoneware conduits are usually in 2ft. or 3ft. lengths, while cast-iron pipes are usually 9ft. in length, there will in general be many more joints of the former than of the latter in a mile run of conduit. However, a stoneware joint can usually be made more cheaply and quickly than a spigot and socket joint in 9ft. lengths of cast-iron pipe. The usual methods of making the joints are as follows. For a cast-iron pipe the spigot end is first pushed home into the socket, and jute drifted into the joint until it is rammed against the flange of the socket. The outer end of the flange is now luted up with a damp clayey rope, clay being plastered around the outside of the rope, so as to close the opening of the socket except at the top. The rope is next drawn out, leaving a clay stopping, and molten lead is poured into the annular space between the spigot and socket. When the lead is set, the clay is knocked off, and the metal drifted tightly into the socket, forming a perfectly tight joint. Messrs. Doulton and Co.'s stoneware conduits, except in the circular form, are generally jointed by abutting the ends on a stoneware chair, and then rendering the joint watertight with Portland cement.

It may be of interest to supplement the foregoing comparison between cast-iron and stoneware conduits with some particulars of the types of conduits, already referred to, which are used at Portsmouth, St. Pancras, Bedford, and in numerous other towns. Fig. 1 shows the type "B 1" of Doulton conduit used at Portsmouth. There are three separate ducts; the one on the left side of the conduit, as seen in the figure, is for the arc light mains; the centre duct is for the feeders; and the remaining duct, which can be covered with the house-service cover shown in the figure, is for the distributing cables. These three ducts are formed in one closed conduit; in the case of the distributing duct the upper portion is connected to the lower part by a thin connection, which can readily be severed by means of a chisel. In the type "B 2," shown in Fig. 2, and used on the St. Pancras three-wire system, the separation of the upper from the lower part can be made in the same manner, the whole of the upper part being removed and replaced by a house-service cover where required. These two forms of

conduit provide separate ducts for the several cables, but where covered cables are used it is often cheaper and more convenient to carry them all in a single conduit, such as that shown in Fig. 3. This form is used at Bedford for the lead-covered low-pressure distributors, the high-pressure mains at that place being in cast-iron pipes.

The construction of street boxes and transformer chambers has not necessarily anything in common with the actual system of conduit used; nevertheless, the materials used in the one are often employed in the other, and a material which possesses qualities rendering it useful in a conduit should in general answer as well the purpose of a small street box. Stoneware and cast iron, more recently than brick and other built-up chambers, have come into use for this latter purpose. On the recently opened Islington system, cast-iron boxes are extensively used, while stoneware has found favour for this purpose at Sunderland. Details are shown in Fig. 4 of the type of Doulton stoneware chamber designed for Sunderland. The chamber or box, without its cover, is in one piece, which can quickly be lowered and set in the excavation. In the form shown there are four ways, but two-way and three way forms may also be used. Opposite entrances to the box are made, the one of larger area than the other. This is to enable a rise or fall in level of the conduit to occur at the box, as the conduit at the larger entrance may be set either at the top or bottom of the entrance, the remaining space being built up with brick. The boxes are fitted with airtight cast-iron cover plates, which are earthed over and covered with the ordinary paving of the footpath.

LONGITUDINAL LIGHT.*

III.—Theory of Electric Phenomena in Rarefied Gases.†

Changes in Rarefied Air by Electric Actions.—The most remarkable property of rarefied air consists in the fact that small actions (variations of energy) produce great variations of properties (temperature, volume, &c.). This is due to the very small capacity of its unit volume for heat and for other forms of energy.

Now it may be supposed that from similar causes electric actions produce a strong change of state of rarefied air. The electric discharge is evidently connected with marked changes of properties of the medium during discharge, or perhaps before it, which cannot be reduced to mere changes of temperature.

I do not intend to make any supposition with regard to the nature of the state which is altered by electric force. But any change of state of the medium is accompanied by a change of its dielectric and diamagnetic constants. The special electric behaviour of rarefied air is due to the fact that electric actions indirectly alter its electric and magnetic constants, and this again reacts upon the course of these actions.

Maxwell's Equations for a Variable Medium.—Since the electric and magnetic coefficients ε and μ in Maxwell's equations are *variable* during the electric action in rarefied air, the equations assume the form

$$\text{(I.)}\quad \begin{cases} \frac{d}{dt}(\varepsilon X)=c_0\frac{d\mathfrak{N}}{dz}-c_0\frac{d\mathfrak{B}}{dy}, & \frac{d}{dt}(\mu\mathfrak{X})=c_0\frac{dZ}{dy}-c_0\frac{dY}{dz}, \\ \frac{d}{dt}(\varepsilon Y)=c_0\frac{d\mathfrak{B}}{dx}-c_0\frac{d\mathfrak{X}}{dz}, & \frac{d}{dt}(\mu\mathfrak{N})=c_0\frac{dX}{dz}-c_0\frac{dZ}{dx}, \\ \frac{d}{dt}(\varepsilon Z)=c_0\frac{d\mathfrak{X}}{dy}-c_0\frac{d\mathfrak{N}}{dx}, & \frac{d}{dt}(\mu\mathfrak{B})=c_0\frac{dY}{dx}-c_0\frac{dX}{dy}. \end{cases}$$

Here X, Y, Z denote components of electric force, $\mathfrak{X}$, $\mathfrak{N}$, $\mathfrak{B}$, those of magnetic force, ε and μ two variables having a simple relation to the electric and magnetic constants ε_0 and μ_0 of the medium, being reduced to them in a state of rest, and c_0 the normal velocity of light.

From the equations (I.) we obtain immediately

$$\text{(I a)}\quad \begin{cases} \frac{d}{dx}(\varepsilon X)+\frac{d}{dy}(\varepsilon Y)+\frac{d}{dz}(\varepsilon Z)=0, \\ \frac{d}{dx}(\mu\mathfrak{X})+\frac{d}{dy}(\mu\mathfrak{N})+\frac{d}{dz}(\mu\mathfrak{B})=0, \end{cases}$$

for in a condition of rest, in which ε and μ become ε_0 and μ_0, these expressions are known to be equal to zero, and by equations I. they suffer no time change by any electrical process.

The very circumstance that Maxwell's equations assume the non-linear form (I.), *when the medium is changed by the process*, brings out the advantage of this supposition. Electric processes would always be simply superimposed if Maxwell's equations were truly linear. But most of the higher electrical processes have a decidedly non-superimposing character (*e.g.*, discharge by light, mutual repulsion of cathode rays, &c.). The method here adopted of depriving Maxwell's equations of their linearity can hardly be surpassed by any other.

Influence of Great Constant Forces.—If the charges $d\varepsilon/dt$ and $d\mu/dt$ have not to be considered, Maxwell's equations are linear, and represent the elementary optical phenomena.

But even in media in which the changes $d\varepsilon/dt$ and $d\mu/dt$ have high values, pure superimpositions of radiation phenomena are possible, namely, when the static forces X_0, Y_0, Z_0 and $\mathfrak{X}_0$, $\mathfrak{N}_0$, $\mathfrak{B}_0$ present are of such magnitude that the changes brought about by the process considered $(X-X_0)$, $(Y-Y_0)$, &c., vanish in comparison, and $(\varepsilon-\varepsilon_0)$ also vanishes in comparison with ε_0 and $(\mu-\mu_0)$ with μ_0. In this case Maxwell's equations assume the following form:—

$$\text{(I')}\quad \begin{cases} 1.\ \varepsilon_0\frac{dX}{dt}+X_0\frac{d\varepsilon}{dt}=c_0\frac{d\mathfrak{N}}{dz}-c_0\frac{d\mathfrak{B}}{dy}. \\ 2.\ \varepsilon_0\frac{dY}{dt}+Y_0\frac{d\varepsilon}{dt}=c_0\frac{d\mathfrak{B}}{dx}-c_0\frac{d\mathfrak{X}}{dz}. \\ 3.\ \varepsilon_0\frac{dZ}{dt}+Z_0\frac{d\varepsilon}{dt}=c_0\frac{d\mathfrak{X}}{dy}-c_0\frac{d\mathfrak{N}}{dx}. \\ 4.\ \mu_0\frac{d\mathfrak{X}}{dt}+\mathfrak{X}_0\frac{d\mu}{dt}=c_0\frac{dZ}{dy}-c_0\frac{dY}{dz}. \\ 5.\ \mu_0\frac{d\mathfrak{N}}{dt}+\mathfrak{N}_0\frac{d\mu}{dt}=c_0\frac{dX}{dz}-c_0\frac{dZ}{dx}. \\ 6.\ \mu_0\frac{d\mathfrak{B}}{dt}+\mathfrak{B}_0\frac{d\mu}{dt}=c_0\frac{dY}{dx}-c_0\frac{dX}{dy}. \end{cases}$$

These equations are linear, hence radiations may be superimposed.

But the constant forces and the forces of the radiation do not superimpose, since the constant forces appear as coefficients in the equations; different radiations, on the other hand, which take place in the same constant field, do superimpose.

Rarefied air also conforms to the original Maxwell theory when no great constant forces pervade it and the amplitude of the radiation is very small. But for radiations of high amplitude it obeys equations (I.) even in the absence of constant forces, and therefore admits of longitudinal rays.

Rarefied air, however, in which large constant forces are present, *has a special behaviour even for the feeblest radiations*, and obeys the equation (I').

The remarkable dependence of the cathode rays upon the constant electric and magnetic field strength here results already from the theory, and is caused, according to (I'), by the fact that in rarefied air $d\varepsilon/dt$ and $d\mu/dt$ do not vanish in comparison with the time-changes of the forces, even for the feeblest radiations.

This is the fundamental difference between my own longitudinal waves and those of Helmholtz, whose longitudinal waves behave like sound-waves as regards superposition, so that constant forces are of no importance. The difference of species which gives the cathode rays their name cannot be explained if the constant changes of the electrode defining this difference are irrelevant.

I believe I have now sufficiently proved the convenience of the fundamental supposition that ε and μ are changed by electric processes in rarefied air.

Cause of the Variability of ε and μ.—We must now establish two essentially new equations for the new variables ε and μ. These equations may be understood and formulated in such a manner that they give as the cause of the time change of these variables a certain function of the forces.

There are indeed no direct observations upon the variability of ε and μ during electric processes. But probably no such variability could be discovered at all without theoretical assistance, on account of the rapidity of all processes which may bring it about.

But theoretical considerations may lead to the establishment of the equations for $d\varepsilon/dt$ and $d\mu/dt$ without a direct foundation. Their success depends upon whether these variations occur under the direct influence of the forces. Only direct and simple connections may be guessed at by their form or by comparisons of physical processes.

Provisional Conclusion Concerning the Required Equations from the Formal Requirements.—Explicit equations for $d\varepsilon/dt$ and $d\mu/dt$ are sought, which give certain functions of the forces as the causes of these changes.

* *Wied. Ann.*, 57, 1, pp. 147—184, 1896.

These functions must be constituted in an approximately linear manner from derivations from the force components of the first order. That is required by the possibility of approximately undamped rays.

These derivations must be *spatial*, since otherwise rays of indefinite velocities of propagation become possible.

The whole function, *i.e.*, the sum of these derivations must be invariant and scalar during changes in the system of co-ordinates, for it is equal to the invariant and scalar expressions $d\varepsilon/dt$ and $d\mu/dt$.

This refers us to Laplace's expressions, and we may suspect the following equations :—

$$\left.\begin{aligned}\frac{d\varepsilon}{dt}&=\frac{d\mathrm{X}}{dx}+\frac{d\mathrm{Y}}{dy}+\frac{\mathrm{Z}\,d}{dz}\\ \frac{d\mu}{dt}&=\frac{d\mathfrak{X}}{dx}+\frac{d\mathfrak{Y}}{dy}+\frac{d\mathfrak{Z}}{dz}\end{aligned}\right\}\text{not valid.}$$

It is at once recognised as a point of agreement that the condition for the appearance of longitudinal waves is the non-disappearance of $d\varepsilon/dt$ and $d\mu/dt$, and that purely longitudinal waves are necessitated by the disappearance of Laplace's expression.

This formal reasoning is, of course, founded in all its details upon the supposition of the greatest possible simplicity of the relation sought for. It has proved later on to be not strictly applicable, and incorrect in one principal point. But it contains the correct reference to Laplace's expression, and it at once gave a good direction to the following reasoning.

On the Material Changes accompanying Vectorial Processes.—Let us first ask the question whether a direct dependence of ε and μ from the electric and magnetic forces is not in itself unthinkable.

It would, for instance, change the sense of all mechanical equations if we were to assume that the density ρ of a body was a direct function of its velocity components Ξ, H, Z. Such a supposition is excluded, since even at the highest velocities projectiles, for instance, retain their masses.

Still the following differential equation is valid, and contains no contradiction.

$$\text{(IIa)}\qquad \frac{d\rho}{dt}=\frac{d}{dx}(\rho\Xi)+\frac{d}{dy}(\rho\mathrm{H})+\frac{d}{dz}(\rho\mathrm{Z}).$$

It is my opinion that this equation is a special case of a much more general principle governing all vectorial processes.

Equation for the Change of the State σ.—The relation between the change of density and the distribution of velocity is so characteristic of mechanics that it must be assumed that the other vectorial processes are not without a similar effect, if indeed there is any quantitative analogy between mechanical and electrical processes. But this nobody will doubt. Here we have one of the strongest foundations which can be given to any theory.

There must be an electric equation exactly corresponding to the equation (II*a*) of the form

$$\text{(II.)}\qquad a_0\frac{d\sigma}{dt}=\frac{d}{dx}(\sigma\mathrm{X})+\frac{d}{dy}(\sigma\mathrm{Y})+\frac{d}{dz}(\sigma\mathrm{Z}).$$

Here we have, instead of the velocities of equation (II*a*), the components of electric force. This is the most natural analogy. If it should yet contain a fault, this may easily be discovered and corrected afterwards.

Instead of the density ρ, we have a *new physical variable* σ, whose nature is only indicated later on. It is essentially *scalar*, and may be analogous to density, pressure, or temperature, &c. a_0 is an essentially positive reduction factor, as will be shown, whose dimensions are those of an electric force divided by a velocity. Its magnitude and sign only depends upon the usual reckoning of the forces, but not upon the nature of the medium. The equation (II.) obtains in an equal manner for all media.

Connection between ε *and* σ.—All physical conditions depend upon each other ; all properties of bodies are functions of the temperature, the pressure, &c. ; they are, indeed, functions of each other. If this were not the case, the formal conclusions above would have misled me, but not in the direction of equation (II.*a*). It might have been supposed that ε and σ are interdependent ; it follows from the form of the energy equation, σ is the analogue of the density ρ. The kinetic energy of a volume element is represented by $\frac{1}{2}\rho(\Xi^2+\mathrm{H}^2+\mathrm{Z}^2)\,dx\,dy\,dz$.

The electric energy of a volume element is therefore determined as (III.) $\mathrm{E}=\frac{1}{2}\sigma(\mathrm{X}^2+\mathrm{Y}^2+\mathrm{Z}^2)\,dx\,dy\,dz$.

It is known to be determined by ε_0 in a condition of rest

$$\mathrm{E}_0=\tfrac{1}{2}\varepsilon_0(\mathrm{X}^2+\mathrm{Y}^2+\mathrm{Z}^2)\,dx\,dy\,dz.$$

Hence it follows that ε and σ must be actually equal in a state of rest.

$$\text{(IV.}a\text{)}\qquad \varepsilon_0=\sigma_0.$$

But a simple equality cannot subsist between ε and σ except in a state of rest. For if σ were always equal to ε, the change $d\varepsilon/dt$ by equations (I.*a*) and (II.) would always have to be zero, and the theory would be reduced to that of Maxwell. After equality the following relation is the simplest :—

$$\text{(IV.)}\qquad \varepsilon-\varepsilon_0=\eta_0(\sigma-\sigma_0).$$

Here η_0 is a constant depending upon the *nature of the medium*. The correctness of equation (IV.) is immediately recognised by the following agreement. Equation (IV.) must first of all fulfil the condition that for a simple value of η_0 (say 0 or 1) the theory is reduced to that of Maxwell.

Now this takes place when $\eta_0=1$ or $\eta_0=0$, but for no other value of η_0.

For $\eta_0=1$ we have $\sigma=\varepsilon$ and equation (IV.*a*). But with a simple equality of σ and ε the theory, as already stated, reduces itself to the Maxwellian form.

For $\eta_0=0$, σ would have to be $=\infty$ in order that ε may differ from ε_0. But by equation (II.) σ can only assume infinite values by infinite forces or discontinuities. For $\eta_0=0$ we therefore have $\varepsilon=\varepsilon_0$, which also leads us to Maxwell's theory.

If we assume that for all ordinary dense bodies the Maxwellian theory, including the energy equation, is valid in every respect, η_0 for these bodies is also unity.

But when the air is rarefied the value of η_0 diminishes, and longitudinal waves become possible. In an absolute vacuum η_0 becomes equal to zero. In this extreme case longitudinal waves become impossible once more.

η_0, therefore, has an essentially positive value for rarefied gases which lies between 0 and +1, according to the density of the gas ; for dense bodies it has a value closely approaching +1.

From (II.) and (IV.) the following equation follows, if we bear in mind that the expression (I.*a*) has a constant value by (I.) :—

$$\text{(II'.)}\qquad \frac{a_0}{\eta_0-1}\frac{d\varepsilon}{dt}=\frac{d}{dx}(\varepsilon_0\mathrm{X})+\frac{d}{dy}(\varepsilon_0\mathrm{Y})+\frac{d}{dz}(\varepsilon_0\mathrm{Z}).$$

This is the required equation, which represents the charge $d\varepsilon/dt$ as a function of the force distribution.

It will be seen that it also applies to media which are non-homogeneous in a state of rest. It naturally fulfils for the state of rest, *i.e.*, for $d\varepsilon/dt=0$, the following well-known condition (which does not, however, form the basis of the present considerations):—

$$\text{(1)}\qquad 0=\frac{d}{dx}(\varepsilon_0\mathrm{X})+\frac{d}{dy}(\varepsilon_0\mathrm{Y})+\frac{d}{dz}(\varepsilon_0\mathrm{Z}).$$

The equations (I.), (II.), (III.), (IV.) and (V.) express the theory perfectly. The relation (1) is a deduction from this theory.

(To be continued.)

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-day) FRIDAY, March 13th.

PHYSICAL SOCIETY.

5 p.m. Meeting at Burlington House. Papers to be read.: (1) "An Addition to the Wheatstone Bridge for the Determination of Low Resistances," by J. H. Reeves ; (2) "On Cathode Rays," by Herr Puluj.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Students' Meeting in the Library of the Institution. Discussion on Mr. Fennell's Paper on "Some Central Station Experience."

SATURDAY, March 14th.

INSTITUTION OF ELECTRICAL ENGINEERS.

Students' Visit to Messrs. Siemens Bros. and Co.'s works at Charlton. Train leaves Charing Cross at 10:20 a.m., Cannon-street 10:30, and London Bridge 10:33. Book to Charlton Junction.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture (IV.): "Light," by the Right Hon. Lord Rayleigh, F.R.S.

TUESDAY, March 17th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Three Papers dealing with Metallurgy will be read.

FRIDAY, March 20th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Students' Meeting in the Library of the Institution. Paper to be read : "Some Distinctive Features of Continental Engineering Practice," by K. Edgcumbe and E. J. Fox.

SATURDAY, March 21st.

SPECIAL NOTICE.

With this week's number of "THE ELECTRICIAN" is issued (gratis) a Supplement Sheet Table showing Total Outlay and Receipts and Expenditure for the year 1895 of Statutory Electric Supply Undertakings in London and the Provinces. Additions will be made to the Table as further accounts appear, and the Table will be issued from time to time. Complaints of non-receipt should be promptly addressed to the Publisher.

THE AUDIT OF ELECTRIC LIGHT COMPANIES' ACCOUNTS.

The audit of the accounts of electric light undertakings has been referred to in these columns on several occasions recently (see *The Electrician*, December 27, 1895, p. 299, January 10th, pp. 333 and 356), and it has once or twice been fitfully discussed at shareholders' meetings. The question has now been brought to a head, so to speak, by the action of the shareholders of the Westminster Electric Supply Corporation, who at their last general meeting unanimously passed a resolution to the effect that the Board of Trade auditor should act in the dual capacity of official auditor and shareholders' auditor. By taking this step it is sought to effect a small economy, and avoid the inconvenience of reopening the Company's books after they have been approved by the Board of Trade.

The grievance of which the shareholders of electric lighting companies have complained is, it seems to us, a very real one, though rather theoretically important than actually so. Like the generality of limited liability concerns, electric lighting companies are bound by their Articles of Association to appoint an auditor. In addition to this indispensable functionary, however, the Board of Trade, under Section 9 of the Electric Lighting Act of 1882, is also empowered to appoint an auditor. Under a sensible dispensation this irritating duplication of functionaries with functions of a similar nature would not have occurred. At any rate, the shareholders of the Westminster Electric Supply Corporation mean to try and avoid paying two men for what is practically the same job. But, unfortunately, in view of the letter of the Board of Trade dated December 18, 1895, addressed by that Department to the Secretary of the Institute of Chartered Accountants, it seems very doubtful whether in the existing state of the law the resolution passed at the recent meeting of the Company is worth the paper it is written on.

Digitized by Google

We have always inclined to the opinion that for two distinct auditors to go through the accounts of an electric light company in quick succession is a work of supererogation, and, so far as the company itself is concerned, absolutely unnecessary. Moreover, unless considerable care and discretion is exercised by both auditors, friction is bound, sooner or later, to take place, and serious difficulties to arise. As things are now there are two auditors acting with somewhat different objects in view. The shareholders' auditor is appointed by the shareholders, and one of his principal duties consists in satisfying himself that no amounts are charged to capital which are properly chargeable to revenue. On the other hand, one of the chief duties of the auditor appointed by the Board of Trade is to make sure that no amounts are charged to revenue which are, in his opinion, in the nature of capital expenditure. During the progress and development of any large undertaking, more especially of a business such as an electric light undertaking in its early days, many items of expenditure must inevitably be of a debatable nature even when regarded from the same point of view by two different individuals, and much more so when regarded from somewhat different points of view. For whereas one auditor, in the interests of the shareholders, would look with a lenient eye upon items charged to revenue, the other would be inclined, in the interests of the Department which he represents, to be satisfied if the debatable items were chargeable to capital. Again, it is no part of the duties of the Board of Trade auditor under the Act of 1882 to concern himself with the floating assets of a company. If the Reserve Fund investments were wrongly appropriated it would be no concern of his. Again, he need not trouble himself as to the proper disposition of any cash balances either in hand or temporarily invested. With two auditors actuated by different motives what will happen when they are at issue? The shareholders' auditor will probably hold to his opinion and the official auditor to his, whilst the directors will, in all likelihood, issue the accounts in accordance with the views of the former, notwithstanding the objections of the latter. These incidents having once occurred, the official auditor cannot certify to the Board of Trade as correct any subsequent accounts, since these will have embodied in them items the treatment of which he does not endorse. The investing public will soon hear that the Board of Trade does not approve of the way in which the company's books are kept, and it is not difficult to foresee that this will indirectly have an adverse influence upon the financial status of the concern in question—an argument more cogent than that of mere economy, for endeavouring to combine the duties of the Board of Trade and shareholders' auditor in one and the same individual.

Although it is not compulsory under the Companies Act of 1862 for electric light concerns to appoint an auditor, the articles of association of all the companies contain the very necessary provision that an auditor shall be appointed by the shareholders. If, however, the official auditor does not or cannot offer himself for this post, it would seem that shareholders, to put themselves in order, must at least pass a resolution altering the articles of association so as to enable them to accept the audit of the Board of Trade as sufficient for their purpose. As matters stand the resolution recently passed by the shareholders of the Westminster Supply Corporation, although useful as a protest against the imposition of a double audit, or rather, as a protest against having to pay for the same, does not seem quite regular, and the auditor's fee of 50 guineas saved by the thrifty shareholders will be a mere nothing as a solicitor's solatium. If piling audit upon audit would appreciably add to the serenity of the investors' state of mind the extra cost would not be cavilled at. But whenever the State imposes an audit for a special State purpose upon a commercial concern, it ought in common fairness to try and make its special audit also meet the wants of the average shareholder.

REVIEWS.

Electro-Metallurgie. Die Gewinnung der Metalle unter Vermittlung des Elektrischen Stromes. By Dr. W. Borchers. (Published by Harold Bruhn, Brunswick.)

The rapid and substantial growth in many branches of electro-metallurgy which has taken place of late years has made the publication of a comprehensive and authoritative text-book an event to be welcomed. Dr. Borchers' work in its new and enlarged form may fairly lay claim to be a book of this scope and rank.

Before proceeding to detailed criticism some idea of the nature and extent of the ground covered by this treatise may be conveniently imparted. A glance at the table of contents reveals a notable fact. The author is not content with describing the methods of electrolysis available for the separation of those metals which at the present moment find commercial application. He deals also with those, such as beryllium (glucinum), cerium and uranium, which have not yet been utilised in the metallic state. The facts given concerning metals of this class accurately reflect existing knowledge, and suffice to indicate the direction in which investigation may be usefully prosecuted when the increasing abundance of the raw material or the augmenting demand for the finished product justifies the attempt to bring the winning of these rarer forms of matter within the category of industrial pursuits. Consonant with this catholicity of view is the intelligence of arrangement of the book as a whole. The work begins with a short but clear description of the principles of electrolysis and of the conditions determining the relations of thermal to electrochemical energy. In this, the theory of electrolytic dissociation is adopted *sans phrase*, and is amply expounded as far as space allows and necessity demands. Seeing that the hypothesis is as plastic as it is ingenious, it can be applied to facts long established without suffering patent fracture, but as a guide in electro-metallurgical practice it is not wholly trustworthy, and Dr. Borchers gives due warning that cases may occur where its foreshadowings must be disregarded. Not every author pinning his faith to fashionable opinions is equally temperate and candid. There is that about a clever generalisation which often blinds its believers, reducing them to the intellectual level of religious fanatics; the receptive and the critical are ever at variance.

Succeeding sections of Dr. Borchers' book treat of the metals of the alkalies and the alkaline earths, and of the metals of the earths proper, aluminium taking first rank but being suitably followed by those metals which cosmical accident has made rarer, viz., cerium, lanthanum and didymium. With these the first volume is completed. The second and larger volume deals with what may be fairly ranked as heavy metals, or metals usually extracted from recognised ores and not from such saline or earthy substances as salt, chalk and bauxite. Besides metals like copper, silver, zinc and nickel, which are generally viewed as fit subjects for electrolytic separation, others commonly ignored—*e.g.*, chromium, manganese and molybdenum—are not neglected. Space is allotted to them in proportion to what is known of their behaviour in an electrolytic cell, and what may be fairly expected of them as materials for use.

Coming to a more detailed consideration of the contents of this work, we find a sound system adopted, in that a condensed but intelligible description of the chief properties and chemical methods of preparation of each metal precedes the discussion of processes for its separation by electrolysis. Further, something is said of the uses, actual and prospective, of the less common metals. Thus, we find under the head

Digitized by Google

of "Magnesium" not only mention of its employment as a deoxidising agent for nickel, conducing to the production of sound castings, but also the information that the reason for preferring it to aluminium is that any magnesium in excess of that necessary to bring about the reduction does not alloy with the nickel. Beryllium, as becomes a metal which, in spite of its resemblance to aluminium, is divalent, is grouped with magnesium. The alkali metals, especially sodium, are treated at length, although practically all the sodium now manufactured is prepared by purely chemical processes. The development of the best existing methods is traced from early times, and it is pointed out that in the classical experiments of Davy the important principle of causing a metallic containing vessel to function as one of the electrodes was recognised and applied. The idea subsequently adopted by inventors of distilling the sodium from the apparatus as quickly as it is separated is of dubious value, on account of the high boiling point of the metal (742° C.), and is quite impracticable for metals of the alkaline earths, which are fixed at ordinary furnace temperatures. The chapter is written in a style pleasingly caustic, and, while recording many devices which have not got beyond the patent stage, does not fail to call attention to their weak points and causes of failure; from them as much may be learned as from the positive merits—and they are not a few—of the ingenious apparatus which have been designed and forgotten. After laying down the conditions which must be fulfilled by any apparatus capable of preparing sodium by electrolysis with commercial success, the author describes one of his own planning, which appears more rational than most others, and appends an estimate, giving the cost of the sodium produced as M.2·3 per kilogramme—*i.e.*, about 1s. per lb. Under the head of sodium alloys, the Castner-Kellner method, for manufacturing caustic soda and chlorine by the use of mercury as an intermediary between the two electrodes, is spoken of, and the originality and utility of the Vautin process (in which lead is used as a cathode, and a lead-sodium alloy is obtained) are strenuously disputed. The preparation of barium, strontium and calcium is still a matter of difficulty, even in the laboratory, for the conflicting conditions that the temperature of the electrolyte should be low and that of the cathode high, have to be provided for. A high-current density—*e.g.*, 500,000 to 1,000,000 amperes per square metre—is a necessity, and is attained, as in Bunsen's original researches, by the use of a mere wire as the cathode. Unfortunately, the very success of the operation of electrolysis involves the separation of metallic globules at the cathode, which increase its surface, diminish the current density and lower the temperature. We note, by the way, that Dr. Borchers lends some countenance to the existence of hypothetical subchlorides—bodies of very doubtful character. An appendix to the section on the metals of the alkalies and alkaline earths gives an adequate account of calcium carbide and it congeners; a perfectly reasonable estimate of cost is given, and a use is suggested for CaC_2 in the refining and deoxidation of industrial metals. We may mention that calcium carbide has already been tried as a carburising material for ingot iron and has proved useless.

To the chapter on aluminium some 60 pages are devoted. Reduction of aluminium and simultaneous formation of alloys occupy the first portion, but the true electrolysis of aluminium salts for the winning of the metal unalloyed, is naturally the more interesting part. Dr. Borchers administers one more swashing blow to that evergreen myth the deposition of aluminium from aqueous solutions, but we rather expect to hear of it again; certain worthless entities die hard. In the historical description of the electrolysis of fused aluminium salts it is interesting to note that Davy tried to reduce the oxide electrolytically, but only succeeded in preparing an iron-aluminium alloy. Bunsen was the first to succeed, using the double chloride of aluminium and sodium to which sufficient common salt had been added to raise the temperature of the bath above the melting point of aluminium and thus allow the metal to collect. Pursuing the subject steadily through its many bye-ways, the author finally shows that, as it proved impracticable to obtain a material from which a vessel could be prepared capable of being heated from without and of withstanding the action upon it of the fused electrolyte, inventors were at last driven to induce and maintain fusion of the electrolyte by the use of a high current density. The author attributes the first clear statement of the principles upon which all modern methods of reducing aluminium are based, to Heroult in his French patent, No. 170,003 of 1887. He examines the patents of Hall and Minet, and concludes that they do not cover those requirements which are essential for successful work, and that those alterations which have converted them jointly into a practical manufacturing method are covered by and included in the specifications filed by Heroult. In discussing the merits and drawbacks attending the use of aluminium sulphide as an electrolyte in place of alumina, the author appears disposed to consider that the great technical difficulty of preparing the former substance will prevent its adoption on a large scale. Finally, he lays down certain conditions for the successful performance of the electrolysis of aluminium salts. These may be summarised thus:—The electrolyte should consist of a solution of alumina in the fused haloid salts of the metals of the alkalies, alkaline earths, and of aluminium itself; the content of the electrolyte in alumina should be maintained constant during electrolysis; the anode should be of carbon and the cathodes of metal, cooled by water circulation or some similar device; the vessel containing the electrolytic bath should be of iron, lined with some refractory aluminium compound; the heat necessary to fuse the electrolyte should be obtained by the use of a current density as high as 25,000 amperes per square metre at the cathode; the lining of the electrolytic bath must be kept cool enough not to dissolve in the electrolyte; the temperature of the electrolyte should be kept as low as possible, both to avoid possible re-solution of the separated metal and volatilisation of the alkali salts forming part of the bath.

The first volume, to which we have devoted much space on account of the fact that it deals with many of the most weighty problems now in process of solution by those engaged in electrolytic industry, concludes with an account of the methods that avail for the reduction of the rare metals, cerium, lanthanum and didymium.

In the second volume of this treatise one becomes conscious of being on somewhat more explored ground than that covered by the first part of the book. In dealing first with copper, Dr. Borchers, as is his wont, briefly describes the more usual metallurgical methods before proceeding to the consideration of electrolytic processes. He draws a necessary distinction between the electrolytic refining of copper of moderate crudeness and its extraction from matte and ore. The influence of impurities in copper to be refined, on the conduct of the process and the character of the product, is not overlooked; thus, copper containing cuprous oxide is apt to become covered with a film of this substance, which is a poor conductor; sulphide and selenide of copper are left with the anode sludge; the presence of tin seems to favour the separation of copper in the form of a layer more uniform and coherent than that thrown down in pure solutions, an effect long taken advantage of in the art of electrotyping. Passing to the section dealing with the extraction of copper, as distinct from its refining, we find an excellent description of the ill-starred Marchese process, the successive modifications of which, with their advantages and ultimate failures, are recorded in a lively and lucid manner. The only process which seems to have reached anything resembling a commercial footing is the Siemens-Halske, and even in this case much more is said about its modifications than of its applications. The Hoepfner process, attractive from its utilisation of the reducing power of the ore to produce an electrolyte containing the copper in the cuprous state, has seemingly also fallen short of an industrial status. Singularly enough, the fundamental reaction, according to which copper sulphide is represented as being able to reduce cupric to cuprous chloride with reasonable speed, appears to have been accepted (save in this country, where Mr. Swinburne has doubted its validity) without question. The old difficulty of obtaining a reliable anode and diaphragm seems largely responsible for the abortive outcome of the Hoepfner process.

Few but those interested in the trade in precious metals realise the nature and extent of the changes which have occurred in their technical treatment. The displacement of parting by means of nitric acid by the cheaper process of solution of the silver in hot strong sulphuric acid was a considerable step; the present tendency to effect a separation by electrolysis is even more notable. In handling the precious metals there is the great advantage that a deposit in a finely divided state can be fused into an ingot without sensible loss. It is therefore unnecessary to attempt the attainment of a coherent coating on the cathode, and the current density may be high, a matter of importance as the interest on the value represented by the weight of metal under treatment is a serious item in the cost of the process. In treating gold, the author has but little good to say of those processes in which the aid of current is invoked to help the extraction of metal from the ore, or from that richer vein, the pockets of the public. Much space is devoted to the consideration of the advantages of the Siemens process for recovering gold from cyanide liquors in the manner now in use on the Rand. We are disposed to think, however, that the author takes rather too optimistic a view of the capabilities of the process in comparison with those of the ordinary method of precipitation by means of zinc. Decision of the relative merits of these rival recovery processes is eminently a matter to be settled by every-day working on a large scale; it is not difficult to make out a good case for either, and to condemn the other in a convincing manner.

The chapter on zinc is one of the best in the book, and is worthy of special study at the present time, when schemes for the electrolytic treatment of ores containing zinc are much in evidence. As far as can be gathered from published accounts, the winning of zinc by electrolysis has not gone beyond the stage of large-scale experiment; a works remuneratively running has yet to be found. Nevertheless, the principles upon which successful extraction must be based are well understood, and there is good reason to hope that they may soon be generally applied. As far as the refining of zinc is concerned, we learn that the zinc-silver-lead alloy obtained by the use of zinc containing 0·5 per cent. of aluminium in the Parkes process for desilverising lead, is being worked up for zinc by electrolysis in a bath of zinc chloride and magnesium chloride, the lead and silver being left undissolved at the anode. The reason for the precipitation of zinc in a spongy state is said to be want of slight acidity of the electrolyte, and too low a current density; coherent reguline zinc may be obtained, but commonly with some waste of electrical energy expended in the evolution of hydrogen at the cathode. An ingenious apparatus, somewhat resembling that used for the reduction of aluminium by the Heroult process, has been designed by the author for the production of zinc and chlorine from zinc chloride kept fused by the use of a high current-density.

There is little prospect of any electrolytic process for winning tin from its ores replacing existing metallurgical methods, but it is somewhat surprising to find that the refining of commercial tin (usually containing only 99—99·5 per cent. of Sn) is not practised. More attention has been paid to the stripping of tin plate scrap. Acid baths have many failings, and for this reason caustic soda, made conductive by the addition of common salt, is to be preferred. Thus worked, the recovery of tin from scrap is likely to be remunerative. The profitable reduction of lead and even its ordinary refining are not likely to be carried out by electrolytic methods. Commercial lead contains 99·98 per cent. or more of Pb, and room for improvement is therefore scanty. The separation of bismuth from lead containing a tangible quantity of that metal, by electrolysis in a bath of fixed chlorides, has some prospect of success. For the extraction of antimony from poor sulphide ores, a process consisting in the extraction of the ore with sodium sulphide and the electrolysis of the resulting thio-antimonate is described, but it has not passed the experimental stage. There is only a trifling demand for pure chromium and manganese, their respective iron alloys sufficing for the chief purpose to which these metals are put, but, in the event of need arising, there should be little difficulty in meeting it. Both chromium and manganese can be reduced from their aqueous solutions when a high current-density is used, but the manufacture of manganese on an industrial scale would be best performed in the way commonly used for aluminium. The electrolytic refining of ferro-chromium and ferro-manganese has been tried without much success. Iron comes within the field of electro-metallurgy chiefly in respect of the magnetic dressing of its ores and the working of finished iron by various welding processes; electrolytic refining has been proposed but remains to be achieved. The tendency of nickel to scale when the deposit on the cathode is more than a film, has proved an obstacle to the electrolytic winning or refining of a metal which in some respects appears well fitted for such treatment.

Having thus given some account of the contents of Dr. Borchers' work, a few words will suffice for a summary of our opinion concerning it. The book is not only full of valuable information, but it gives evidence of a practical acquaintance on the part of the author with many of the processes which he describes, and of a thorough insight into the technical value and possibilities of all the methods which he discusses. Considering the vast quantity of rubbish which the compiler of such a work must excavate to get at his facts, the book is singularly little burdened with descriptions of worthless patents. Many abortive schemes are described, but their insertion is justified by the illustrations they afford of the difficulties which inventors may expect to encounter and the warnings they give of attractive courses leading straight to limbo. As is not unnatural, Dr. Borchers is somewhat disposed to take a rosy view of the prospect of many electrolytic methods which, to live, must fight hand to hand with long-established and well-devised chemical and metallurgical methods, and he scarcely insists sufficiently on the high cost of power and plant inseparable from electrolytic work. No doubt he himself is fully alive thereto, but for the student and inventor this fact cannot be stated too explicitly or with too much iteration. This, however, is a small blemish on a book which, as a whole, we can commend without reservation. B. B.

Aluminium. By A. G. Brown. (London: The Aluminium Supply Company. 1896.)

The Aluminium Supply Company, who are agents for the Pittsburg Reduction Company of America, have recently issued a cloth-covered *brochure* describing the uses of aluminium and its manufacture by the Hall electrolytic process at Niagara and elsewhere. We have puzzled for some time over the first page of this book, wondering whether it is intended as a title page or as an advertisement. It does double duty. On the next page a mild shock was reserved for us where we made our first acquaintance with the slangy word "alium." It is seriously suggested that this word is a useful and rational substitute for "aluminium," a suggestion from which we dissent. The two words equally divide the attentions of the writer, and vary any monotony by occurring in the most curious sequence throughout the book. There are numerous tabulated data of aluminium, and the inevitable tables of areas of aluminium circles, &c. There are also some illustrations showing views of Niagara Falls, some pots and pans which can be made of aluminium, and of the three-phase plant used at the reduction works. Without doubt this little work contains a great deal of useful information about an engineering material the uses of which are continually extending.

STEREOSCOPIC RÖNTGEN PICTURES.

BY ELIHU THOMSON.

Whilst experimenting with the making of shadow pictures, it occurred to the author that it would be desirable to secure some indication of the position in space of various embedded solid objects, or, in other words, to obtain a pair of pictures which when placed in a stereoscope would show solidity. This would manifestly be useful in surgical examinations, as the true relations in space of the parts of a bone, or of a foreign body and the bone, would become evident. The ordinary Röntgen pictures are simple shadows on a plane surface. It is impossible to tell from such a shadow whether one object or

Digitized by Google

part of an object is front or back of another. There is, however, no difficulty in determining the real positions when resort is had to the production of stereoscopic shadow pictures.

The first trial made by the author was completely successful, objects appearing in high relief. The process consists simply in exposing a covered plate in the ordinary way, and repeating this with the objects and Crookes tube relatively displaced somewhat from the first position. The rays thus pass through the objects in two somewhat different directions, a record of the shadows being made for each direction. Prints from the negatives so produced are mounted for use in the stereoscope. The effect is very curious. A cork or block of wood having nails or screws driven into it in various directions is clearly shown, and the screws or nails in their proper positions. When two heavily insulated wires twisted together constitute the object, the metal wires alone are seen, but standing apart in space, one around the other. The bones of two superposed figures are to be seen in their correct positions. The complete skeleton of a mouse, or other small animal, may thus be recorded so as to be seen in relief, each bone in its proper space relation to the others.

It may be possible as a development of the use of Röntgen rays stereoscopically to arrange two fluorescent screens, or even a single screen, to be viewed by the eyes and receive the image or shadow in such manner as to produce the stereoscopic effect; thus, if the Crookes tube have two cathodes a certain distance apart, which are connected to the electric source alternately, and with considerable rapidity, while small shutters are synchronously opened and closed before each eye respectively, one of the eyes would at all times receive the impression given by the rays from one of the cathodes, while the other eye would always receive the impression produced by the rays from the other cathode, and thus stereoscopic observations would be the result. This method of producing the stereoscopic effect is similar to one which has been tried and used successfully in stereopticon work; two lanterns being arranged to throw upon the same screen in nearly superimposed positions two slides which are stereoscopic in their relation to each other. A set of diaphragms were arranged, passing in front of the lantern tubes synchronously with similar diaphagms passing before the eyes of the spectators, whereby each eye always received its appropriate image on the screen, the result being to give solidity to the scene depicted.

THE DEVELOPMENT OF ELECTRIC LIGHTING ENGINES.*

BY H. LINDLEY.

In acceding to a request to write a Paper on Steam Engines, to be read before this Society, I need hardly say my feelings were to a considerable extent tempered with hesitancy and doubt, for I could not help feeling my own unworthiness for such a task. And here let me say that I do not intend, if I can avoid it, to express any preference on my own behalf for any particular type of engine, but shall, I hope, deal impartially with those that now find use for electric lighting. Having mentioned the word "type," let me therefore, first of all, make an attempt to divide the various kinds of engines now in use for electric lighting purposes into some sort of divisions or classes. I do not claim any originality when I say that a very obvious method of division would be by reference to the speeds of the engines under consideration. We will, therefore, say there are three classes—viz., slow speed, moderate speed and high speed. There is also another motor which we can hardly call a steam engine, though perhaps it might be difficult to say why, and which, therefore, and also on account of its enormously high speed, forms a class by itself, and which does not come within the scopeof this Paper.

Now, the engines to which this Paper refers are what we may call ordinary engines—viz., having cylinders, pistons, &c.; and the speed referred to is the speed of rotation of the crank shaft. Another speed very frequently referred to when speaking of steam engines is that known as piston speed—it should be strictly known as mean or average piston speed, but plain piston speed is enough for our purpose, being a term familiar to you all and well understood. Now, it is rather a singular thing that this piston speed varies but slightly in the various classes of engines we are now considering. You are just as likely to find a high piston speed in a slow-speed engine as you are in a high speed one, if anything rather more likely; there is then some connection of the inverse kind between rotation speed and piston speed, and that is, of course, the stroke: that is to say, the slow-speed engine has a long stroke, the moderate speed a shorter stroke, and the high speed a still shorter stroke. Now, I do not think I need make any attempt to discover and tell you what are the advantages or objections to slow or high speed—it does not enter into the object of this Paper to do so, and no doubt you are as well aware of them as I am, or better. I should, however, be very glad to hear, in any discussion there may be, the opinions of those who have engines under their charge, on the question of engine speed; all I wish to say is that, *per se*, slow speed has certainly obvious objections, and yet for some reason or other slow-speed engines are to-day still much used for driving high-speed electric lighting machinery. Now, I do not think it is difficult to find an adequate reason for this, and that is that it is in the nature of a legacy from past ages. In the old days, before electric lighting became a burning question, suppose a man had a few machines to drive—say a saw bench or two, or some beetling or drying machines, or a few engineers' tools—and he wanted to put down an engine for the purpose, what did he do? Well, I venture to say, as a general rule, he tried hard to remember some other shop about the same size as his own, and the size of the engine that was driving it. Well, we will suppose that an engine of the size so arrived at was put in, and if it drove the shop easily, and without undue heating or excessive repairs, it was accounted a good and well-made engine. On the other hand, if the engine heated badly, knocked, and wanted constant repairing, it was either a bad engine (which was probable) or too small (not so probable), and in either case it was replaced by a larger one. At about the same time or date as the above specimen of steam engineering was common among the generality of steam engine users, there was another section of them who proceeded on much more scientific lines, leaving out of the question marine or locomotive practice. I refer to the cotton industry of Lancashire, and to those who brought it to and maintained it at the high state of perfection in which it then was. The cotton spinner then, as befitted the most important steam engine proprietor and user, set to work on better lines. When he wanted to drive his mill he knew exactly how many spindles with the necessary preparation machinery could be driven by 1 H.P., and in buying an engine it was an easy matter of calculation to find out how much horse-power to provide. It was also an easy matter to calculate how much horse-power an engine of a given size would develop, at a given steam pressure and speed, and an engine of the size so arrived at was ordered accordingly. If then the engine did not do its work well, or without breakdowns or heating, there was no question about it—it was a bad engine, and would either have to be altered or come out. But long before this the weak points of these engines had been thrashed out and eliminated, at least by engine builders of any repute, and the cotton spinner, by dealing with firms of good repute, was practically certain of getting an engine that was up to and would give the work required of it without any undue trouble. This engine, then—the Lancashire mill engine—entered the field of electric lighting almost completely prepared for the work; the only thing was, that in the early days of electric lighting it was rather too big, and there were then not many large installations requiring to be driven.

Now, as soon as it became evident that the newly-opening-out field of electric lighting was likely to require the services of a large number of small-sized steam engines, nearly every maker of them suddenly awoke to the fact that his particular make of engine was particularly suited for electric lighting work, and advertised the fact. The wish, however, was but father to the thought, and as soon as one of these engines was set to do the work that by calculation it should be equal to doing, and which also by exact calculation it was known to have to do, the crank-pin got hot. An extra large-sized lubricator was fitted to the crank-pin, and the engine was advertised as being specially designed and equipped for electric light work. But still it did not do. Why, then, did engine builders still persevere till they did produce an engine that would do the work it should do, when all the time there was the slow-speed mill engine waiting and willing to do it? I have said it was too large; so it was, but it would not have been difficult to make small copies of it, and then the thing would have been done. Well, apart from other reasons that will occur to you, there was of course the great question of cost—the slow-speed engine was too dear.

This, then, leads us to the birth of the moderate-speed engine, that is, the modern moderate speed one, and one that would really do without flinching the work that calculation showed it capable of doing, and keep on it for considerable periods of time. The thing was not so difficult after all, but it wanted doing, and like many other things of which that may be said, it took time to do. Firstly, the stroke wanted shortening; that to a certain extent had already been done; and secondly, the bearings wanted increasing. Here

* Abstract of a Paper read before the Northern Society of Electrical Engineers.

Digitized by Google

makers proceeded timidly, and it was some time before a correct proportion was arrived at. And no wonder, when we come to consider the great amount by which such bearings did require increasing. Take as an example an engine with an 8in. cylinder, or say 6 H.P. nominal, though this term is now obsolete in connection with electric lighting work. This engine now has a crank-pin as large as that used in a 16in. cylinder or 25 H.P. nominal of the slow-speed type not many years ago, or of to-day as made by many makers. The piston speed is about the same in both cases, but the cylinder ratios are as 1 : 4. True, the smaller cylinder has frequently to stand a rather higher pressure of steam than the older engine, but the difference is not enough to account for all that difference in the size of the crank-pins. What then was the cause? Why, as you will guess, the greater number of revolutions, that is the indirect cause, the more direct cause being the tendency to knock at the higher speeds and thus displace lubricant. The main bearings have not increased in the same ratio, and for one reason, viz., that owing to the speed being higher the flywheel can be much lighter and smaller.

Lubrication then also became a most important question, the extra large-sized lubricator on the crank-pin, spoken of before, had to be abandoned because it could not be filled while the engine was running, and in its place some continuous method of supplying oil was adopted. A whole crowd of wick or screw adjustment oilers has in most good engines now been replaced by a central oil box, with a pipe to each important bearing, and having a sight drop arrangement at the box so arranged that the supply can be cut off without altering the adjustment. By still more perfect means of lubrication a crank-pin or main bearing can be made to run absolutely noiselessly, even though the brasses are considerably worn. It will be known to many here that Messrs. Bellis, of Birmingham, have effected this by means of forced lubrication from a pump, the oil being distributed through holes, drilled in the crank shaft, to the various bearings. My own firm have a patent which secures the same result, at least in the case of crank-pins and eccentrics, the oil in this case being led to a centrifugal oiler and thence to a suitable cavity in the crank-pin. This cavity is formed by a flat rather narrower than the width of the crank-pin, and is opened or spread out into a long oil groove, the trailing corner of which is well rounded. The position of this cavity on the crank-pin is dependent on the following fact. If you examine the forces acting on a crank-pin in a double-acting engine you will find that there is one portion of the pin surface that is never acted on by the brasses. The cavity is formed on this portion of the crank-pin, and being kept supplied with oil, it passes over each half of the bearing in the big end of the connecting rod immediately before pressure comes on to it, the rounded shoulder facilitates the spreading of the oil and indeed acts as a swab, filling up any clearance or play with oil. When pressure then comes on either brass this oil has to be expelled, and acting as a dash pot prevents any sudden shock or knocking, and the bearing thus runs silently.

At the same time as affecting this displacement of lubricant by knocking, I may here mention the ingenious self-adjusting bolts of Mr. D. Abercrombie, by which wear is automatically taken up as it occurs and knocking avoided. In this arrangement the nut on the ordinary marine pattern bolt, instead of being locked hard, is under the control of a torsion spring, the torsional tension on which can be varied by means of a circular ratchet at the other end of the spring. Play or strip is allowed between the two halves of the bearing, and when the brasses wear, and the nut would otherwise tend to become slack, the spring rotates the nut slightly, thus following up wear as it occurs, just as one would with finger and thumb tighten a nut on some slow-moving piece when reciprocating action was causing knocking.

Another important detail that has led to the success of the modern moderate-speed engine is by no means a new one; it is only the almost universal adoption of it in this class of engine that is new, and that is the use of white metal in the bearings. I believe it is not too much to say that the fast-running engines of the present day, including marine and locomotive engines, in addition to those we are now considering, would be almost impossible without the use of white metal. It is impossible almost, and would at any rate be invidious, to attempt to say what particular make of white metal is the best for any one purpose. There are many makes on the market, and many good ones I believe, but to go no farther than the old Babbit metal, the advantages of its use over brass or bronze are many. Not only is it much less ready to take offence at any small particle of dirt that may get into a bearing and get hot, but it wears longer; and, moveover, by use puts a polish on the pins or journal of the shaft, that not only necessitates less oil being used, but must also reduce internal friction in the engine. In heavily loaded bearings, such as cross-head pins, &c., a quality must be used of sufficient hardness not to pound out.

Then we have another set or class of improvements that were necessary, and have been, or ought to have been, incorporated in the moderate or high-speed engine of to-day, and I refer to various fastenings about the engine. For example, some years ago, when the firm of which I am a member first began to make engines that we fondly hoped were perfect for electric lighting work, we had the lock-nuts of one of the connecting rod big end bolts, in a small engine, jar off whilst working. The lock-nuts were good enough for the old slower speeds, and when you could stop and tighten them if you heard the engine pounding badly through their coming loose, but they would not do for electric lighting. Nothing more serious than a stoppage (quite bad enough I admit) happened in this case, but from that date we abolished lock-nuts throughout the engine (except on main bearings), and used other and more secure devices in their stead.

Slides valves used to be secured on their spindles between lock-nuts in the old days, a doubly bad arrangement. No doubt many of you can recollect trying to tighten these at some now distant date with two keys (both too thick) and some pieces broken off the end of a file by way of packing, or with a hammer and chisel. And how the spindle used to spring when you tried to hammer against the nut on it. Apart, however, from the difficulty of tightening the lock-nuts in the valve chest of an engine, they were bad because of the small amount of surface they exposed for driving the valve. Knocking thus took place early at this part, and this tended still more to loosen the nuts. Some of you may say that a pin beyond the nuts would have prevented them coming off altogether if it would not have prevented the knocking. So it would, but pins are very often dropped into a crank pit, or on to a dirty floor and lost, or, sadder still, forgotten by an ordinary attendant, and as they do not grow anywhere about an engine room they are not always replaced, especially when, as very frequently happens, the engine is wanted to start off as soon as ready, if not sooner, and so split pins do not get us out of the difficulty, though they should still be used as an extra precaution should the device adopted fail from any cause. Here then, again, was a point to be remedied if the engine was to do its work properly. For the same reason lock-nuts on gland studs should be abolished, and a method adopted whereby the nuts can be prevented from jarring loose, and that whilst the engine is running. The same remark also applies to the nuts on the eccentric clip bolts, though these, of course, cannot be tightened up whilst the engine is running. The crosshead and its guide, too, was, in the early days, unsatisfactory. In the first place, unless the pin or gudgeon was too small, as it generally was, the cross-head was too heavy, the most frequent construction of forming the fork in the crosshead and fitting the brasses in an eye in the connecting rod, not allowing of a very satisfactory job being made of the crosshead if lightness were attempted, unless the pin was made rather short in the bearing. To obtain a wide pin and at the same time a light crosshead, the plan is now almost universally adopted of forging the cross head on the piston-rod, thus saving the heavy boss and avoiding the risk of the cotter giving out if water were met with in the cylinder, and forking the rod, by which means a wide pin and a light cross-head is obtained. It is also as well, in a crosshead of this type, to arrange it so that the pull does not come on to the cap bolts, as by this means the difficulty arising from the improperly-secured nuts is avoided, and at the same time a stronger construction, weight for weight is secured, the brasses being adjusted by means of a wedge and the cap bolts merely being utilised to keep the cap in position, the pull due to the steam being taken by the cap itself, which is lipped over on to shoulders formed on the crosshead for the purpose. The slipper also, though not susceptible to any radical change, should be amply proportioned, so that there is no danger of lubricant being forced out from between it and the slide. A word should also be said about pistons, not that there has been any very radical improvements made in them of late years, but rather that, of the types to hand, the most suitable should be chosen, and moreover, it should be carefully made.

Cast iron rings wear very well if made of good material, but, unfortunately they do not lend themselves, at least in the ordinary form, very well to use with a solid piston body, which is much to be preferred to one made with a junk ring, in an engine running at moderate or high speed. The ordinary pattern of piston, solid if over 16in. or so in diameter or made with a junk ring if less, with two cast iron rings expanded by an inch coil, answers very well for slow or very moderate speeds, but it is certainly advisable to avoid the screws necessary where a junk ring is used, and also to reduce as much as possible ring friction, which with the above construction is probably always more than necessary. The St. John steam expanded ring appears to give good results so far as I have tried it during the last two or three years, and it has the advantge that it can be made in cast iron and yet be sprung into a solid piston body even if of small size, and being steam expanded, it exerts a pressure on the cylinder walls in proportion only to the pressure of steam in the cylinder.

Another point that deserves attention is the valve. This may be either of the flat or piston type. The flat valve has the advantage of cheapness and steam tightness, but it takes more

Digitized by Google

power to drive than the piston valve, and that is a consideration where automatic expansion by means of a shaft governor is used, as it always should be. It does very well, however, with low pressures of steam, and if made with a trick port, gives good openings to the cylinder and that without excessive travel. In the low-pressure cylinder of a compound engine it is advisable to carry the spindle through the valve chest so as to afford a double bearing for it and to fit a spring between the spindle and the valve, as by this means the annoying clattering present when running non-condensing on light loads is avoided. The piston form of valve has also the advantage of giving good openings in consequence of the length of lip, which is, of course, equal to the circumference of the valves, less the bars in the liner, and I suppose no one would make one without a liner. It is also balanced from steam pressure, and is therefore easy to drive, unless it is rusted up, or working with red lead squeezed out of pipe joints as a lubricant instead of oil. Provided, however, that it is clear and well-made, it works with very little friction. As regards improvements in this important detail, I am afraid it is even yet too early to speak. Undoubtedly the best construction is a well-fitting solid valve, without packing of any sort. The liners should be most carefully bored out to attain this result, ordinary boring not being good enough unless lapped out afterwards, and this is not very advisable, as it is impossible to get out all the emery used in lapping. The valve should be ground and polished to a perfect fit, and then as long as that condition of fit lasts you have the best valve. But unfortunately that condition is not an everlasting one, and there is, therefore, a great temptation to fit some form of spring packing. The objection to spring packing is that the liner gets worn as much as the rings, and when it becomes necessary to renew the valve it is like "putting new wine into old bottles"; they do not go well together.

I am hoping, however, that good results can be secured by a valve having steam expanded rings as described for main pistons. It is to be noted that a piston valve cannot leave its seat like a slide valve, and consequently it is necessary to apply spring relief valves to a cylinder fitted with this form of valve, to allow of the exit of any sudden flush of water that may come into the cylinder, and for which purpose the ordinary drain cocks are, of course, useless.

I take it for granted that by this time no engineer makes an engine in which the joint between the frame and cylinder is a steam joint, as that means dismantling the engine should such a joint blow. As regards the necessary steam chest and cylinder cover joints, the best practice is certainly to make them metal to metal, scraped and ground together, and dispense with any more jointing material than boiled oil. I have now reviewed most of the points that have required attention at the hands of engineers in adapting the moderate speed, and still most extensively used engine to the needs of electric lighting work; I have not, however, entered into the question of governing beyond suggesting that a shaft governor should be used, altering the angular lead and throw of the eccentric so as to vary the cut-off and compression. The number of forms of shaft governor is now so great that they really require a Paper of their own to adequately deal with them. I think I ought, however, to give some reason why a shaft governor is to be preferred to one operating a throttle valve, but before doing so, I might refer to one feature of the throttle valve governor wherein it is superior to the other, and that is the case with which its speed may be altered whilst the engine is running. A speeding device for a throttle valve governor usually takes the form of a supplementary spring attached to some moving portion of the governor operating the valve. When tension is put on this spring an extra resistance is added to that restraining the opening of the governor balls, and thus more speed is required to get them out, and the engine has to run faster to do so, or *vice versâ*. Speeding gear, it is true, can be fitted to a shaft governor, but it is nothing like so simple a matter; on the other hand, the advantages of a shaft governor controlling the cut-off are many and manifest. First, the great objection to a governor belt is entirely removed, this can also be secured in a throttle valve governor, and in two ways. The governor may either be driven by a pitch chain or it may be mounted on the shaft of the engine, and its motion transmitted to the valve by means of a system of levers. The first of these two methods has not made any great headway as yet, though I believe the use of chains for driving governors is extending, especially in large, or horizontal engines, fitted with Porter governors, the great improvements made in pitch chains of late years having made this system of driving governors at least feasible. The second method is more frequently used, and especially on engines for the Admiralty, the arrangement is not, however, equal to automatic expansion by a shaft governor in results, nor indeed, if speeders are not required, in first cost. Then there is the question of economy in the use of steam. It is, I may say, almost obvious, that within certain limits it is more economical to admit high pressure steam to the cylinder, cut off as early as the load will allow, and expand down. With a steam jacketed cylinder there is perhaps no limit to the point at which early cut-off is not more economical than throttling, but as an engine rarely works for long together with a very early cut-off and the consequent great variation of temperature in the cylinder, the advantages of steam jacketing become less apparent, and they are usually dispensed with. Now, with a throttle valve and fixed eccentric, the only point at which anything like full steam pressure can act on the piston is at full load, and consequently the eccentric has to be set to give a sufficiently late cut-off to deal with the maximum load that the engine is ever likely to be called upon to do. In many cases, and more especially in electric traction work, this maximum load must be considered as all that can possibly be got out of the engine with 0·6 to 0·7 cut-off, and beyond which very little extra power is obtained for later periods of cut-off. It follows, therefore, that during the greater part of its working hours an engine so fitted must be working under conditions very unfavourable to economy so far as expansion of steam is concerned. The above remarks apply with more force the greater the steam pressure used, and at very low pressures, say 30lb. or so, there may not be much in automatic expansion after all. But nowadays such pressures as 30lb. to 40lb. are rarely met with, except in old works, and they are hardly worth considering.

Then, again, on the mere question of governing—that is close regulation of speed—the shaft governor has the advantage, and for the reason that the compression of the exhaust in the cylinder is varied at the same time that the cut-off is altered. This most important feature is well seen in comparing the indicator diagrams from an engine working under varying loads, and fitted with one or the other form of governor. Take the throttled engine first; at full load the card is all right, but at light loads, it is seen that, except the pressure is reduced almost to nothing, there is still considerable area left. It becomes necessary, therefore, to insure that the steam should be throttled to reduce the pressure sufficiently to hold the engine, and this means having the throttle valve a good fit; it must not fit too well or it will stick, and it must not be too slack or the engine will run away, and those who have not seen it would be surprised to see how very little space between the valve and its seat is sufficient to allow an empty engine to run away.

Now look at the cards from an engine fitted with a single slide (or piston) valve and a shaft governor. At full load you have a full card as before, but as the load lightens the cut-off is made earlier, and at the same time the amount of compression is increased till at no load the exhaust is compressed almost up to boiler pressure, and the diagram has very little area left; just sufficient, in fact, to keep the engine running at its proper speed. The compression so produced is, at the same time, useful in bringing the reciprocating parts to rest, and thus minimising knocking if present, and at the same time is a source of economy, and for two reasons: first, that the compression raises the temperature of the exhaust steam and thus heats the cylinder walls before the advent of the new steam; and secondly, the cylinder being open to the atmosphere or condenser for a much shorter period of time, radiation and loss of heat is prevented.

I was careful just now to say "an engine fitted with a shaft governor and a single valve," and it was necessary to do so, as there is another way of using a shaft governor, and that is with two valves. A main valve is used in this case, driven by a fixed eccentric, set to give the latest cut-off and compression required. The cut-off valve works on the back of the main valve, and its eccentric is loose on the shaft and under control of the shaft-governor, but this eccentric is merely rotated round the shaft to obtain the various points of cut-off; that is, it has angular lead only altered and not its throw. This method of governing, which has for its first disadvantage the multiplication of parts necessary to operate two valves, has also the same disadvantage as the throttling method, *i.e.*, the fixed compression; but it has also another special one of its own, and that is, if any steam is admitted at all it is of high pressure, and even it be cut off at the dead centre, the clearance will be all filled, and enough steam get in to make the engine run away. It must therefore be arranged to take practically no steam at all when running empty or lightly loaded; it must not, however, cut off steam too soon before the extreme position of the governor weights is reached, or it will hunt, and the adjustment is rather a nice one. This form is, however, very seldom now, and is not worth consideration here. The above description of the main forms of governors in use is, I am aware, a very vague and incomplete one, but the limits of this Paper do not allow of my pursuing the subject further, important as it is. It will be observed that so far the bulk of this Paper has been devoted to a consideration of the form of and manner in which improvements in the moderate speed engine has come about; and I have given that portion of the subject the chief consideration, because, as I have stated, it is still the most generally used type of engine, and the one with which I myself have chiefly had to do with. I feel, however, bound to say something on my third class of engines, viz., the high speed one. Now, just as I said at the commencement of this Paper, that *per se* slow speed is a disadvantage, so I must now say that *per se* high speed is a great advantage, and for the simple reason that direct communication with the dynamo is possible, and all other means of transmission are avoided. I need hardly remind you that

Digitized by Google

the previously-considered moderate-speed engines are also very frequently coupled direct to dynamos; and, indeed, for the matter of that, so are slow-speed engines; but whereas with a slow-speed engine the dynamo usually takes the form of a flywheel alternator, and is, therefore, very big. So the moderate-speed engine, when direct coupled either to an alternator or direct-current dynamo, requires such to be bigger and more expensive than if they were coupled to an engine running at a higher speed; and thus the important element of first cost of dynamo steps in in favour of the higher speed, but in many cases this is partially, or altogether, balanced by the less cost of the moderate-speed engine.

I will not now, any more than at the commencement, endeavour to hunt up all the advantages of high speed *versus* slow speed, but would prefer to hear what you, who have to deal with both, have to say, and why you have formed your preference. I must say this, however, that after all, the term "high speed," being a relative one, and if it is desirable to attain to speeds in the engine corresponding to those usual in the dynamos, why is it that the highest speeds to-day do not exceed 500 revolutions? It is not because dynamos cannot be made to run faster than this, because you know well that speeds from 500 revolutions in the largest to 1,000 revolutions or more in the smaller dynamos are, to say the least, quite usual.

Well, for one reason, the centrifugal strain, that is, the momentum of the moving parts, goes up as the square of the revolutions, and this imposes a limit on the speed, as bearings cannot be indefinitely increased, and then again, the high-speed engine-maker has only the same choice of materials of which to construct his engine as are to the hand of the maker of slow-speed engines. He can only be more careful in his workmanship and choice of materials, whether cast-iron, steel, or bearing metal; but if he chose, the slow-speed engine-maker could also be, and no doubt often is, equally careful. It is not very likely, therefore, that any great increase in speed, over what at present obtains, will be attained, that is in engines of the class we are considering, or where there is rubbing contact.

The high-speed engine can no doubt be made very economical, if only on account of its high speed, and the consequent higher temperature of its cylinder walls, but it is more susceptible to derangement from careless use, and if a breakdown of any part should occur, the results are more disastrous than in a slow-speed engine. Water in particular is a source of the greatest danger, and a separator is, therefore, usually fitted to this class of engine. The high-speed engine is, however, such a special piece of apparatus, and there are so few makers of them, that it is impossible to deal in any other than a general manner with them without simply describing A's or B's engine, and, therefore, also because this Paper is already sufficiently long, I cannot very well give you any historical account of the perfecting of this form of motor.

There is, however, one point to which I should like to call attention before bring this Paper to a close, and that is, that in addition to the electrical industry having created a demand for a new and improved race of engine attendants—that is, at any rate, so far as land practice is concerned—the old easy-going mill engine tenter with hardly a care to trouble him, has in central electric light stations had to give way to a man who is constantly on the watch lest anything should go wrong, and who, with others about the station, is alive to the importance of maintaining a steady and uninterrupted working of the plant under his charge. Marine engineers knew what this meant better than those in charge of stationary engines; but the advent of high speed steam and dynamo electric machinery that must be kept going, has necessitated vastly increased watchfulness and care from those in charge to what obtained only a few years ago.

On starting up a new plant, too, it is most important that the bearings should be overhauled before commencing to work, as grit and dust is nearly always present when engines are being installed, and it is almost impossible to ensure that it shall not get into the bearings. For this reason it is always advisable to keep engine and dynamos in a room quite separate from the boiler or stoke-holes, for it is quite impossible to ensure at all times that ashes and coal dust will not be blown about and get on to the engines and lead to hot bearings. The question of oil should also receive more attention than was considered necessary formerly, and filtering should be resorted to unless the makers can guarantee it free from grit. The question of oiling cylinders is in rather a curious state, some engineers of repute saying that if steam cylinders are never oiled, they do not, as it were, feel the want of it, and work very well without. For my own part, I must say, I prefer to go on using oil in them, and oil too of the best quality. Inferior cylinder oils are possibly worse than no oil at all, depositing as they do a dark sticky substance on pistons and rings, &c., and rendering the latter sometimes quite inoperative. It would be very interesting to know definitely what difference (if any) is made in the wear and internal frictional resistance of an engine working with and without oil in the cylinders. In cases where surface condensers or exhaust steam injectors are used, there is, of course, an obvious argument in favour of running without oil in the cylinder, but we have now oil separators, to prevent the feed water carrying grease over into the boilers, and something of the sort is certainly needed in cases where oil is liable to be carried into the boiler. Apart, however, from the question as to whether it is possible or not, or how far it is necessary to keep oil out of the boilers, it still remains a moot point as to whether it is better for the engine that oil should be used in the cylinders or not.

JUNGFRAU ELECTRIC RAILWAY.—INTERNATIONAL COMPETITION.

We have been requested by Herr Guyer-Zeller, of Zurich, President of the Commission of the Jungfrau Railway, to publish the conditions of an international competition for the best solution of a number of questions connected with the construction and working of an electric railway up the Jungfrau. Prizes of a total amount of £1,200 are offered. The points to which attention is called are as follows:—

I.—The Design of the Line.

(*a*) The section of the tunnel, without and with stone lining; the foundation and overhead construction, rails, rack-rail, switches and crossings.

(*b*) The system to be adopted for the electric transmission of the power; equipment of the primary stations; system of distribution of the current along the line; protection against atmospheric disturbances.

(*c*) The electric cars, with all the necessary safety devices.

(*d*) Designs for the station building and restaurant at Eigergletscher Station.

(*e*) Construction and equipment of the intermediate stations.

(*f*) Design of a *Klubhütte* shelter to take 50 persons at Mönchjoch Station.

(*g*) Elevator, about 100 metres high and 8 metres in diameter, provided with staircase, at the summit of the Jungfrau.

II.—The Construction of the Line.

(*a*) The boring of the tunnel: electric boring machines, blasting material, ventilation.

(*b*) The removal of the spoil.

(*c*) Precautionary measures for the maintenance of health and life of the workmen, patterns of movable barracks.

III.—*The Working of the Line.*

(*a*) Plans for insuring under the given conditions a continuous working of the line.

(*b*) Electric lighting of the tunnel, cars and stations.

(*c*) Electric heating of the cars and stations, precautions for the safety of passengers and working staff.

One or more of the above points may be dealt with by a competitor or several competitors collectively. Further suggestions likely to be of advantage to the Jungfrau Railway undertaking are also invited.

The scientific Commission, with the assistance of experts, will settle the award of the prizes. The results will be published. Upon the prizes being distributed the Jungfrau Railway Company will acquire the right to use the plans obtaining prizes without further compensation. The commercial copyright will, however, remain the property of the author. Rejected papers will be returned.

The following data are given:—The maximum gradient of the line is 25 per cent. The gauge is 1 metre. The sharpest curve is of 100 metres radius, and the maximum radius is 500 metres. The greatest width of car must be 2·5 metres, the greatest height 3 metres, the maximum speed 7 to 10 kilometres per hour. The water power at the disposal of the electrical plant is about 5,000 H.P., and will be taken from the river Lütschinen. The distance between the power house and the starting point of the line on the Kleine Scheidegg is about 8 kilometres, from there to the tunnel entrance it is 2½ kilometres, and the tunnel has a length of about 10 kilometres.

Competitors must illustrate their schemes by drawings or models, and must also enclose estimates of costs. The latest date for sending in schemes is August 1, 1896.

Further information may be obtained from *Bureau der Jungfraubahn, Bahnhofstrasse 10, Zurich, Switzerland*, where also general plans, the result of geological investigations and details of the water power available may be obtained.

The scientific Commission of the Jungfrau Railway will consist of Prof. Becker (Zurich), H. Brack, technical director of the North East Railway (Zurich), Prof. Golliez (Lausanne), Dr. Maurer (Zurich), Dr. L. von Salis-Guyer (Basle), Dr. Schmid (Berne), Rev. G. Strasser (Grindelwald), E. Strub, railway engineer (Interlaken), Prof. Walder-Meyer (Zurich), Prof. Weber (Zurich), Dr. Wrubel (Zurich), and President Guyer-Zeller.

THE RAWORTH HIGH SPEED STEAM ENGINE.

The Brush Electrical Engineering Company have recently placed upon the market a high-speed enclosed steam engine, which they are manufacturing under the patents of Mr. J. S. Raworth. The name "Universal" high-speed steam engine has been given to it by the makers, who have supplied us with the following particulars of its construction. It is essentially a tandem engine, for either simple, compound, triple, or quadruple expansion, according to requirements. Fig. 1 gives longitudinal and cross-sectional elevations, and shows the chief working parts. The cylinders are arranged in pairs one above the other, and the valves are placed between the cylinders. The valves are of the Corliss type, and the high-pressure valve is distinct from the low-pressure. The high-pressure steam presses on the under surface of the small upper piston, and the expanded or receiver steam presses on the upper surface of the low-pressure piston. During the down stroke, to the point of cut-off, the receiver and the high-pressure cylinder are in communication with the low-pressure cylinder. The high-pressure piston at the top of its stroke passes ports in the cylinder, whereby the pressures in the cylinder and in the receiver are equalised; but the capacity of the receiver is so arranged that the difference in pressure between the high-pressure cylinder and the receiver shall be small. The high-pressure cylinder steam on the downward stroke of the piston expands into the low-pressure cylinder until the cut-off valve closes, when the remainder is passed into the receiver, excepting a small residue retained for compression. Any water taken into the high-pressure cylinder is discharged into the low-pressure, and when the low-pressure piston arrives at the bottom of its stroke, the water is discharged through holes in the cylinder into the lower exhaust chamber. The exhaust valve is connected with the lower exhaust chamber by an external pipe. The main exhaust pipe is carried away at the lower level, and, when working non-condensing, involving an upward turn of the pipe, a large drain pipe must be taken downwards before the exhaust pipe arrives at the first upward bend.

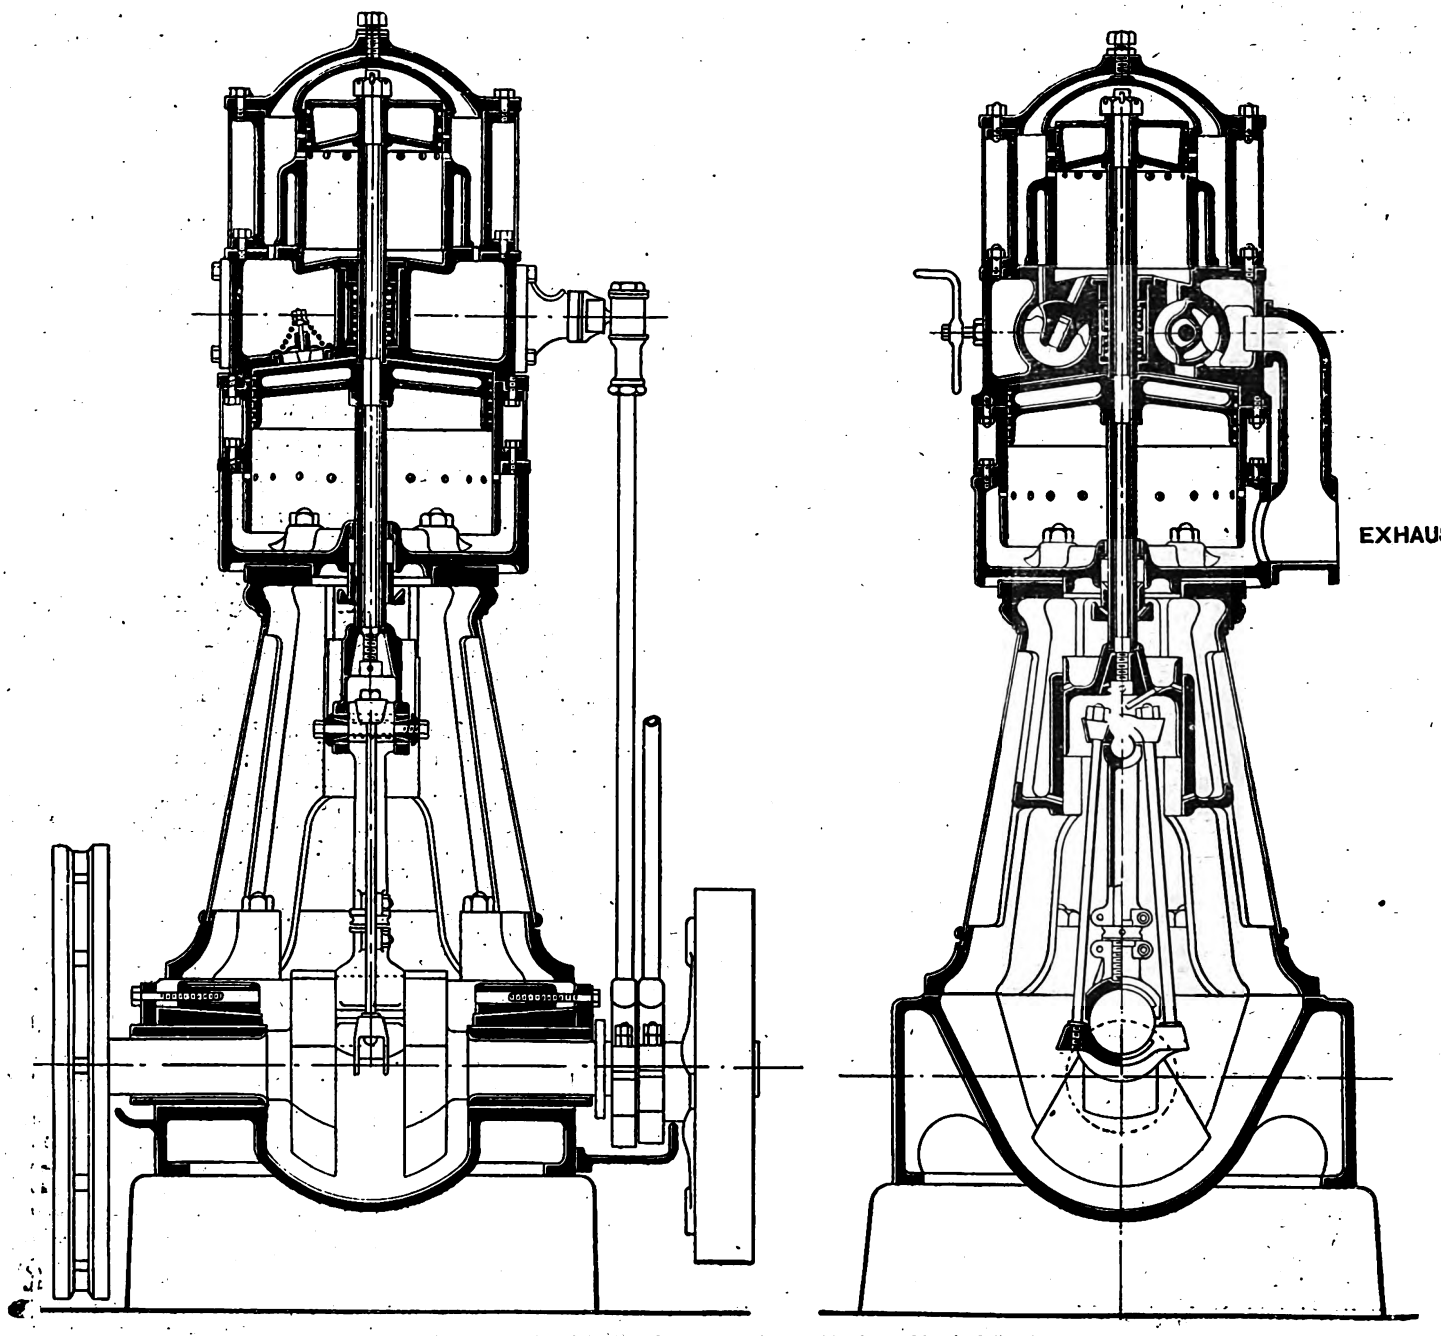

FIG. 1.—Raworth High Speed Enclosed Steam Engine. Vertical Sections.

Triple expansion engines are arranged with two pairs of cylinders and two cranks. The high-pressure and intermediate cylinders are placed in tandem over one crank, and two low-pressure cylinders are placed over the other crank. With this arrangement it is desirable to use a drain and steam trap from the intermediate receiver. Quadruple expansion engines are arranged with two pairs of cylinders and two cranks, each pair of cylinders being arranged and connected as described for the compound engine.

The cross-section of the compound form of engine on the centre line at right angles to the axis of the crank shaft (Fig. 1) shows only the port in the low-pressure valve between the high-pressure and the low-pressure cylinders. The port which communicates between the upper side of the low-pressure piston and the receiver

Digitized by Google

is behind the parts shown in section. The valves are worked by two eccentric rods acting on levers attached to the valve spindles. The high-pressure eccentric is driven by a centrifugal shaft governor, which controls the cut-off from 0 to $\frac{3}{8}$ stroke: the low-pressure eccentric is fixed on the shaft and is set to cut off at about half stroke. Indicator diagrams in Fig. 2 show the action of the valves at full load, half load and zero load.

Lubrication is entirely automatic. The crank pin is lubricated by the oil bath in the base, while the joints and bearings of the valve levers and spindles, also the piston rod, guides and cross-head are lubricated by a small double-spur-wheel pump which takes oil from the crank pit and distributes it to the various joints and bearings. The cylinders are lubricated by means of a large displacement lubricator, which holds a month's supply of oil.

In the construction of this engine its truth, *i.e.*, the perfect alignment of the cylinders, crosshead, guide, and crankpin—is obtained throughout by machine work. The crank shaft is of

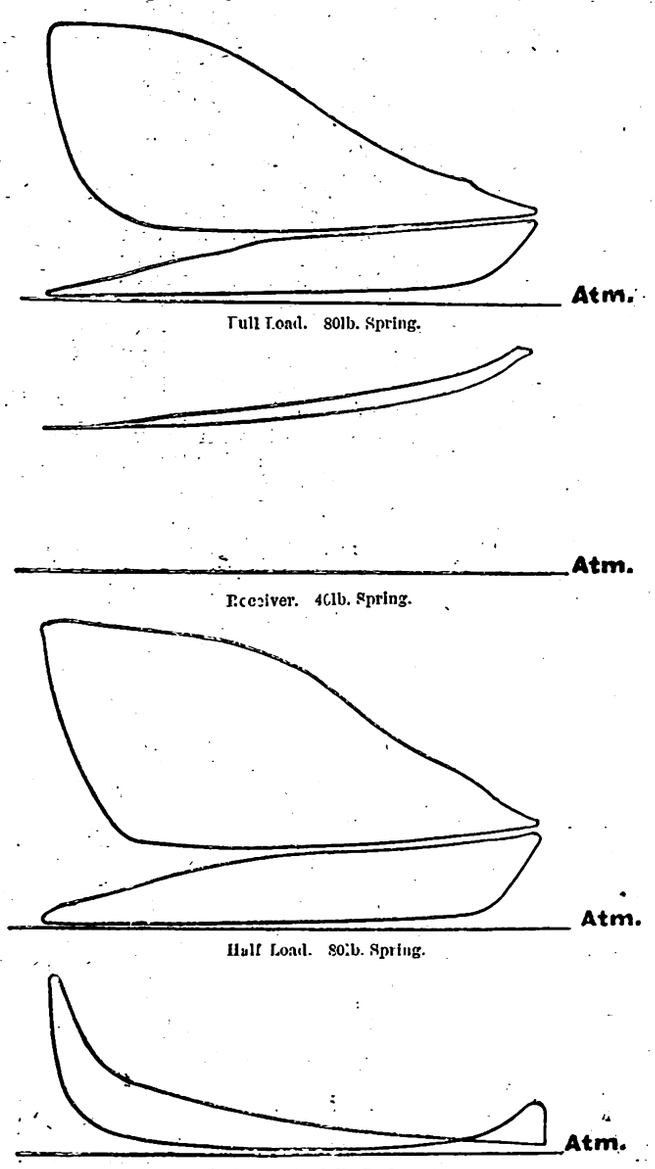

FIG. 2.—Raworth High Speed Enclosed Steam Engine. Indicator Diagrams.

Siemens-Martin steel, annealed after rough tooling, and balanced as far as practicable opposite the crank. The main bearings are fixed in solid seats in the baseplate casting, bored by a special machine which ensures absolute squareness with the centre line of the cylinders. Wedge pieces drawn up by external screws hold down the bearings. There is also an adjustment to take up end wear, should any occur.

The connecting rod is in two separate parts; an external frame transmits the pull on the up-stroke, and an internal strut takes the pressure of the down-stroke. The external frame is made of a fixed length, but the internal strut is provided with a powerful screw adjustment by which any slack can be readily taken up. This facility in taking up wear is designed to prevent knocking, and to render the running of the engine at all times quiet. When the engine is at work the adjusting screw is clamped tight, and is prevented from working loose. The cross-head pin is hollow, and is designed to be perfectly tight in work and yet quite loose for removal. This pin is a free fit in the hole in the cross-head, but the ends are bored conical and split. To fix the pin the two cone plugs are drawn up tight by the bolt, and thus expand the pin in the bearing holes. The attachment of the piston rod is such that the piston-rod can always be drawn out from above. The end of the piston-rod is screwed and fitted with a conical nut in halves. To get the rod out it is only necessary to unscrew the top nut and let the rod down a few inches, when the lower nut falls off, and the rod can then be lifted. The bottom gland is forced into position by a loose frame which will not put any cross-wind on the gland, however irregularly it may be screwed up. By being brought nearer to the outside of the engine the bolts are also made more accessible.

The high-pressure valve is of the ordinary Corliss type, and the low-pressure valve is similar, but more nearly resembles a Wheelock valve. Both patterns have been proved, by many years' experience in hundreds of other engines, to work well, with very little wear. Trip gear is not used, on account of the high speed, but the shaft governor cut-off gives even better results, as it throttles the steam at very light loads, giving thereby, according to Willans' law, the conditions of maximum efficiency. The practical results are in exact accord with the theory.

The high-pressure valve admits live steam to the high-pressure cylinder, and cuts off under the action of the automatic shaft governor. It also admits steam directly to the receiver when the

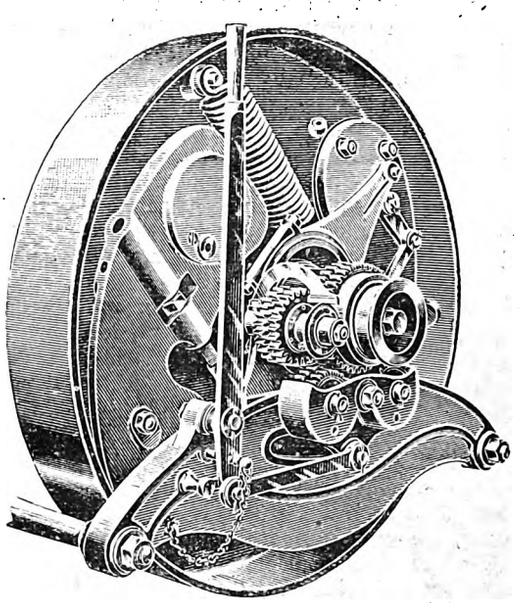

FIG. 3.—Raworth High Speed Enclosed Steam Engine. Governor and Speeder Gear.

engine is standing or running at slow speed. The receiver port is very small and narrow, and is only open in the extreme position of the valve. At full speed the governor reduces the travel of the valve, thereby shutting off the supply to the receiver.

One of the features claimed to be best in this engine is the eccentric rod joint, which is of simple construction and easy to set up. The pin is spherical, and the end of the rod is fitted with two cylindrical white-metal pads with hollow spherical faces, which grasp the pin, and are set up by the large screw cap. Excess of oil passes down hollow eccentric rods to the eccentrics, and thence to the crank chamber.

The governor (Fig. 3) is in principle an ordinary crank-shaft automatic cut-off governor; but it has many improvements in detail. It has only six parts, viz., the wheel, the banjo, two weighted arms and two springs. The springs are fitted with an adjustment which enables the user to alter the range of total variation in speed from $\frac{1}{2}$ per cent. to about 5 per cent.

Its action is at light loads to combine the effect of throttling with that of expansion. Fig. 3 shows one of Raworth's speeder gears attached to the governor, this gear enabling the speed to be varied while the engine is running.

Electric Lighting of Railway Carriages in Italy.—Accumulator-charging stations are about to be established by the authorities of the Rete Mediterranea Railways in Italy, at Milan, Rome and Turin, for the charging of the accumulators used in connection with the electric lighting of the railway carriages.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *February 28, 1896.*

Röntgen Rays.—Notwithstanding the great amount of experimenting that has been done with Röntgen rays in the numerous college laboratories of this country, but few valuable contributions to the subject have resulted. Mr. O. B. Shallenberger, of the Westinghouse Company, has succeeded in taking perhaps the best radiagraphs yet made on this side of the water. He uses Teslaic apparatus, or an arrangement giving a voltage of about 250,000 volts and an enormous frequency, the latter being obtained by means of a series of disruptive discharges in circuit. But one electrode is led to the Crookes tube, the second one being connected to a disc suspended a considerable distance above the tube and vertically over the plate holder; the latter is 6in. or 8in. below the tube. With this arrangement radiagraphs taken of the hand and of small animals have the details extremely well defined. In radiagraphs of the hand, for example, the bones and sockets have the appearance of being shaded, and seem to be rather photographs by reflected light than shadows. One of the greatest advantages of this type of apparatus is that there is little if any danger to the vacuum tube, while in many of our college laboratories the stock of such tubes was quickly exhausted through breakages on account of heated electrodes. In the investigation carried on by Mr. Shallenberger it has been found that almost equally good results are obtained with either pole connected to the tube. The best results have been obtained with an exposure of 21min. Prof. Woodward, of Harvard University, has obtained some excellent radiagraphs by means of an aluminum vacuum chamber, or ray lamp. The ray lamp consists of a spun aluminum cone, with a glass base and a glass tube for exhaustion at the apex. With this ray lamp it is reported that almost instantaneous radiagraphs have been taken. Notwithstanding the attempts that have been made to properly exhaust vacuum tubes in this country, at the college laboratories and elsewhere, it is but recently that one firm, the Western Electric Company, has been able to make tubes equal to the imported Crookes or Hittorf tubes.

Electric Elevators.—The February meeting of the American Institute of Electrical Engineers, on Wednesday, was given up to the discussion of the Paper of Mr. Frank J. Sprague on "Electric Elevators," read at the January meeting (see *The Electrician*, February 14, p. 513). While some useful data was brought out, the discussion consisted of but little more than the presentation of commercial claims. The hydraulic elevator people apparently considered that the prominence which would be given to electric elevators by the Paper threatened their business, and, therefore, this interest put forth every effort to prevent its being thereby placed at a commercial disadvantage. The question of the character of the Papers to be read before the Institute is one which has given rise to much discussion among members, and it seems little likely to receive any definite answer. The December meeting was allowed to lapse on account of the rejection of a Paper thought to be too mathematical in character, and at the January meeting the other extreme was reached by the presentation of a Paper largely commercial in its bearing. The problem as to the criteria to be applied to Papers read before professional bodies is, however, probably not one confined to this country.

Massachusetts Central Stations—From an advance report of the Board of Gas and Electric Light Commissioners of the State of Massachusetts, we learn that the profits during the last fiscal year of the 83 central stations of that State amounted to $1,280,000. After paying dividends of $487,000 interest, and charging off for depreciation and sundry items, there was a net deficit of $182,000. The year before there was a surplus on this basis of $51,000. Six of the companies did not earn expenses, and 33 others did not earn sufficient to warrant the declaration of any dividend. Of the $487,000 dividends declared, $300,000 was paid by two companies in Boston, and of the companies that paid the highest dividends almost every one was in the larger cities of the State. The smaller companies either paid no dividends or very small percentages.

CORRESPONDENCE.

ALTERNATING AND CONTINUOUS-CURRENT ARCS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Permit me to correct a slip which the reporter of the Physical Society made in abstracting very briefly the Paper communicated to the Physical Society by me and Mr. Petavel on the 28th ult. In the last sentence of the abstract it is stated that "lowering the frequency decreases the efficiency of the alternating-current arc." A reference to our Paper will show that we made no such statement. What we did say was that lowering the frequency *increases* the efficiency of the alternating-current arc. A perusal of your editorial comments on the discussion leads me to believe that you had not the advantage of having the full Paper before you in writing them. It would otherwise have been evident to you that some of the objections raised, and which you adopt, are answered by the facts in the Paper. The second part of our investigations consisted in comparing the mean spherical candle-power of two arcs, each supplied with the *same* carbons and the same power, but one in an alternating and the other in a continuous form. The alternating current arcs were always formed with 15 amperes. *Important* variables were not left to take care of themselves. It forms no valid criticism to suggest that, having definitely limited the conditions of the problem for certain reasons, we ought to have done something entirely different. The question of the existence or non-existence of a carbon with the port-wine like character of self-improvement under disuse has no bearing whatever on the question at issue. The comparison of two incandescent lamps, irrespective of voltage and supplied with equal power in the two forms, is quite misleading, seeing that the question of "life" must enter into any useful comparison of incandescent lamps, and there is no such question in the case of the arcs. That which remains to be done is to extend our observations to the case of different currents. That is, to compare the mean spherical candle power of alternating-current arcs taking the same mean power, but formed with different currents, and ascertain whether in selecting 15 amperes we have in any cases taken a current which is not that which for the selected wattage gives the greatest mean spherical candle-power. Whatever may be the result, it is perfectly clear that the alternating-current arc has a long leeway to make up before it can rival its continuous-current brother, even if aided by a carbon which secretly and specially prepares itself for alternating-current work.—Yours, &c.,

J. A. FLEMING.

X-RAYS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Dr. McKay, of the Packer Institute, Brooklyn, Me. tested my idea, termed a scheme in the *Electrical Engineer* of New York, as to the possibility of exposing upon a fluorescent screen the shadows of invisible objects in motion. We saw, in what is conveniently termed a kinetoskotoscope, the motion of the bones of the fingers when bent backward and forward, the shadow of the rest of the finger being faint. The result was so successful that I noticed a curious feature which was not known to me before, and that is that the bones appear in a side view to be at the back of the finger, and very thin measured from the back to the front. There is a reason for this, I suppose, in that the inner side of the finger should be more like a cushion, so as to be better able to handle objects. An experiment was also performed, consisting in opening and closing a pair of pincers which were absolutely invisible to the eye; but the shadow of the moving parts was clearly visible upon the screen. A chain was shaken back and forth, and the separate links moving relatively to each other were clearly visible. These experiments would prove that with the present condition of the X-rays the skeleton of a fish could be seen to move backward and forward in the act of swimming, as well as the skeletons of all small objects while in motion and performing the functions of life. I think that some of the best objects to be looked at while in motion would be, for

Digitized by Google

instance, a bird, through which the rays would so easily pass except as to the skeleton. All youthful forms of life could be examined, very probably, by this means, and the motions exhibited.

I have for two or three weeks been trying different kinds of experiments, &c., and I find that certain precautions are necessary in order to obtain the best results. In the first place, it is necessary, very probably, to show just how I made my fluorescent screen, because I find that others have tried to make it by crystallising the chemical barium-platino-cyanide from a solution upon a sheet of paper. Others merely pressed the crystals upon a surface like filter paper. Such screens are of little value, especially as the substance then fluoreses blue, which is nearly invisible, and only so in spots. By the following means, the results are so excellent and the screen is so luminous that the shadows are clearer than in the X-ray photographs. The cyanide should be powdered to the finest dust possible. Then some of the clearest colourless varnish should be put upon a piece of tracing cloth, because the same is so strong, and so transparent to the fluorescent light which is produced. The powder may now be mixed very thoroughly and intimately with the varnish, so as to make a homogeneous mass, in quantity sufficient to spread over the cloth to a thickness of about one-eighth of an inch. This is mentioned because experimenters are likely to make the layer too thin. The reason for powdering the material is to produce a maximum amount of reflecting surface. The object of the varnish is to hold it together and yet permit the reflected rays of fluorescent light to become visible. The varnish should then be dried, but not necessarily perfectly dried. These directions should be followed very closely for good results. The end of the tube which is directed towards the Crookes' tube, and which contains the screen, should be covered with photographer's black paper used for wrapping up sensitive plates. Either side of the screen may be directed towards the Crookes' tube. A very important precaution is to perform the experiments in a rather dark room. It may be light enough to be able to see objects, but if the room is very light the eyes are not used to darkness, and therefore the experiments are not satisfactory, but if the room is quite dark the screen in the closed tube appears, immediately upon putting the eye to the hole in the tube, to be perfectly luminous. It will be more luminous under these precautions than luminous paint which has been held in the sunlight and brought into a dark room, and yet if performed where the eyes are exposed to the daylight the experiments are not so satisfactory. Another precaution is to have the electrical apparatus so arranged that the phosphorescent light from the Crookes' tube is steady, which may be done, of course, by means of Leyden jars or other condensers.

My idea of this new use for the X-rays was conceived and attested on February 1, 1896.—Yours, &c.,

EDWARD P. THOMPSON. M.E.

5, Beckman-street, New York, February 26th.

WATER POWER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Murray's report to the Worcester Corporation is certainly instructive, but I think your remarks thereon are calculated to unnecessarily alarm those who may be thinking of applying water-power to electric lighting. That great care must be taken to calculate the amount of power available at the minimum flow is quite certain, and it must also be considered how far the coal saving will warrant the double capital expenditure, and the more so as hydraulic works are usually very costly, though the maintenance should be small. At the same time it is hardly fair to consider only one year. Although water has proved insufficient last season, there may be much more than enough for the day load in the coming season. Last year was exceptionally bad; a dry summer following an exceptionally dry winter. Some system of storage is no doubt desirable, and it can be carried out at a reasonable cost in hilly country by the system of hydraulic storage of power to the study of which I have devoted a considerable amount of time, and have concluded generally that where the nature of the ground admits of a reservoir being constructed not more than one mile from the generating station, and where the reservoir site is not less than 200ft. above the site of the generating station, then this system will pay, if coal costs not less than 18s. per ton and is of fair quality. I am, of course, assuming that the pipe line is in duplicate, and all materials and construction of the best. I think that this system has not been sufficiently considered in this country.—Yours, &c.,

GEO. T. PARDOE.

81, Harrow-road, W., March 9, 1896.

LEGAL INTELLIGENCE.

Fowler v. The Chelsea Electricity Supply Company and Sandon v. same.

In the Chancery Division on Friday Mr. Justice North again heard these actions. The plaintiffs are the landlord and some tenants of residential flats in Cadogan-gardens. They complained that the works of the defendant Company have caused annoyance and nuisance to them, and his Lordship granted a restraining injunction suspending its operation for a certain period. The defendants now asked for suspension for a further period.

Mr. WARMINGTON, Q.C., for the plaintiff Sandon, said his client was unable to get an inspection by electrical experts.

His LORDSHIP: Did I not give the plaintiffs some option to have some inspection.

Mr. WARMINGTON: Yes; and we are entitled under the order to inspect with an expert, but defendants claim the right to object, and that the matter should come before your Lordship to say whether the person whom we desire should inspect is a proper person or whether their objection is a good one. No definite objection is taken, but defendants think he is not a fit and proper person.

Mr. SMITH, for the defendant Company: We say that he is connected with a rival company, and that it is undesirable that he should be appointed.

His LORDSHIP said he thought he had given the plaintiffs the option to have some inspection by experts, and that if there was any difficulty he should appoint some person himself.

Mr. SMITH said the terms of the order were that the plaintiffs were at liberty to inspect by persons agreed upon by the plaintiffs and defendants, and in case of difference by some person appointed by the Judge. The defendants had suggested six persons—all persons of eminence—to all of whom the plaintiffs objected. The defendants were now perfectly willing that any independent person whom his Lordship should name should go and inspect the premises.

His LORDSHIP said he really did not appreciate the difficulty, as there must be plenty of persons competent in London to whom no objection could be made.

Mr. SMITH said that Mr. Birstall had already been on behalf of the plaintiffs, and he might go again.

Mr. WARMINGTON: Mr. Birstall is a surveyor; we want an electrical expert to go there. If the matter was before your Lordship for a quarter-of-an-hour, if a particular name was objected to, we could name another, and then we could get an order.

It was finally agreed that the plaintiffs should furnish a list of three or four persons, and the defendants would state their objections, if any, to one or other of the persons. The case to be heard on Monday.

Clarke v. Julius Sax & Co., Ltd.

In the Chancery Division on Friday Mr. SWINFEN EADY, Q.C., stated before Mr. Justice North that he had a motion to restrain the infringement of a registered design for an electric lamp of a particular shape. It was in respect of the same design as was before the Court the other day (see *The Electrician*, Feb. 14, p. 525). On that occasion he moved for an injunction to restrain the infringement of the registered design, and there was a cross motion to take the design off the register. His Lordship then refused both motions, and the result was that the registration of plaintiff's design was upheld, and it was held that the defendant had not infringed plaintiff's registered design. Now what the defendant had done was to exactly copy plaintiff's design.

Mr. VERNON SMITH, on behalf of the defendant, interposing, said he disputed that. His case was that there were substantial differences between the defendant's lamp and the plaintiff's.

Motion ordered to stand over for a week.

Charging for Electric Current.

Mr. Justice Romer, in the Chancery Division, on Monday last, had before him a summons (for leave to commence an action) in the matter of the House and Land Investment Trust (Limited).

Mr. BUCKLEY, Q.C., said that the Trust were the owners of property in Whitehall-court, on the Thames Embankment, and the applicants were an electric lighting company which supplied the owners of the property with electric current. The question in dispute was as to how the Trust had to pay the company for the electric light, and the question arose under a contract of April 19, 1888. In April, 1888, the Whitehall Electric Supply Company, who were the predecessors in title of the Metropolitan Electric Supply Company (Limited), the present applicants, entered into an agreement with the Trust to supply them with electricity at a fixed

Digitized by Google

charge per lamp, not exceeding the lowest price at which the Company should at any time, or during the lease—which was for 90½ years—charge for supplying electricity to any other person or company. The present claim was for £3,630. 5s. 8d. As a general rule the Company supplied current by meter, but they also had certain lamp contracts. He submitted that these lamp contracts had nothing to do with the matter, and that the question was which was the lowest charge per unit at which the applicant Company had supplied electricity to other consumers.

Mr. BRAMWELL DAVIS, Q.C., on behalf of the liquidators of the trust, submitted that they were entitled to take into account these lamp contracts, which would have the effect of very much reducing the sum due to the applicants.

His LORDSHIP said that it was agreed between the parties that the contract could not be carried out according to its strict letter; that as between the parties the arrangement was to supply electricity at per unit, and that the basis of the account should be the lowest rate per unit which the Company were supplying other consumers at, and he so decided. With regard to the rendering of accounts he thought that three months was a reasonable time, and that the charge should be per three months at the lowest rate which the Company charged per unit, and that should apply to the past as well as the future.

The exact figures due to the applicants were left to be worked out.

Jackson v. Coventry Electrical Engineering Company (Ltd.).

This case came before Mr, Justice North in the Chancery Division on Tuesday last, on a motion in a debenture-holder's action for the appointment of a receiver and manager of the assets of the Company. The Company consented to the motion. The reason for the application was that there were actions against the Company in which there were summonses for judgment which would be heard the following day. The Company had no defence, and judgment would then be signed and execution put in at once on the assets of the Company. The Company asked for the appointment of Mr. Pearson. The Court appointed Mr. Pearson as receiver and manager to act at once, his security to be completed forthwith.

TRADE NOTES AND NOTICES.

[Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.]

SPECIAL NOTICE—The 1896 (fourteenth annual) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is NOW READY. The published price of the Directory and Handbook is 7s. 6d., post free 8s. 3d., abroad 9s. The book is greatly enlarged, is quite up-to-date, and includes the new Board of Trade Regulations issued February 6th.

NEW BOOKS AND EDITIONS.

The following New Books and Editions can be obtained of the Booksellers or direct from the Publishing Offices:—

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett *(now ready)*. Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"THE WORK OF HERTZ."—By Dr. O. J. Lodge, with many original illustrations, price 2s. 6d. nett, is now ready.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

"ELECTRIC MOTIVE POWER."—A new work, by Mr. Albion T. Snell with this title, is now ready, containing the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d. post free (abroad 11s.).

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by Messrs. W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—By Mr. F. Marten Weymouth is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

'THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.), Prospectus on application.

"PRACTICAL NOTES FOR ELECTRICAL STUDENTS."—By Messrs. A. E. Kennelly and H. D. Wilkinson, price 6s. 6d., post free.

"THE ART OF ELECTROLYTIC SEPARATION OF METALS."—A second issue Dr. Gore's book is now ready, price 10s. 6d. post free.

"ARMATURE WINDINGS OF ELECTRIC MACHINES."—By H. F. Parshall and H. M. Hobart. This work has been compiled from Notes made by Mr. Parshall in his capacity as chief Designing Engineer of the Edison and General Electric Companies of America, and is intended to serve as a working treatise on dynamo design. Large 4to, 370 pages, 140 full-page illustrations and 65 full-page tables. 30s., post free.

TENDERS INVITED.—The Corporation of Bradford invite tenders for batteries, surface condensing plant, cables, travelling crane and steam and exhaust pipes. Forms of tender and specifications may be obtained from the Electricity Office, and tenders, addressed to the Chairman of the Gas and Electricity Committee, must be delivered at the office of the Town Clerk (Mr. W. T. McGowen), Town Hall, Bradford, by the 26th inst. Further particulars appear in our advertisement columns.

——— The Edinburgh Corporation require tenders for the wiring of the City Chambers. Specifications, &c., can be obtained at the office of the resident electrical engineer, 5, Dewar-place, Edinburgh, and tenders must be sent in to the Town Clerk, Mr. Thomas Hunter, W.S, not later than 10 a.m., on the 28th inst. Further particulars will be found in our advertisement columns.

——— The Edinburgh Municipal and Police Departments require tenders for a large variety of articles, including cast-iron lamp-posts and lamp-bases, lamp globes and electric lighting materials for the Powderhall destructor.

——— The Electric Light Committee of the Bedford Corporation invite tenders for the supply and erection of one 240 B.H.P. double-acting compound enclosed engine, and one 150-unit alternator with stationary armature. Tenders must be sent in to the Clerk to the Urban Sanitary Authority (Mr. T. S. Porter) by April 4th. Further particulars are given in our advertisement columns.

——— Estimates are required by the Guardians of the Kingston Union for providing electrical communication between the workhouse premises and the headquarters of the Kingston and Surbiton Fire Brigade; also for telephonic communication between the workhouse, police station, fire station, union offices, medical officer, &c. Tenders have to be in not later than March 21st, to Mr. James Edgell, Union Offices, Portsmouth-road, Kingston-on-Thames. Some additional information is given in our advertisement columns.

——— The Municipal Authorities of Prague invite tenders for the erection and equipment of a municipal electricity generating station, for electric lighting, power and tramway traction purposes. Tenders to the Stadtrath, Prague, Austria, by June 1st.

——— The Altona Direction of the Prussian State Railways require tenders for the supply of 93,000 arc lamp carbons and 1,600 incandescent lamps. Tenders to the Königliche Eisenbahn Direction, Central Bureau (Verwaltungs-Gebäude), Altona, by the 20th inst.

——— The Wallasey District Council invite tenders for the supply of electric light machinery and apparatus. Tenders in to the Clerk, Public Offices, Egremont, Cheshire, by Monday, April 6th.

——— The French Telegraphs Department require tenders for a multiple switchboard for the Exchange in the Rue Chaudron, Paris. Tenders have to be in by the 17th, to the Direction Générale des Postes et des Telegraphes, 183, Rue de Grenelle, Paris.

——— The Visitors' Committee of the Lancaster County Lunatic Asylum invite tenders for the supply of electrical sundries, steam fittings, belting, india-rubber goods, &c., for the twelve months ending April 5, 1897. Tenders to the Chairman of the Committee by 20th inst.

TENDERS ACCEPTED.—The Electric Lighting Committee of the Belfast Corporation have accepted the tender of Messrs. Kerr, Stuart and Co. for the supply and erection of a compressed air engine starter for their electricity works.

——— The tender of the Keighly Electrical Engineering Company has been accepted by the Keighley Town Council for fitting up telephones at the Hospital buildings.

——— The tender of Messrs. John Brown and Co., of Sheffield, has been accepted by the Bradford Town Council for supplying and fixing two steam boilers at the Valley-road electricity works for the sum of £3,000.

——— The Baths and Washhouses Committee of the Portsmouth Corporation has decided to accept the tender of Mr. Grossmith for wiring the Public Baths for the electric light.

——— The Corporation of Durban has accepted the tenders of Messrs. Macfarlane and Co. for the supply of 60 arc lamp columns and of Messrs. D. Y. Stewart and Co. for six miles of 3in. and 4in. cast-iron electric mains for their electric light works.

——— The Buckingham Town Council have renewed the contract for the electric lighting of a portion of the town by Messrs. Gillies and Hornidge. The terms are similar to those of last year.

——— The tender of Mr. J. Jarvis has been accepted by the Tunbridge Wells Town Council for the extension of the electricity supply station buildings for £1,356.

Digitized by Google

TENDERS RECEIVED.—The following tenders have been received for wiring and fitting up for the electric light the new St. Marylebone Public Baths and Washhouse :—

F. A. Donnison and Co.	£2,050	0	0
Frank Suter and Co.	1,950	5	4
Harry South	1,950	0	0
Roger Dawson (Limited)	1,681	3	7
A. Emanuel and Sons (Limited)	1,666	0	0
Strode and Co.	1,633	10	5
L. Alwyn	1,422	0	0

APPOINTMENT.—The Plymouth Town Council have appointed Mr. J. H. Rider borough electrical engineer, at a salary of £300 per annum. There were 40 applicants for the position, but this number was reduced to five by the Electric Lighting Committee. Mr. Rider, who was born at Bristol in 1864, was apprenticed to Messrs. Paterson and Cooper in 1883. In 1887 he was engaged as an electrical engineer by Messrs. Blakey, Emmott and Co., and was appointed borough electrical engineer of Bolton in 1893, which position he has held to the present time.

——— It has been unanimously decided by the Electric Lighting Committee of the Edinburgh Town Council to recommend the appointment of Prof. A. B. W. Kennedy to the post of permanent consulting electrical engineer to the Corporation at a remuneration of £200 per annum. Prof. Kennedy will advise the Corporation on all points in connection with its electric supply system. Seventy applications have been received for the post of resident electrical engineer in succession to Mr. E. W. Monkhouse, which have been reduced to six, and these are under consideration by Prof. Kennedy, who will finally recommend the most suitable applicant.

TRUST DEED.—A trust deed has been executed by Mr. P. B. Steele, trading as an electrical engineer under the style of P. B. Steele and Co., 43, Commercial-street, Dundee. Mr. J. Mess, C.A., and Messrs. Johnstone and Kilgour are acting as agents.

LIQUIDATION.—Creditors of Froggatt's Electric Lighting Company (Limited) are requested to send in particulars of their claims to the liquidator (Mr. W. P. Eldrid), 11, Old Jewry Chambers, E.C., on or before the 23rd inst.

——— A meeting is to be held at 7, North-street, Sheffield, on April 7th, at 2 p.m., for the purpose of receiving an account of the winding-up of F. Marten Hale and Co. (Limited), telegraph apparatus manufacturers.

BANKRUPTCY. — A receiving order has been made against W. Northcote and Co., described as now or late of New Cross-road, London, S.E., inventors and electricians.

——— The public examination of Charles Frederick Fox, described as an "electrical engineer," Halifax, took place at the County Court on Monday last. The liabilities amounted to £544; assets, £349. The debtor stated that up to November last he was a tobacconist. He had commenced business in 1893 with a capital of £30, and he did fairly well out of it; but as he did not like close confinement in a shop he started as an electrical engineer! He had lost over £100 by a contract for electrical work at Rishworth. Examination closed.

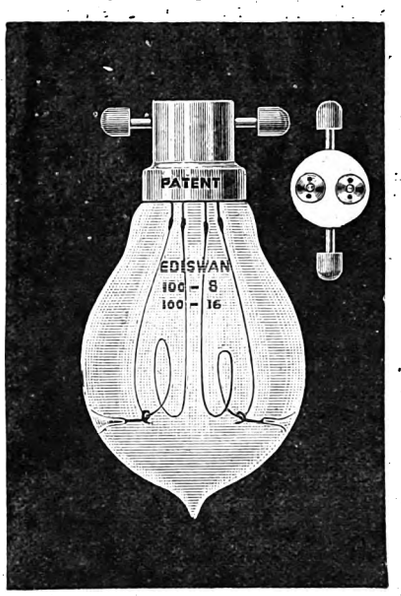
PRESSURE REGULATORS.—We are informed that Messrs. W. H Bailey and Co. (Limited), of Salford, Manchester, have been appointed by the Foster Engineering Company, of Newark, N.J., U.S.A., licensed manufacturers for Great Britain of the well-known Foster pressure regulators.

MACHINERY AND APPARATUS FOR DISPOSAL.—A quantity of first-class engines, boilers, machines, and telegraph and telephone stores are advertised for disposal in this issue, for which offers are invited by "Kent."

LESSING CARBONS.—Dr. Lessing has recently invented special machinery for manufacturing carbons for electrolysis, and at extensive works, lately erected, plates are manufactured up to 60in. in length and tubes of 55in. of 6in. diameter. The plates are described as of exceptional hardness and conductivity, and have been adopted by many manufacturers engaged in electric furnace and heavy electrolytic work. The agents in this country are Messrs. Krupka and Jacoby, 15, Queen-street, Cheapside, E.C., whose catalogue (Section 1), giving prices and particulars of arc lamp carbons, battery blocks, agglomerate blocks, &c., is now ready.

LAMPHOLDER SWITCH.—Munro's Electrical Manufacturing Company (Limited) send us particulars of a new lampholder switch called the "Empress." Make and break contact is effected by means of one of the plungers used in the ordinary lampholder, which by a simple arrangement is made to turn each time it makes or breaks, thus ensuring a good rubbing action. The working parts of the switch are entirely enclosed in the porcelain cover, and are not liable to damage when being wired, the wires passing through two separate holes entirely apart from the movement. Half the contact part of the switch is renewed each time the lamp is renewed. This form of lampholder switch can be used on a light ornamental fitting where the ordinary lampholder switch would look out of place.

ELECTRIC LAMPS AND ELECTRIC LAMP SWITCHES.—The illustration herewith shows a new design of lamp switch recently introduced by the Edison and Swan Company for regulating incandescent lamps. As will be seen, the movement consists of a sliding bar which puts the switch into action. The switch is used with a lamp (also comparatively new) supplied with two filament, one of 8 c.p. and one of 16 c.p. By means of the switch this lamp can be used as an 8 c.p., 16 c.p., or 24 c.p. lamp, or can be switched off entirely. The switch in the illustration is fixed in the cap of the lamp, but it is adaptable to any incandescent installation without alteration to either fitting or holder. The lamp and switch have obvious advan-



tages, and in working the switching arrangement is extremely simple. It will be seen that all necessary care has been taken to prevent the filaments approaching each other.

CATALOGUE.—A pamphlet of handy size has been brought out by Messrs. Mosses and Mitchell, setting forth the merits and prices of vulcanised fibre. The two qualities of this material, "hard" and "flexible," are used for a great number of purposes in machine construction and the engineering arts. Messrs. Mosses and Mitchell not only supply the vulcanised fibre in sheets, rods, &c., for working up, but they also undertake the manufacture of it in any practicable finished shape. This material has now been upon the market for 20 years.

EXPORTS OF TELEGRAPH WIRE AND APPARATUS.—The value of the exports of telegraphic wire and apparatus during the past month amounted to £109,840. The figures for the preceding month and the corresponding month of last year were £57,224 and £9,411 respectively. The value of the exports for the months of January and February amounted to £167,064, against £44,604 in the corresponding period of 1895.

THE "JOURNAL."—Part 120 of the *Journal* of the Institution of Electrical Engineers is now ready, price 2s. 6d., and can be obtained of the publishers, Messrs. E. and F. N. Spon, 125, Strand, W.C. This issue contains the inaugural address of Dr. John Hopkinson, and the first part of the discussion on the wiring papers recently read before the Institution, a Paper by Mr. G. W. D. Ricks on "Electricity Supply Meters," a communication by Mr. Desmond G. FitzGerald, and a classified list of articles on electricity and magnetism appearing in the principal technical journals during the month.

THE "ENGINEERING MAGAZINE."—The March issue of this excellent magazine contains a number of interesting articles. The subjects dealt with cover a wide range, and the illustrations and plates are of the usual high character. The subjects dealt with include—"The Money Question and Constructive Enterprise," by John R. Dunlap (Editor); "The Scotch System of Branch Banks," by J. Selwin Tait; "Prof. Röntgen's Discovery of a New Radiance," by Dr. M. I. Pupin; "The Railroad Facilities of Suburban New York," by Foster Crowell; "Standpipes for Fire Protection and Street Flushing," by L. L. Tribus; "Artistic Engine-room Interiors," by E. T. Adams; "Lighting Residences by Electricity," by A. Noll; "The Architecture of Modern Bank Buildings," by R. W. Gibson; "Prospecting with the Diamond Drill," by J. Parke Channing, and "Practical Assaying at Mines and Works," by H. Van F. Furman. The usual exhaustive review of the World's Technical Press is also given. This number, as well as all the back numbers, may be obtained at the offices of the European edition, 1, 2 and 3, Salisbury-court, Fleet-street, London, E.C.

Digitized by Google

THE FAR EAST.—Under the title of "Future Trade in the Far East," Messrs. Whittaker and Co. have in the press a work by C. C. Wakefield, F.R.G.S., who has had special opportunities for obtaining information from personal observation. The book will deal solely with commercial matters, is fully illustrated, and will contain a new and important map showing the latest developments in the trade routes, particular attention being given to the Trans-Siberian railway now in progress.

PRICE LISTS.—Messrs. Johnson and Phillips forward an additional page, forming part of their cable list No. 6, giving particulars and prices of vulcanised rubber-covered cables and wires (up to 19/18), taped only; also a new sheet of prices and particulars of Prof. Perry's patent electricity supply meters for continuous current, of which Messrs. Johnson and Phillips are the sole manufacturers.

"CASSIER'S MAGAZINE."—The contents of the March number of this magazine include "The Development of Electric Power Stations," "Protection of Electrical Apparatus against Lightning," "Some Recent Departures in Steam Engine Piston Construction," "Modern Shipbuilding Tools," "The Evolution of the Fittest Education," "New Power Developments at Niagara Falls," and "The Expert Engineer." The frontispiece is a portrait of Lord Armstrong, C.B.

ASHTON-UNDER-LYNE.—The Town Council have decided to consent to the application of the promoters of the Oldham, Ashton-under-Lyne, Hyde and District Electric Tramways, for a Provisional Order authorising the incorporation of a company, and the construction and maintenance of tramways, as set out in the Order.

BRADFORD.—At the meeting of the Town Council on Tuesday the minutes of the Gas and Electricity Committee contained reports upon negotiations with the Bradford Guardians as to lighting the whole of the workhouse buildings by electricity. The Committee also recommended that the electrical engineer be empowered to proceed with the necessary alterations at the Bolton-road electricity station for the purpose of adapting the works to the increased pressure caused by the change from the two to the three-wire system, and that the Committee be authorised to invite tenders for plant for the new electricity works and to extend the area of the Corporation's electrical supply. Mr. W. C. Dixon, the chairman of the Committee, moved the confirmation of the minutes, and said that the Electricity Department was making more satisfactory progress than was at first anticipated. The establishment of the three-wire system was rapidly approaching completion, and the greater part of the Borough, if not all of it, would shortly be put upon the 230-volt basis. In 1895 the Committee had sold 373,372 units of current, against 307,977 in 1894, an increase of 65,395 units, and the demand was still increasing. The Committee had at the present station a total H.P. of 2,210, and this power was often taxed to its utmost capacity. After paying interest and sinking fund charges and allowing for depreciation, there was a profit on the past year's working of £1,792. 19s. 1d,, against £918. 10s. 5d, in 1894, an increase of £874. 8s. 8d. After a brief discussion the minutes were adopted.

BRIDGEND.—Mr. J. C. Howell has offered to take over the Council's Provisional Electric Lighting Order, and to put down an installation for public and private lighting. The matter is to be considered at a special meeting of the Council on Monday next.

BRIGHTON.—At the last meeting of the Town Council the Lighting Committee reported that they had decided to erect 15 arc lamps in Upper St. James's-street,, St. George's-road and Chesham-road, and 15 in Lewes-road and Richmond-terrace. The Committee have also decided to extend the electric light mains to Edburton-road at a cost of £165. The Town Clerk has been instructed to appeal against the assessment of the electricity works. The accounts of the department for the year ended December 31, 1895, were submitted. The total expenditure amounted to £9,561. 0s. 8d., and the revenue (including £1. 10s. 3d. from last year) to £18,575. 3s. 8d., a gross profit of £9,014. 3s. The net revenue account showed that £1,404. 1s. 9d. had been applied to local rates and £3,000 paid to reserve fund, and, after payment of interest and sinking fund appropriations, a balance of £1,150 was carried forward. The Committee also resolved that the sum of £2,000 be transferred to the district fund account. In moving the adoption of the Committee's report, Councillor Stafford stated that the net profit for the year amounted to £1,150, but he wished it to be understood that the Council must add to that sum £4,148 paid over to the sinking fund. That left, after paying interest on money borrowed, a net profit of £5,298. He had anticipated that the profit for 1895 would not be anything like it was in 1894, owing to the lowering of the price of current. The policy of the Committee had been to make the light available for the masses, and their efforts had been successful. The receipts from private customers for 1895 were £16,177, and for street lighting only £860. They were not depending on trade lighting alone, although that would become a great acquisition during the present year. The total amount paid over to the sinking fund since the commencement of the supply was £9,330. They were aware that this was a purchasing fund, and at the end of a certain time the whole business would be purchased. The Committee were determined to pursue this policy so long as the Council would support them. He was able to state that up to that day the increase in the applications for lighting since the beginning of the present year was nearly 50 per cent., an increase nearly double that of any previous year. That showed that the policy of the Committee was a right one. The average number of units sold was 7½ per inhabitant, which was largely in excess of any other town. They had 53,000 lamps connected to their mains, but this did not include 600 lamps applied for at their last meeting, so that they were progressing by leaps and bounds. After a short debate, the report was adopted unanimously.

BURNLEY.—From the annual statement of the Finance Committee, which has just been presented to the Town Council, it would appear that the Council's electric lighting works are making excellent progress. The Committee estimate that the receipts from the department will realise £1,415 more than last year.

BURSLEM.—The Town Council have decided, on the recommendation of the Tramways Committee, not to oppose the Bill of the Potteries Extension Tramways Company. At the last meeting of the Council the Corporate seal was affixed to the amended agreement with the Company, and to an agreement with the North Staffordshire Tramways Company extending the power of the Council to purchase the Company's undertaking to 21 years from August 1st next.

CARDIFF.—All the requisite material was at hand at the last meeting of the Corporation for another petty squabble on the condition of the machinery at the electrical works, but matters were smoothed down by mutual concessions, and the minutes of the Committee finally agreed to. In the course of the discussion Mr. Carey, the Chairman of the Committee, stated that the Committee had made a great mistake in engaging four fitters at two guineas a week each, instead of three engine drivers and one practical fitter. The result of the Committee's appointment had been that each man had considered himself the equal of the other, and had made an independent report as to the condition of the machinery. Mr. Hallett, one of the most experienced engineers in the town, had now made a report which had been embodied in the minutes of the Committee.

CHELSEA (LONDON).—At the last meeting of the Vestry, the surveyor presented a report on the application of the Chelsea Electricity Supply Company for sanction to erect a generating station in Alpha-place. The report recommended that exception be taken to a portion of the scheme, as the Company proposed to erect a shaft lower than 20ft. from the centre of the roadway. It was decided to ask the County Council to withdraw its consent to this part of the application.

CHESTER.—At the meeting of the Town Council on Tuesday, the Mayor (Chairman of the Electric Lighting Committee) said that they were somewhat startled at the figure of the lowest tender for the erection of the buildings for the electric lighting machinery; but their consulting engineer, Prof. A. B. W. Kennedy, had advised them that it would be false economy to spend only £3,000 on the buildings. The building they now proposed to put up would be sufficient to triplicate the supply of electric current throughout the town, and would be sufficient for many years to come. They were advised that with an expenditure of about £5,000 more on plant also, they would be enabled to utilise the full output of the new building. The estimate for the machinery and the dynamos had also been increased, on the recommendation of Prof. Kennedy, by about £1,400, making the total amount for the machinery and plant about £15,600, against £14,200, the sum originally suggested. This increase was caused by the addition to the estimate of the arc lights for the streets, which would be a decided benefit. The total amount for the electric lighting scheme would now be within £22,000.

CHESTERTON.—The District Council recently invited the Cambridge Electric Light Company to tender for the public lighting of the district, but the Council have now received a letter the from Company stating that their powers do not extend beyond the borough of Cambridge, and consequently they could not send in a tender as requested.

COLLIERY LIGHTING.—The electric light is at present being installed at the Langwith Colliery. About 100 incandescents, varying from 16 to 50 c.p., will be employed. The contract is being executed by the Sheffield Electric Light and Power Company.

CORK.—Mr. W. W. Barrington held a Board of Trade inquiry last week at Cork in connection with the proposed construction of electric tramways in the city. Mr. Wm. Murphy, who is one of the promoters, gave particulars of the scheme, and said it was proposed to construct a tramway of 3ft. gauge and to equip the same electrically on the overhead trolley system.

Digitized by Google

GARSTON.—The Town Council have written to the Liverpool District Lighting Company, who are promoting a Provisional Electric Lighting Order for the district, asking whether they would be prepared to reduce the maximum price of current to 8d., as in the case of Liverpool, and whether they would undertake to supply any part of the district when required by the Council. In the event of an affirmative reply being given, it is probable that the Council will consent to the Company's application for an Order.

GLASGOW.—At the meeting of the City Council on Friday last, the report of the Tramways Committee recommended that a sub-committee be appointed to visit various places on the Continent where electric traction is employed, for the purpose of collecting information for the guidance of the Committee in their efforts to find a suitable system of mechanical traction for the tramways under their control. The recommendation was adopted.

GOOLE.—It has been decided to light the docks electrically.

GREAT YARMOUTH.—The Town Council are considering the question of the extension of the electric light mains to the North Quay. The electricity accounts for February show that the receipts exceeded the working expenses by £80. 2s. 9d.; but after allowing for interest, sinking fund charges, &c., there was a deficit of over £19. At present there are 6,987 lamps connected.

GRIMSBY.—The Public Lighting Committee have presented a report on the electric lighting question. The Town Council obtained a Provisional Order in 1894, but nothing has been done to comply with its provisions, and the Committee now recommend that the matter be proceeded with. A Sub-Committee has been appointed to obtain further information and report to the Council.

HARROGATE.—The Local Government Board have conditionally sanctioned the borrowing of £27,000 by the Town Council for electric lighting purposes.

HASLINGDEN.—The Town Council have decided to apply for a Provisional Order.

HELENSBURGH.—At a recent meeting of the Police Commissioners the Lighting Committee recommended the erection of 17 additional gas lamps. Mr. Bryden said that instead of extending their present antiquated system, the Committee should rather be empowered to consider the question of the introduction of the electric light. The town was very favourably situated, as there was an abundance of water power available. Provost Whyte endorsed this view, and stated that he was making some inquiries into the matter, and as soon as he had received complete details he would bring the subject before the ratepayers. Mr. Bryden's suggestion was in the meantime agreed to.

KIDDERMINSTER AND STOURPORT ELECTRIC TRAMWAY.—The Great Western Railway Company have lodged a petition praying to be heard by counsel against this Bill when the committee stage is reached.

LECTURE.—A lecture on "Electricity in Connexion with Building" was delivered by Mr. W. H. Preece, C.B., on the 4th inst., at Carpenters' Hall, London. The lecturer stated that at the present time there was practically no difference between the cost of electric light and gas. The cost of the production of electricity was being reduced, and he thought the time was not very far distant when, comparing the ordinary burner with the electric lamp, it would be cheaper than gas.

LIVERPOOL.—The City Engineer has been authorised to conduct experiments with a view to enabling the electric light to be used in the sewers during repairs and other operations.

MARYLEBONE (LONDON).—At the meeting of the Vestry, on Friday last, the Chairman of the Electric Light Committee (Mr. Brooke Hitching) succeeded in inducing the members to try an experiment in electric lighting. It is proposed to light Upper Regent-street, from Oxford-circus to the Langham Hotel, by means of arc lamps, at an annual cost of £180. The present gas lamps, which cost £150 per annum, yield 850 c.p., but the Vestry will obtain 6,000 c.p. from the arc lamps.

MONIFIETH (DUNDEE).—A public meeting will shortly be held to discuss the lighting question. There is a feeling in favour of the introduction of the electric light.

MONMOUTH.—At the special meeting of the Town Council on Tuesday, a letter was read from the Board of Trade approving the scheme for the introduction of the electric light into the town.

MOTOR-CARRIAGE EXHIBITION.—An influential gathering was held at the Mansion House, London, on Friday last, in connection with the Exhibition of Horse and Horseless Carriages to be held at the Crystal Palace in May next. Amongst the speakers were Sir David Salomons, who pointed out the advantages to be expected from mechanically-propelled vehicles, and the advisability of keeping the matter out of the hands of company promoters. Amongst those taking part in the meeting were Dr. John Hopkinson, Prof. D. E. Hughes and Major Floodpage.

OBITUARY.—The death is announced of Mr. Wm. Henry Lefevre, C.E., President of the Balloon Society, who expired at his residence at Kensington on Friday last. Mr. Lefevre was born at Jersey, where his remains were conveyed on Monday last. He was president of the Balloon Society from 1880.

PAISLEY.—In anticipation of the establishment of municipal electric lighting works in Paisley, the Town Council have decided to wire the Town Hall for the electric light.

PORTSMOUTH.—The balance sheet of the Electric Lighting Committee for the year 1895 shows that the receipts exceeded the expenditure by £2,463. 14s. 6d., a sum sufficient to pay a dividend of 3¾ per cent. on the Council's capital outlay. It is stated that the demand for current is increasing in a most gratifying manner.

THE USE OF ELECTRICITY FOR THE AGEING OF WINES.—It is stated that Italian wine merchants have reason to congratulate themselves on the introduction of the electrical process for the ageing of wines which has been lately introduced in the wine-producing provinces of Italy. The process is said to render possible the most extraordinary modifications in the bouquet and body of the vintage, and it is probable that within a short period the process will be adopted in connection with Californian, and even with Australian, wines. Owing to the richness of the soil in which the grapes are grown, some such process of dealing with the product would, it is believed, prove advantageous.

WANDSWORTH (LONDON).—The County of London and Brush Provincial Company have notified the District Board of Works that they are advised that the Board has exceeded its powers in granting to a local tradesman the right to open the streets for the purpose of laying down electric light mains for supplying current. This is undoubtedly the stand that should have been taken at the outset. Having obtained a Provisional Order for lighting the district, the Company are surely entitled to the protection of the Local Authority.

WINDSOR.—The Corporation have decided to transfer their Provisional Electric Lighting Order to a local company, which has been formed for the purpose of lighting Windsor and Eton electrically.

WIMBLEDON.—The Local Government Board have intimated to the District Council that they could not entertain the proposal of the Board to borrow money for electric lighting purposes until they had obtained a renewal of their licence from the Board of Trade, and only then for the period for which the renewal would extend. The matter was discussed at the last meeting of the Council; some of the members favoured an immediate application for an extension of the licence, while others suggested waiting till November, when an application for a Provisional Order could be made. The Council have decided to adopt the latter proposal.

WORCESTER.—At the last meeting of the City Council the Electricity Committee presented an elaborate statement of the working and cost of the Council's electric lighting station during 1895. The total capital expenditure to the end of the year amounted to £52,225. 15s. 9d., the revenue to £3,254. 7s. 4d., while the year's working came to £3,057. 10s. 7d., leaving a profit of £196. 16s. 8d. A sum of £893. 6s. 9d. had to be set aside for interest and £952. 13s. 4d. for sinking fund purposes, in all £1,846. 0s. 1d., leaving a deficiency of £1,549. 3s. 5d. Accompanying the Committee's statement was the report of the city electrical engineer (Mr. E. T. Ruthven Murray), which was given in our last issue. Alderman Williamson moved that the accounts be passed. A long discussion followed, but eventually the motion was passed. The Council also decided to erect 20 arc lamps in various parts of the city as recommended in Mr. Murray's report.

COMPANIES' MEETINGS AND REPORTS.

City of Bath Electric Lighting and Engineering Company (Limited).

The fifth annual general meeting of this Company was held at Bath on Saturday. The Chairman (Mr. T. O. Callender) moved the adoption of the following report:—

During the year the gross profit amounted to £1,570. 8s. 3d., and a much more efficient service has been given to consumers. After payment of bank charges and mortgage and debenture interest, there remains a net profit of £1,131. 0s. 3d., to which must be added £388. 0s. 9d. brought forward from 1894. This sum would enable the Directors to pay 4 per cent. on the Ordinary share capital of the Company and to carry forward about £150, but it has been considered expedient to place the amount to reserve account, after the payment of the Directors' fees. During the year the Company's business has increased in a very satisfactory manner. The revenue from the sale of current and from installations, &c., has risen from £5,067 in 1894 to £6,152. A continuous supply of current has been kept up throughout the year, and the increase in the profit over 1894 has taken place notwithstanding that this additional supply involves a serious loss throughout the summer months. The number of lamps conected is 11,231, an increase of 2,904 compared with 1894. The existing station plant is now well loaded, and as soon as the question of the Provisional Order is settled the advisability of putting down plant for an additional 15,000 lamps will be considered. All the expenses of keeping the plant in good condition have been charged against revenue. The running of the plant has been most satisfactory, and it is now in the highest state of efficiency. In consequence of the opposition of the Local Authority to the Company's application for a Provisional Order, a Board of Trade inquiry was held in March last, with the result that the Board could not see its way to dispense with the consent of the Authority. Last November the Company again gave notice of its intention to apply for a Provisional Order, and the Local Authority also made application for an Order. At the invitation of the Board of Trade a conference has been held between the Company and the Authority, at which the appointment of an independent valuer by the Board of Trade to report on the value of the Company's property was proposed. This proposal has been agreed to by the Directors and the Bath authorities. The Directors hope this independent valuation may prove useful in bringing the two parties to an agreement.

The CHAIRMAN said that during the year they had supplied a good deal more electrical energy than in previous years, and their customers had increased in number. They had also made more profit, and there was a substantial amount to their credit on the year's operations, and under ordinary circumstances they would have declared a dividend, but in view of the special circumstances in which they stood it was deemed safer to carry the amount forward than divide it at present. During the last few months they had done better than ever before, and there was every prospect of a satisfactory future if they could only come to terms with the authorities. The Chairman then referred to the Company's application for a Provisional Order, and stated that Prof. Kennedy had been appointed to act as valuer, in accordance with the suggestion of the Board of Trade. It would be noticed that the first of the instructions which had been given to the valuer by the Board recognised what the Company had done, and pointed out that they were entitled to some consideration in respect of their work. He therefore believed they would be able to present a very good case when Prof. Kennedy came down.

Mr. VAN TROMP seconded the motion.

Mr. RUDDOCK then moved that a dividend of 3 per cent. be declared, but after a short discussion the amendment was rejected, and the retiring Director (Mr. Van Tromp) and the auditors were then re-elected.

Dover Electricity Supply Company (Limited).

The second annual meeting of the shareholders of this Company was held on Wednesday last at the offices, Park-street, Dover. Sir William Crundall, who presided, moved the adoption of the following report:—

The expenditure on capital account for the period under review amounted to £23,037. 19s. 8d., making, with the expenditure of the previous year, a total of £48,259. 1s. 6d. The revenue account shows a loss upon the first nine months' working. This was largely due to the fact that the six months of lightest consumption, viz., from April till September, when the load was also abnormally light owing to the limited number of lamps connected, are included; but in December the revenue about balanced expenditure, and the Directors believe that by the end of the current year the Company will be earning revenue in excess of working expenses. During the year the generating station has been completed, the plant and machinery installed in complete working order, and a continuous supply of current is now available throughout the whole of the main business streets and in a considerable portion of the residential districts.

In October last exhaustive tests were made by Profs. A. B. W. Kennedy and Silvanus P. Thompson of the whole of the machinery in the station, with gratifying results, the efficiency of the plant being found to be very satisfactory. The Directors, with a view to promote the extended adoption of the light, have reduced the price of current, as from January 1st last, to 7d. per unit up to 12 units per annum per 8 c.p. lamp for lighting, and to 5d. per unit for current used for lighting in excess of such consumption, as well as for heating and power purposes. At the end of the year there was an equivalent of 4,125 8 c.p. lamps connected. It is stated that the prospects of obtaining further connections in the present year are very encouraging; the Lord Warden Hotel is to be fitted up for the electric light, and current is to be taken from the Company's mains. The arc lamps on the sea front and in some of the main streets have given satisfaction, and the Corporation has ordered 10 more lamps for Snargate-street, which have been in use since the beginning of the present year. The Chairman said that the Directors had reason to be satisfied with the position of the Company, bearing in mind the fact that they had not yet been working for a year. At the present time they had the equivalent of about 5,000 8 c.p. lamps connected, with promises of support in various directions, including the Lord Warden Hotel. They hoped that the reduction in price which had been made would induce many of the townspeople to adopt the light. It brought the price of the current down to nearly the price of gas, and he thought that in view of the luxurious light given by electricity, and the freedom from damage to health and to decorations, it would be recognised as true economy to instal it. He next referred to the prospect of the construction of electric tramways in Dover. The Provisional Order would be obtained in the summer, and he thought the Council would be compelled to carry out their scheme at an early date. He believed that the Company would be able to offer inducements for the supply of the current, which it would be in the interests of the Council and the ratepayers to accept rather than to go to the expense of laying down costly plant of their own.

The report and accounts were then adopted, the retiring Directors and the auditors re-elected, and the proceedings terminated with a vote of thanks to the Chairman, Directors, and staff.

Oxford Electric Company (Limited).

The ordinary general meeting of the shareholders of this Company was held at the offices, 45, Broad-street, Oxford, on the 6th inst., under the presidency of Sir Henry C. Mance.

The CHAIRMAN, in moving the adoption of the report and accounts, said that the progress of the Company had been very satisfactory, and its prospects were most promising. The commercial efficiency of their system had steadily improved, being now about 70 per cent. The number of customers had increased during the year from 154 to 225, the more important additions to their list of customers being Balliol College, Somerville Hall, additional lights in Exeter College, and the important installations of Messrs. Elliston and Cavell, the new Municipal Buildings and the Corn Exchange. The system of supply to the public lamps has been almost entirely altered. All the half-night lamps are now connected in series. The additions to the circuit, and the change from one system to the other, were effected by the Managing Engineer, Mr. McLean, without the slightest interference to the service. The all-night arc lamps still remain connected with the low-tension mains. When the half-night lamps are suppressed, that is to say, about midnight, each arc is replaced by two incandescent lamps. He had every confidence that the new public lighting contract would give even greater satisfaction to the public than the old one. On January 1st they had an equivalent of about 15,000 8-c.p. lamps connected, and he had every reason to anticipate that the increase during 1896 would be quite as encouraging as during the past year. It was obvious, therefore, that the increased demand required that they should supplement their means of production with additional plant. Their engineer had now under careful consideration plans and estimates which were intended to provide for possible requirements during the next three years. For these extensions it would be necessary to provide additional capital. He asked the shareholders to approve of the distribution of 3½ per cent. on the Ordinary shares.

The motion was seconded and duly carried.

The retiring Directors, Mr. Alderman Buckell and Mr. L. A. Selby Bigge, were then re-elected, and a vote of thanks to the Chairman terminated the proceedings.

Barcelona Tramways Company (Limited).

At the ordinary general meeting of this Company, on Wednesday last, the CHAIRMAN (Mr. E. M. Underdown, Q.C.), in referring to the question of electric traction, said that he had received some letters from shareholders who took exception to the proposed increase in the capital of the Company for introducing electric traction on their lines, but he thought that they had not mastered the position thoroughly. The Directors had, after long study, extending over two or three years, and having made a close examination of tramways in other places, and having made studies of all the different systems and been in communication with all persons who are working, or desirous of working, this system, come to the conclusion that electric traction is absolutely necessary in a town like Barcelona. They had to provide for the enormous increase in the traffic which had to be carried in that city. People were more disposed to use their conveyances, as they were now more and more going to live in the suburbs, and had, therefore, to come every day to the city for business purposes. If they had to provide sufficient horses to meet the large amount of traffic either at particular hours of the day or on particular days, the benefit obtained from meeting those requirements would be frittered away, because the horses would be idle during the time the large traffic does not take place. In horse traction there was no elasticity which would enable them to meet the extra demands of a temporary character, and that is precisely what electric traction could do, and without any large extra expense it was possible to run the number of cars to accommodate the traffic which might come to the line. Under these circumstances, and having studied the question thoroughly, the directors had come to the conclusion that the introduction of electric traction would not only give an income amply sufficient to pay whatever interest they might decide to pay upon the capital which they proposed to raise for the purpose of introducing the system, but it would largely increase the income payable upon the Ordinary shares. Not only were they going to keep up their dividend, but to largely increase it. They had made every pre-

Digitized by Google

paration to put themselves in a favourable position for introducing electric traction into Barcelona. They had acquired some additional land, and had made arrangements for acquiring other lands, with the object of being ready to carry out this work, and to consolidate their stables and depositories for their rolling stock and other matters in a more convenient way than at present. The Directors had, with some of the chief inhabitants and officials of Barcelona, visited Milan and Marseilles, in order to show to those gentlemen the working of electric tramways. That had given great satisfaction to the authorities, and the Directors were now asking for permission to introduce this system, and he believed that they would before long obtain the necessary authorisation.

Eastbourne Electric Light Company (Limited).

The report of the Directors of this Company, to be presented at the ordinary general meeting to be held on Monday next, states that there are 37 arcs and an equivalent of 14,206 8 c.p. incandescents in circuit, an increase of 2 arcs and 2,150 incandescents for the year. The gross profit amounted to £3,182. 2s., and after adding £400 to the depreciation fund, and paying Debenture and other interest, there remains a sum of £1,656 available for dividend. The Directors propose to add £300 to the reserve fund and to pay a dividend of £7. 10s. per cent. per annum, carrying forward £557. 5s.

A new boiler has been put in during the year, and the plant, mains and machinery of the Company are in excellent working order. The reserve for depreciation now amounts to £2,225.

The retiring Director is Mr. Harry Sutton, who offers himself for re-election, as do the auditors, Messrs. Hart Brothers, Tibbetts and Co.

Brush Electrical Engineering Company (Limited).

The Directors of this Company have issued an interim report for the half-year ended December 31st last, which states :—

The works have been fully employed on central station and other orders. No large contracts have been entered into, but the volume of smaller orders has been well maintained, and additional large contracts are in course of negotiation. The new type of direct-driven alternating plant has proved satisfactory, recent tests made by Profs. Kennedy and S. P. Thompson for the Dover Electricity Company having yielded very good results, both as regards the economy and efficiency of the machinery supplied by the Company. A specially favourable feature, to which attention is drawn, is that the machines remain practically cold after a prolonged run at full load.

Negotiations are proceeding for an amicable settlement of the Company's claim against the City of London Electric Lighting Company for plant supplied.

The Company's Austrian and Australasian branches are showing improved results. The development of electric traction is being actively pushed forward, and the Directors anticipate important orders from this source. The new high-speed engine designed by the Company's chief engineer has been fully developed and tested, and has given satisfactory results. Steps are now being taken to place it upon the market, and the Directors anticipate a large sale of these engines for general application, as well as for electrical purposes.

The Board are making efforts to institute and maintain economies in every department, and with this object the policy of concentration at the works at Loughborough is being consistently followed as opportunity arises, by expiration of leases or otherwise, for the disposal of the London premises. During the half-year the issue of £105,000 Four and a-Half per Cent. Redeemable Second Mortgage Debenture Stock, mentioned in the last report, has been offered to the shareholders, and £76,770 has been allotted. The balance is held in reserve for issue at a premium when necessary, but the Company's funds are ample for all present requirements.

The Directors state that they do not propose to declare an interim dividend, as they prefer to await the result of the complete financial year, which closes on June 30th.

NEW COMPANIES, STATUTORY RETURNS, &c.

BULLERS (LIMITED).—This Company was registered on March 4th, with a nominal capital of £100,000, divided into 10,000 Preference and a like number of Ordinary shares of £5 each, to acquire and take over as a going concern the business carried on by a company of the same name, with a view to such acquisition, to enter into and carry into effect an agreement to be made with the said old company, and to carry on the business of engineers and contractors, whether manufacturing, mechanical, electrical, telegraphic or otherwise, and iron and brass founders and workers, and to manufacture, produce, sell, let on hire and generally deal in electrical plant, electricity, electric power and other forms of energy. The subscribers are :—Messrs. Howard C. Jobson, Summer Hill, Kidderminster, engineer ; John T. Harris, Radford, Stone, engineer ; Edward J. Chambers, Castle Cottage, Dudley, engineer ; E. Percy Jobson, W. Greenhill, T. R. Griffiths, and H. C. Pinsent. The first Directors are Messrs. Howard C. Jobson, John T. Harris, Arthur K. Tharp and Edward J. Chambers.

CANUTE SYNDICATE (LIMITED).—This Company was registered on March 3rd, with a nominal capital of £1,500, in £1 shares, to acquire any patents, patent rights, concessions, or other rights, to use any invention relating to the utilisation of substances suitable for the manufacture of electrical fittings and appliances, and to use, develop and otherwise turn to account the same, and to manufacture, sell and deal in goods and articles made in accordance with such inventions.

HOLOPHANE (LIMITED).—During the week this Company, which has been formed for the purpose of acquiring the patent rights for all countries (except France and the United States) of Messrs. Blondel and Psaroudaki, inventors and patentees of the "Holophane" Globe, invited subscriptions for 65,000 £1 shares.

WILLIAMSON AND JOSEPH (LIMITED).—This Company was registered on March 9th, with a nominal capital of £10,000, divided into 5,000 £5 per Cent. Cumulative Preference shares and 5,000 Ordinary shares of £1 each, to acquire and take over the business referred to in an agreement with Edward L. Joseph, and to carry on the business of electrical and mechanical engineers, suppliers of electricity for light, heat and motive power purposes, and manufacturers of and dealers in all kinds of apparatus and things used for or capable of being used in connection with the generation, distribution, supply, accumulation and employment of electricity. The first subscribers, with one share each, are :—H. Glenister, C. E. Wellaby, F. C. Moore, T. M. Middleton, E. H. Minton, G. H. Congleton, and A. A. Jones. Mr. E. L. Joseph is to be one of the first Directors.

CAMBRIDGE ELECTRIC SUPPLY COMPANY (LIMITED).—The annual return to February 7th has been filed. 4,077 shares have been subscribed out of a capital of £50,000, in £10 shares. £8 per share has been called.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The annual return to February 26th has been filed. The whole nominal capital of £220,000 in 16,000 Ordinary and 6,000 Preference shares, of £10 each, has been taken up, and the full amount has been called and paid.

HOUSE TO HOUSE ELECTRIC LIGHT SUPPLY COMPANY (LIMITED).—The annual return to March 5th has been filed. The capital is £350,000 in 57,900 Ordinary, 100 Founders' and 12,000 Preference shares of £5 each. 8,322 Ordinary, 100 Founders' and 5,000 Preference have been taken up, and all the Founders' and 1,000 Ordinary have been issued as fully paid. The full amount has been called on the remainder.

CITY NOTES.

MEMORANDA.—Bank rate, 2 per cent. (Feb. 22, 1894). Price of silver 31 7/16d. per oz. (March 12th). Consols (2¾ per cent.) 109¾—110 for money, 109⅞—110 for account ; 2½ per cent. 106—106½ (March 12th). Stock Exchange Settling Days : Consols, March 30th ; Stocks and Shares Continuation Day, March 25th ; Ticket Day, March 26th ; Pay Day, March 27th ; Mining Share Carry-over Day, March 24th.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended March 8th, were £977, against £971 in the corresponding week of 1895, an increase of £6. The total receipts for the half-year amount to £9,837, against £9,911 for the corresponding period of 1895, a decrease of £74.

COMMERCIAL CABLE COMPANY.—The report of the Directors of this Company for the year 1895 states that the gross earnings amounted to $2,009,737, and the working and other expenses to $794,340, leaving a balance of $1,215,397. There was an increase in the earnings of $236,304, and in the expenses of $31,344, as compared with the previous year, resulting in an increase in net earnings of $204,959. Dividends of 1¾ per cent. for the quarters ended March 31st, June 30th, September 30th and December 31st have been paid—a total of 7 per cent. for the year on the capital stock—amounting to $700,000. The reserve fund has been augmented by the purchase of $200,000 United States Government Bonds. The balance of the year's profit, amounting to $315,397, remains to the credit of profit and loss. Six sections of the Company's cables were interrupted at different periods during the year, chiefly caused by contact with anchors of fishing vessels. The repairs were, however, promptly effected. The whole of the Company's system is in excellent condition.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The Directors of this Company have decided, subject to audit, to recommend the payment of dividends at the rate of 10 per cent. per annum on the Preference shares, and of 4 per cent. per annum, free of income tax, on the Ordinary shares, both for the half-year ended December 31, 1895.

IMPERIAL TRAMWAYS COMPANY (LIMITED).—The report of the Directors of this Company, to be submitted at the general meeting to be held at Bristol to-morrow (Saturday), states that as the Dublin Southern Tramways Company's lines were in course of reconstruction, the tramways have been closed to traffic for practically the whole of the period under review. The Directors, however, state that there is every prospect of the lines being ready for opening within the next few weeks. The Company are promoting a Bill in Parliament in the present Session with a view to obtaining powers for considerable extensions of their electric tramways in the city of Dublin and suburbs. The assents of all the suburban townships have been given to the Bill. The whole of the projected lines can be operated from the location of the Company's central power station. The Bill also provides for changing the name of this Company to the "Dublin Electric Tramways Company."

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended 8th inst. amounted to £1,040. The amount for the corresponding week last year was £937. Increase £103.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended March 6th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,777.

WESTERN UNION TELEGRAPH COMPANY.—The Directors of this Company have decided to recommend the payment of the usual quarterly dividend of 1¼ per cent. The quarterly statement of the Directors shows a deficit, after dividends, of $185,000, compared with $271,000. For the nine months to date the surplus is $389,000, against $298,000.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861—1878.

No. 931. [Vol. XXXVI. No. 21.] FRIDAY, MARCH 20, 1896. PRICE SIXPENCE.

NOTES.

THE discussion on Mr. ADDENBROOKE's Paper on "High Voltage Lamps and their Influence on Central Station Practice," was, for these days, unusually short and to the point. The lamp-makers had a fine field-day, and their remarks were noteworthy for their candour and explicitness. But the lamp-makers were not alone, far from it; they had the cordial support of the central-station engineer and the no less cordial opposition of the consultant and the alternate-current engineer.

IN regard to the question of high-efficiency *versus* high-voltage lamps, Mr. SWAN pointed out that it would be courting failure to place 2½ watt lamps on supply circuits subjected, as these are, to such undesirable variations of pressure; an 8-c.p. 2½-watt lamp was already sufficiently strained by 100 volts, and it had but a small factor of safety. From the consumer's point of view, therefore, as well as from that of the lamp maker and central-station engineer, the high-voltage lamp was to his mind to be preferred; it would be subjected in all probability to smaller variations of pressure than the 100-volt lamp, and neither he nor Mr. STEARN could see any *a priori* manufacturing reason for anticipating for it a short life or an appreciably lower efficiency than 3½ watts per candle. Mr. J. F. C. SNELL, of the St. Pancras staff, was able to assert from personal experience that a life of 1,300 hours was obtainable with 220-volt lamps, and his chief, Mr. SYDNEY BAYNES, naturally gave the Paper his benediction and passed on to the consideration of the arrangement of feeders and the working current density advisable for distributors.

BUT the progressists did not have it all their own way. Mr. GEIPEL said he knew a leading lampmaker who candidly admitted that a good 200-volt 3-watt 8-c.p. lamp could not be made at present, and without this desideratum Mr. GEIPEL would have nothing to do with the latest new thing; indeed, "he thought the 200-volt lamp policy a mere subterfuge, which should be strongly opposed." Mr. H. W. HANDCOCK was also a disbeliever in the efficiency, durability and suitability of the high-voltage lamp, and, like Mr. SWAN himself and other speakers, he was doubtful as to the reliability of existing wiring and fittings under the extra strain.

THE many advantages of a 200-volt lamp to the low-pressure central station engineer are in no need of exposition, but none the less Mr. ADDENBROOKE did good service in putting them all into black and white, and in thus affording lamp-makers an opportunity of taking us more or less into their confidence and of showing us their wares. The consumer's convenience must, however, be consulted, unless, indeed, in our "ardour for progress" we are to progress backwards. If the advent of the 200-volt lamp means to him no greater outlay on wiring, lamps and current, and, above all, no greater bother, he will, after his suspicions have been allayed, readily adopt it. On the other hand if it is to deprive him of a reliable 8-c.p. lamp, increase his outlay on wiring and lamps, and run up his quarterly bill for current, central station engineers will do incalculable harm by forcing the pace. Our advice is: Hold your hand. St. Pancras has 4,000 high-voltage lamps connected, Edinburgh will shortly have a still larger number; after a twelvemonth's experience in these two localities, we shall know exactly where we are. A false step in this matter will give the electric lighting industry a grievous set back The lamp-makers undoubtedly made out a very good case for themselves at the Institution last week, but even they would probably prefer a gradually increasing demand to a sudden rush. We cannot afford to increase either the trouble or the general expense of electric lighting, if it is ever to become the universal illuminant. When the lamp and the wiring questions are settled by actual experience, the economies resultant upon the higher pressure of distribution will enable the price of the Board of Trade unit to come down handsomely. But even a 2d. unit would scarcely be a complete compensation for unreliable lamps and expensive fittings.

WE publish this week in full the new wiring rules just issued by the St. Pancras Vestry. These are interesting as being the first of the kind drawn up since the 220-volt lamp came down from the high regions of pioneering experiment to the commercial level. Like all rules and regulations, these issued by Mr. BAYNES appear formidable when "taken in the loomp," but in the main they are such as would probably be voluntarily observed by a firm of good repute when carrying out a 220-volt wiring job which had not been let to the lowest tenderer. There are several stipulations which, we imagine, a wiring contractor may have well-grounded objections to, but there is a general air of determination and practical acquaintance with the work in hand about the St. Pancras rules; a distinct relief after the somewhat flaccid and academic tone of many rules it has been our painful duty to digest.

That some attempt is being made to effect the removal of tin from tin-plate scrap according to the principles laid down in Dr. Borchers' book, which was last week reviewed in these columns, is evident from the fact that in a recent German patent Herr Kotzur proposes to use caustic alkali as the electrolyte in a bath of which the anode is the scrap to be stripped, and provides for the inevitable deterioration of the electrolyte in the following way :—When the voltage required rises to an unremunerative height, a fraction of the electrolyte is removed and replaced by fresh caustic soda. The saturated material is freed from tin by treatment with carbon dioxide, which decomposes sodium stannate, leaving sodium carbonate in solution. The stannic oxide precipitated is free from impurity, and can be readily reduced to metallic tin, while the sodium carbonate may be causticised and used again. An alternative plan consists in precipitating the tin as calcium stannate by boiling the spent electrolyte with lime, and thus freeing the caustic solution from its acquired disability. The calcium stannate is then reduced to metallic tin by ordinary metallurgical methods.

Some researches have recently been undertaken by Mr. E. Taylor Jones with a view to ascertain whether the agreement between Maxwell's equation for, and the observed values of, magnetic tractive force at moderately large inductions also exists when much higher inductions occur. The analytical investigation is to be found in Vol. II., Chap. XI., of Clerk Maxwell's "Electricity and Magnetism," which treats of "Energy and Stress in the Electromagnetic Field," and the equation in question, $B^2/8\pi$, can be directly deduced from Maxwell's generalised equations on pp. 278-9 of that volume. Whether this equation for tractive force in terms of B is correct, or whether some alternative expression—such as the $2\pi I^2$, which has been given by Stefan and others—should be taken, Mr. E. T. Jones had already in a previous investigation sought to determine; but the relatively low values of magnetic induction—6,000 to 20,000 C.G.S. lines per square centimetre—and the relative insignificance of H, rendered it still doubtful whether or no H played the part implied by Maxwell's equation. To settle this latter point, it was necessary to carry on the investigations under conditions such that the first term in the expression $H + 4\pi I = B$ should become but an inconsiderable fraction of the whole; in other words, to measure the tractive force when the permeability was reduced to a small value.

The results appear to give a complete justification to Maxwell's $B^2/8\pi$ equation, to the discomfiture of the advocates of $2\pi I^2$, though it must be admitted that we have yet to receive the answer of these latter. Soft iron and glass, hard steel have been experimented upon by Mr. Jones, and the curve giving the relation between the square root of the observed tractive forces and the corresponding values of B, from 0 to 40,000 C.G.S. lines per square centimetre, is a straight line from which the departure of none of the observed values exceeds 3 per cent.; while the majority of the readings are very close indeed to their theoretical value, as given by Maxwell's equation. The soft iron was subjected to a maximum magnetising force $H = 17{,}690$, and a corresponding induction, $B = 39{,}260$, under which conditions a tractive force of 63,000 grm. per square centimetre was developed. The glass-hard wolfram steel sample was subjected to $H = 17{,}830$ and $B = 36{,}110$, and exhibited a tractive force of 52,900 grm. per square centimetre.

Maxwell's equation thus verified for all values of magnetic induction, it was an obvious corollary to employ it conversely in the determination of extremely high inductions. The permeameter of Prof. S. P. Thompson had already been devised for the measurement of inductions of common magnitude; but now the applicability of such an instrument where the induction was too high to be measured in other ways was proved. Accordingly inductions due to enormous magnetising forces were estimated from the tractive forces developed in a sample of iron or steel. And, if this method be correct under such conditions, inductions as high as 100,000 C.G.S. lines per square centimetre can exist in iron. It is interesting to notice that at this induction a force of no less than 3,185lb. per square inch was developed in the test piece, at the moment of its parting from the opposite pole-surface. A full account of these researches is contributed by their author to the current number of the *Phil. Mag.*

The forthcoming Berlin Industrial Exhibition, whatever it may or may not effect, is at any rate to be the scene of an interesting attempt to solve that hitherto insoluble problem of selecting a Jury of Awards which shall satisfy the exhibitors. The exhibitors in each department are to select their own judges. The mutual jealousies of the electors may certainly be expected to result in the election of an admirably open-minded jury; whether its members will be equally competent may be doubted. The idea, however, possesses the merit of originality and contains many of the elements of success.

Sir John Pender.—The statements that have appeared as to Sir John Pender's health are misleading. Though there is less immediate cause for anxiety than there was some weeks ago his condition is still very serious. There has been no substantial improvement, and he is quite incapable of attending to any business.

Cable Interruptions :—

	Date of Interruption.
Puerto Plata—Martinique	December 19, 1895
Aden—Zanzibar	March 16, 1896

The P.-Q. Cable.—We understand that the French cable ship François-Arago has lifted and buoyed the St. Pierre end of the P.-Q. cable in deep water.

New Books.—Messrs. Macmillan and Co. will publish the Miscellaneous Papers of Prof. Hertz, with an introduction by Prof. Lenard, the translation being done by Messrs. D. E. Jones and G. A. Scholt.

Municipal Purchase at Southampton.—At Wednesday's meeting of the Town Council, the proposal to purchase the undertaking of the Southampton Electric Light and Power Company, and to borrow £50,000 for that purpose and for extensions, was carried.

Prof. Schuster.—*Nature* states that the Committee of the Athenæum Club, acting under the provisions of the rule of the Club which empowers the annual election by the Committee of nine persons "of distinguished eminence in science, literature, the arts, or for public service," have admitted to membership Prof. Arthur Schuster, F.R.S.

The Royal Society.—The following papers were down for reading yesterday :—Capt. Abney, F.R.S., "The Photographic Value of Moonlight and Starlight compared with the Light of

Digitized by Google

a Standard Candle." Lord Blythswood on "The Reflection of Röntgen Light from Polished Speculum Metal Mirrors." J. R. Erskine Murray on "The Effect of the Röntgen X-rays on the Contact Electricity of Metals." C. T. R. Wilson, "The Effect of Röntgen Rays on Cloudy Condensation."

Royal Institution.—The following are some of the lecture arrangements after Easter:—Mr. C. Vernon Boys, three lectures on "Ripples in Air and on Water"; Prof. Dewar, three lectures on "Recent Chemical Progress." The Friday evening meetings will be resumed on April 17th, when a discourse will be given by M. G. Lippmann on "Colour Photography"; succeeding discourses will probably be given by Prof. Silvanus P. Thompson, Prof. J. A. Ewing, Prof. J. A. Fleming.

The Bilbao Telegraph Office and the Electric Tramway.—On the evening of the 16th inst. a telephone linesman at Bilbao, who was working on the roof of a house, accidentally dropped a roll of copper wire, which fell on the overhead wires of the Government telegraphs and the electric tramway. The telegraph wires were melted and the commutator and instruments in the Government telegraph office, which was only a few yards distant, were destroyed, and the instrument room set on fire, thus stopping for a time all Bilbao's inland telegraphic communications.

Serious Telephone Breakdown in Vienna.—On Monday, March 9th, a heavy snowstorm caused the destruction of a large part of the overhead network of the Vienna Telephone Exchange. Of the 8,980 subscribers, more than 4,000 were unable to make use of their instruments. The snow was of a sticky character and covered the wires to a thickness of 1¼in. This enormous weight broke down most of the wires, and also a great number of the cast-iron poles. Several interurban lines have suffered in the same way, and telephone communication has almost entirely been suspended.

The Goldsmiths' Company's Technical and Recreative Institute.—The New Cross Technical and Recreative Institute of the Goldsmiths' Company appears by its recent report to have met with greater success in the past year than heretofore. More than 1,000 entries in excess of the number for the previous year were registered, and the technical classes are very much patronised by the young people for whom they are held. Space does not permit us to mention all the excellent provisions which this Institute affords for recreation and study, but we may note that the classes in electrical subjects appear to be duly appreciated.

The Electrical Standardizing, Testing and Training Institution and X-Rays.—It may interest our readers to know that the authorities of Faraday House, Charing Cross Road, have placed in one of the private rooms the necessary apparatus for photographing by means of X-rays. This has been done at the suggestion of certain prominent members of the medical profession, and already a large number of negatives have been produced. The apparatus is of course manipulated by the staff of the Institution, but it is desirable that patients should be accompanied by a medical gentleman who is attending them.

"L'Industrie Électrique."—Our esteemed contemporary has found it necessary to make the following delightful apology for its issue of March 10th:—

"La composition de ce numéro, par suite d'un singulier concours de circonstances, diffère, par le manque de variété, de tous ceux qui l'ont précédé, bien qu'il renferme 52 pages au lieu de 24. D'une part, la quatrième édition de notre *Statistique des chemins de fer et tramways électriques*, en exploitation, en construction ou en projet, statistique dont l'importance n'échappera pas à nos lecteurs, occupe à elle seule 16 pages: d'autre part, les communications faites à l'Académie des sciences sur les rayons X, communications qu'il nous faut au moins résumer, se succèdent avec une abondance désespérante. Nos lecteurs voudront donc bien excuser le caractère un peu monotone de ce numéro. Il nous a paru utile de *liquider* toute l'Académie en une seule fois. Le prochain numéro reprendra son allure normale et présentera sa variété habituelle."

"Legal Fees for Technical Experts in Germany."—Under this heading the *Zeitschrift des Vereins Deutscher Ingenieure* for March 7th gives some interesting information with regard to the inadequate remuneration offered by the German Law Courts to technical experts. According to law the fee is fixed in proportion to the expert's income, namely 1s. 6d. per hour for an income under £300 per annum, and 2s. per hour for over that sum. In June last year a mechanical engineer of some standing was asked to act as technical expert in an important case. He furnished a long report and attended the trial. Sending in a £20 bill it was returned by the judge with the remark that according to paragraph so-and-so no round sum could be charged, but the number of hours was to be put down at 2s. each. A protest was entered into, but nothing was heard of it for some time, until one day the gentleman in question received the magnificent sum of £5, which the judge had fixed as sufficient remuneration for his time and trouble. On appealing to a higher court the committee of a leading engineers' society was asked to give an opinion as to what were the "usual" fees for expert work, and on receiving the answer the Court at once granted the full claim.

The Hermite Electrical Sanitation Process.—The installation of this system at the Military Hospital, Netley, has now been working since the beginning of the year, and a visit of inspection was, Messrs. Paterson and Cooper inform us, made a few days ago by the War Office authorities, who expressed themselves thoroughly satisfied both with the effect on the main sewer and the effluent, and also with the remarkable improvement in the atmosphere of the various wards. The ward-masters are also unanimous in their approval. The French War and Naval Departments have officially approved the system, and are considering to which of their stations it shall be first applied. The Brazilian Government have given instructions for the Marine State Hospital at Rio to be fitted with Hermite plant on the same lines as the Victoria Hospital, Netley. As to the success of the demonstrations of the Hermite process at Rio last year, it may be of interest to state that in that part of the city where the working of the plant has been continued, not a single case of yellow fever has occurred, though it is a most unsanitary spot, and in previous years has suffered severely. Other parts of the city have suffered as usual from the periodical visitations of this scourge.

Expiring Patents.—On Saturday will expire Prof. A. E. Dolbear's Patent No. 1358 of 1882, for "Improvements in Electric Cables," the improvements being a hollow insulating tube containing a bare conductor twisted with a wide helix of cotton. On Monday next, the 23rd inst., will expire Patent No. 1,412 of 1882, granted to Messrs. Woodhouse and Rawson for "Improvements in Electric Lighting and Apparatus Connected Therewith." The invention chiefly relates to the silvering of one half of an incandescent lamp bulb. On Wednesday next, the 25th inst., will expire Patent No. 1,444 of 1882, granted to Richard Werdermann, for "Improvements in Electric Incandescent Lighting Apparatus." The specification describes a semi-incandescent type of lamp, and the claims are for (1) "The fixed electrode enclosed within an air-tight globe, cylinder or chamber (which may or may not have a vacuum therein) and the moving electrode arranged to be kept in contact with the fixed electrode," and (2) "The combination, with the moving electrode, of the collar or ring of steatite, magnesia or other suitable refractory material." On Friday next, the 27th inst., will expire Patent No. 1,464 of 1882, granted to MM. Laland et Chaperon for the primary battery which bears their name.

The Coehn Carbon Consuming Cell.—A new proposal for making a galvanic cell consuming carbon was made by Dr. A. Coehn, in a communication to the Elektrotechnischer Verein of Berlin, on February 25th. The *Elektrotechnische Zeitschrift* for March 12th makes the following remarks on the subject:—"The investigation is based upon a fact which has been already observed by several other electro-chemists, but which has so far been found very inconvenient in electrolytical processes in which insoluble anodes are required. The carbons mostly employed have not, under the influence of the current in different liquids, shown sufficient resistance to disintegration. On the contrary, the carbons fell to pieces. In proceeding step by step and with experiments well arranged, Dr. Coehn has been able to find out the exact conditions required to enable the carbon to produce on oxidation only carbon dioxide (CO_2) and carbon monoxide (CO) on the anode. It was found that a certain temperature and a certain current density were necessary conditions, as electrolytic diluted sulphuric acid of a certain gravity was used. Dr. Coehn was further successful in depositing on

Digitized by Google

the cathode the carbon given off by the anode. This proves that the carbon or a compound of it plays an important part in the transport of the electricity through this liquid. To construct a cell which is based on the combination of carbon the necessary oxygen must be supplied to the cathode. This is done by employing peroxide of lead cathode. In such a carbon cell, with dilute sulphuric acid and a peroxide of lead cathode, an E.M.F. of 1·03 volts is obtained, and it works in such way that at the anode the carbon burns to carbon monoxide and carbon dioxide, while on the cathode peroxide of lead is reduced to metallic lead." Dr. Coehn's communication is shortly to be published in full.

Electric Propulsion of Canal Boats.—Mr. Charles R. Barnes, City Electrician, of Rochester, U.S.A., has made an official report on experiments in electric propulsion on the Erie Canal, a description of which was published in *The Electrician* of November 15, 1895, p. 88. For the purpose of the tests the State scow "Tonawanda" was used, and was towed up and down the experimental section a number of times, under varying conditions of wind and current. The "Tonawanda" weighed 60 tons, carried a load of 157½ tons, making a total displacement of 217½ tons, and drew 5½ft. of water. Each run was made over a distance of 0·4 mile, and an average speed of about 2½ miles per hour was attained at the expenditure of only about 8½ electrical horse-power for the 217½ tons towed. Taking these figures as a basis, together with the price at which the Erie Canal Traction Company is bound by virtue of its franchise to furnish electric power to boatmen—namely, not to exceed $20 per horse-power per season of navigation, which ordinarily covers 210 days—and assuming that the tow-motor worked constantly during the whole season, thus making 35 single trips between Buffalo and Troy with such vessels and at such speed as referred to, the cost per trip would be, assuming continuous work, about $5, or less than 1·4 cents per boat-mile. Now, assuming that during one-third of the entire time the motor remained idle at locks and elsewhere, although power was charged for just the same, then the cost per boat-mile covered would average 2·1 cents, or $7.66 per trip. If in addition to this a rental were charged for the motor, at the same rate per horse-power and season as for the electric power itself, for the entire time, including the periods of idleness, the total cost per boat-mile run would amount to 4·2 cents, or $15.32 per trip. At this rate not only would power be cheap to the consumer, but the renting out of motors, Mr. Barnes believes, would prove a profitable enterprise. If the boat speed were to be, say 3½ instead of 2½ miles per hour, the power would be increased from 8½ to about $23\frac{4}{10}$ electrical horse-power, the cost of the electric current from 2·1 cents to 4·1 cents per mile, and the item of motor depreciation or rental also from 2·1 cents to 4·1 cents; this would make, together, 8·2 cents per mile, or $29.93 per trip for the higher speed. A tow-motor running continuously would make 48 trips at the higher speed, against 35 trips at the lower speed per season; but if one-third the entire time were lost by delays, in either case there would still be made 32 trips at the higher or 23 trips at the lower speed per season. Of course the time allowance for delays, which is here assumed at one-third of the entire season, is an arbitrary one, and it seems rather unlikely that anywhere near as much time would necessarily be lost, especially not with the proposed improvements in the locks. Of the various systems that have been proposed or suggested for canal traction the towage system seems to appeal most favourably to boatmen, as only the towing facilities require to be changed from the mule or horse to the tow-motor. Another feature of some value is the absence of the wash unavoidable with propellers. The towage system, further, appears to afford greater flexibility of manipulation, as extra tow-motors could more readily and at less expense be kept in reserve at suitable points along the canal to meet odd demands than would be the case with propeller boats, and boats could be towed even singly or in couples with a fair degree of economy, not necessitating the making up of long trains as with propellers.

Röntgen Rays.—The *Comptes Rendus* of the Académie des Sciences continue to be well filled with Röntgeniana. In the issue of March 2nd (No. 9, 1896) M. D'Arsonval describes experiments, which he sums up as follows: "All bodies giving rise to greeny-yellow fluorescent radiation can *impress photographic plates through opaque bodies*. . . . It follows that the *rôle* of cathode rays in Röntgen's experiments would appear to be limited to fluorescing the special kind of glass of which the Crookes tubes is composed." M. Henri Becquerel in the same number refers to his previous brief announcement of experiments, showing the existence of *invisible* radiation emitted by certain phosphorescent substances and passing through bodies opaque to light. Such radiation is emitted by strips of the double sulphate of uranyl and potassium $[SO_4(UO)K + H_2O]$. MM. A. Imbert and H. Bertin-Sans made a communication on "The Diffusion of Röntgen Rays." They find that within the limits of their experiments Röntgen rays are regularly reflected to only a very slight extent; on the other hand, they may be much diffused, and the "intensity of the diffusion appears to depend much more on the nature than on the degree of polish of the diffusing body. A fact which tends to show that the new rays have a very small wave length such that it is impossible for us to attain the degree of polish necessary to cause regular reflection. The *clichés* obtained by us reveal, moreover, in quartz and cork different degrees of transparency in regard to the rays diffused by the different bodies used." MM. Bleunard and Labesse have a note on "The Passage of Röntgen Rays through Liquids." They state that water is very transparent, and, as has been previously observed, they find that colour has no perceptible influence. Solutions of bromide of potassium, chloride of antimony, bichromate of potash, offer "a somewhat considerable resistance to the passage of Röntgen rays." Solutions of borate of soda, permanganate of potash, are less resistant. In the *Comptes Rendus* for March 9th, M. Henri Becquerel describes further experiments with the invisible rays emitted by phosphorescent bodies, which do not emit *light* for more than about $\frac{1}{100}$th of a second after cessation of excitation. Electrified bodies are discharged. Using an Hurmuzescu electroscope, which, protected against electrical influence by a metal case and against ultra-violet light by yellow glass, can retain its charge for months, M. Becquerel found that on replacing some of the yellow glass by a strip of aluminium 0·12mm. thick, and applying a strip of the phosphorescent body to the outside, a charge was dissipated in 2h. 56min.; placing the phosphorescent body inside the case under the divergent gold leaves naturally resulted in their more rapid collapse. Experimenting with a view to discover how long after exposure to light these invisible rays continue to be emitted, M. Becquerel finds that with sesquioxide of uranium, double sulphate of uranyl and potassium, sulphate of sodium, and sulphate of ammonium, the power of the rays emitted is not sensibly diminished after 160 hours in the dark. In another series of experiments some sulphides of calcium giving blue, blue-green, and orange luminosity, some sulphide of strontium (green luminosity), and some hexagonal blende, all powdered, were placed in tubes closed at one end, and inverted on strips of glass 0·2mm. thick and sealed thereto with paraffin, the whole being placed on a sheet of aluminium 2mm. thick and put into a dark box with a photographic plate. After 13 hours the plate was developed, the blende, (orange) sulphide of calcium, and sulphide of strontium gave nothing, but the other two sulphides of calcium exhibited great activity. "The two images obtained with the two sulphides of calcium through the aluminium merit special notice as exhibiting important peculiarities," says M. Becquerel. "The quantity of phosphorescent powder contained in the tubes formed a column several millimetres high, and in the case of the blue sulphide, almost a centimetre high. The radiation from the lateral surface gave large very black spots, in the middle of which could be distinguished the light image of the section of the glass tube, and especially clearly the outline of the glass strips. These outlines, black inside and surrounded by an absolutely white line, show that the oblique radiation penetrated the glass strip, and was refracted and totally reflected at the surface of separation of the glass and the air." M. Becquerel also finds that air has no very marked absorbing effect on these rays.

THE AMAZON CABLE SYSTEM.

The great advantages of direct telegraphic communication with the many important towns on the banks of the Amazon are self-evident, and have long been recognised. In 1893 an attempt was made by the Brazilian Federal Government to establish a land line, but after a large outlay had been incurred the line had to be abandoned, owing to the difficulties experienced in the forests and swamps bordering on the river. Application was then made to Congress, with the result that by a contract made in April, 1895, the Federal Government granted a concession which includes important privileges—viz., the exclusive right for a term of 30 years to lay subfluvial cables in the zone comprised between Pará and Manaos; an annual subsidy of £17,125 during the first 20 years of the concession; all favours granted to similar enterprises in Brazil; permission to treat with the Governments of the States of Pará and Amazonas for the establishment of other branch cables, any subventions granted by these Governments to take effect without prejudice to the subsidy or other favour conferred by the Federal Government in the concession. At the expiration of the 30 years the system of cables will become the property of the Federal Government, which has also the power to purchase the undertaking after 10 years, at a price based on the value of the works and the average profit for the preceding five years, but not less than the capital sum expended by the Amazon Telegraph Company in laying down and working the cables. The cable is to connect the city of Manaos, more than 800 miles up the Amazon, the capital of the State of Amazonas and the chief market of the indiarubber trade in Brazil, with the important city of Pará at the mouth of the river, with intermediate stations or branch lines at Pinheiro, Mosqueiro, Souré, Cametá, Breves, Gurupá, Chaves, Macapá, Monte Alegre, Santarem, Alemquer and Obidos, all in the State of Pará, and Parintins and Itacoatiara in the State of Amazonas. At Pará the cable joins the land lines of the Brazilian Government, and is in touch with the cables of the Western and Brazilian Company, connecting with the rest of Brazil and the Argentine Republic, whilst through the cables of the Brazilian Submarine Company Manaos is in communication with Europe and the rest of the world.

The contract for the construction and laying of the cables, as well as for the supply of all the station material and repairing machinery, was placed with Messrs. Siemens Bros. and Co. in July last. The engineers for the Amazon Telegraph Company are Messrs. Clark, Forde and Taylor, under whose supervision the cables have been made and laid.

The total length of the cables is 1,365 nautical miles, and almost the whole of this is main cable, there being no intermediate cable, and but little shore end and beach cable. The core consists of a single 7-strand conductor, insulated with gutta-percha. For the main type of cable, this core is served with jute, sheathed with 12 galvanised steel wires, and finished off with two layers of jute and compound. For the short lengths of beach cable, or perhaps it would be more appropriate in this instance to call it "bank cable," the core is taped, covered with a continuous cold-drawn lead tube, served with jute, sheathed with 24 steel wires, and finished as usual. The shore ends are made by applying to the beach-cable a further sheathing of 12 steel wires again protected by jute and compound. The main cable measures nearly 1in. in diameter, and weighs 56cwt. per nautical mile; the beach cable $\frac{7}{8}$in., and 53cwt.; and the shore end 1$\frac{1}{2}$in., and 193cwt. The distances from station to station being comparatively short, the working is carried on with Siemens' double-current Morse instruments, with polarised relays.

Early in September last Mr. Alexander Siemens proceeded to Brazil, and directed a careful survey of the Amazon from Pará to Manaos, settling the route for the cable, and selecting the most suitable landing places. The cable has been laid quite up to Manaos by the "Faraday," to which the "Malvern" has acted as tender. The "Faraday," with Mr. Siemens in charge, sailed from the Thames in the middle of December last, and the first through message from Manaos was received in London on February 10th this year.

EXPERIENCE WITH THE ELECTRIC LOCOMOTIVE IN THE BALTIMORE TUNNEL.*

After a short period of experimental work, electric locomotive No. 1 on August 4, 1895, took up the regular freight service through the Belt Line Tunnel of the Baltimore and Ohio Railroad in the City of Baltimore. The tunnel, which is the largest "soft dirt" tunnel ever built, extends from the present Camden passenger station of the Baltimore and Ohio Railroad, a distance of 7,350 feet north under the heart of the city,

Shortly after locomotive No. 1 had been put into service, and had given an exhibition of its ability to haul the heaviest freight trains, it became a matter of general interest as to how much it could pull and how fast it could go. The locomotive was therefore given a trial at hauling several of the passenger trains at high speeds, which it did satisfactorily to all concerned. As the conditions for operating the passenger trains entirely by the electric locomotive could not, on account of track facilities, be perfected until the new Mount Royal station, at the northern portal of the tunnel, was completed, it was decided to operate them in the meanwhile by coke burning steam locomotives. The new Mount Royal station will be ready in April or before, and preparations are now being made to then operate all trains, both freight and passenger, by the electric locomotives.

It was shown, from the few trials made with passenger trains, that not only could the guaranteed speed of 30 miles an hour be attained, but speeds of 35 and 40 miles, with 500 ton trains, were possible. An exhibition of high speed was made with the locomotive running light up the 0·8 per cent. grade, and a speed of 61 miles per hour was attained for a short time, without the slightest trouble from trolley or motors. Several of the many exhibitions made by the locomotives in pulling heavy loads have been described in the newspapers. Probably the most striking was when two trains were coupled together and hauled through the tunnel. For some reason the freight trains had become "bunched" on the Washington division, and when they did get through they came so fast that it was decided to have the electric locomotive haul them two at a time. The first composite train, therefore, consisted of 44 cars, loaded with coal and lumber, two regular steam freight engines and a steam "pusher" engine. The whole weight was approximately 1,900 tons, and was equivalent to about 52 loaded cars. The steam locomotives did no work to assist the electric locomotive. The start was made easily and gradually, but when the train was in the tunnel and entirely on the grade the steady, heavy pull was too severe on a defective coupling near the head of the train, and it parted. After coupling together again, the electric locomotive started the heavy train, with all drawbars stretched—no slack in the train—and accelerated it to a speed of 12 miles an hour, without slipping a wheel, and in every way with the greatest ease. It reminded one of the start of an ocean steamship, so noiseless was it and free from any manifestations other than those of mighty power. The current recorded on the ammeter was about 2,200 amperes during the acceleration period, and after the train was up to speed it settled down to about 1,800 amperes. The voltage on the line was 625. By reading the amperes we were able to readily compute the drawbar pull, and found it to be about 63,000lb. All four motors were in series, and we were, therefore, getting the maximum pull for that current.

It may be of interest to steam railway engineers to know how we determined the drawbar pull exerted for each ampere of current put into the locomotive. The Pennsylvania Railroad Company's dynamometer car was secured and coupled in between the electric locomotive and a train of known weight. The weight of each car in pounds had been accurately determined beforehand. The regular two-mile haul up grade was then made. When the train was in the tunnel on the grade the pull was uniform, as was shown in the diagrams taken on the dynamometer car.

When no drawbar pull was recorded the pen rested on base line No. 1. The height or ordinate of the irregular curve at any point represented the drawbar pull at that instant. Measuring the same in inches and subtracting a constant and then multiplying by 4,000, gave the drawbar pull in pounds—*i.e*, every inch in height represented 4,000lb. The paper travelled under the pen at a rate proportional to that of the train. An irregular line marked No. 2, above the base line, was the planimeter record, from which was determined the mean pull for any time. Having, then, the velocity, or the feet per minute, and the mean pounds pull exerted during any period, we readily obtained the horse-power developed.

Another line on the diagram showed the chronograph record, each of the small offsets in the line occuring every five seconds. For every 100ft. the train moved the paper moved 1in. The distances in inches between any two of these offsets gave us readily the velocity of the train. Another line represented the time readings of current and voltage which were taken in the locomotive, a

* From the *Electrical Engineer* of New York.

Digitized by Google

push-button in the locomotive being electrically connected with this recording apparatus. These readings were numbered, so it was easy to tell the current at any time and location. Still another line showed a record of the different stations in the tunnel. From this we determined the location of the train at any time.

The first test showed (*a*) how the start was made on the down grade leading to the tunnel; (*b*) how, after the train was fully started, the drawbar pull dropped off; then (*c*) how it gradually increased as the train came on to the 0·8 per cent. grade in the tunnel; and (*d*) after the train was wholly on the grade, how even the pull was, until near the stop, when the grade increased 1·2 per cent. Mr. Dunbar, the official of the Pennsylvania Railroad Company in charge of the car, showed some diagrams of steam locomotive work under similar conditions, and it was seen that their amplitude of vibrations was considerably greater than those of the electric locomotive. This was undoubtedly due to the absence of the angle crank on the electric locomotive, and because its pull is uniform throughout the entire revolution of the armature. Most of the vibrations of the pen shown on these curves were due to vibrations of the dynamometer car which was mounted on a single truck.

From test No. 1 we obtained the total drawbar pull in pounds, and knowing the weight of the train we found the drawbar pull to be 22. + lbs per ton of weight. Subtracting the grade pull, which, in the case of an 0·8 per cent. grade, is 16lb., we obtained 6. + lbs. per ton as the train resistance. This confirms the usual allowances made for freight train resistance. These observations were taken in September, 1895, on a very hot day. During the past winter months the train resistance has increased, due, no doubt, to greater journal friction caused by thickened lubricants, and we find it to be from our records about 20 per cent. to 30 per cent. greater than in September.

Test No. 2 was made after we had switched off six cars. The run was made under similar conditions and the same character of observations was made. The difference in drawbar pull of the two trains would naturally be the drawbar pull necessary for the six cars switched off. We had their exact weight, and were thus again able to find what the drawbar pull per ton was. It was a check on our first figure, and was very close to it, the slight difference we found being due to one brake on the six cars being partially set during the first run and unknown to anyone.

We had the readings of current during the first run, also during the second. The difference of these should show the current required to haul six cars switched off. Dividing the difference in the drawbar pulls recorded in the two tests by the difference in current recorded, gives us directly the net drawbar pull in pounds per ampere of current. This was 28·6lb.

It will, of course, be noted that by this method we eliminated the current required to drive the locomotive. To determine how much this was, and to check our conclusions, we divided the drawbar pull in pounds recorded in the first by 28·6, and thus obtained the current that should exert that net drawbar pull. Subtracting this current from the current actually recorded on the locomotive would give the current required to drive the locomotive. We found it took 144 amperes. As a further check we figured similarly for the second test and obtained precisely the same, *i.e.*, 144 amperes. So at any time now when hauling a train with the four motors in series, if we take the current indicated on the amperemeter and substract the 144 amperes needed for the locomotive, and multiply the remainder by 28·6, we have the total net drawbar pull in pounds, and if we divide this by the drawbar pull per ton we get the tons of load we are pulling.

From the results obtained above we were able to show the current and drawbar pull at any moment while accelerating a train. The curves (Figs. 1 and 2) explain themselves very fully. The acceleration curve (Fig. 2), was obtained by dropping doughballs every two seconds, and they were the markers used in determining the distances travelled in each interval, as shown on the curves in Fig. 2.

When it comes to comparison of the economy of electric and steam locomotives it is readily seen that it is a difficult undertaking, knowing as we do the figures of only a single isolated electric plant operating under special conditions and for a comparatively short time. One great incidental advantage of electric locomotives in tunnel service is that they are smokeless. This is an important hygienic consideration, but one which can hardly be computed in dollars and cents. But it may be of general interest to know how the actual operating expenses per engine mile of the electric locomotives during October, 1895, compare with those of a prominent and large eastern railway for the same month.

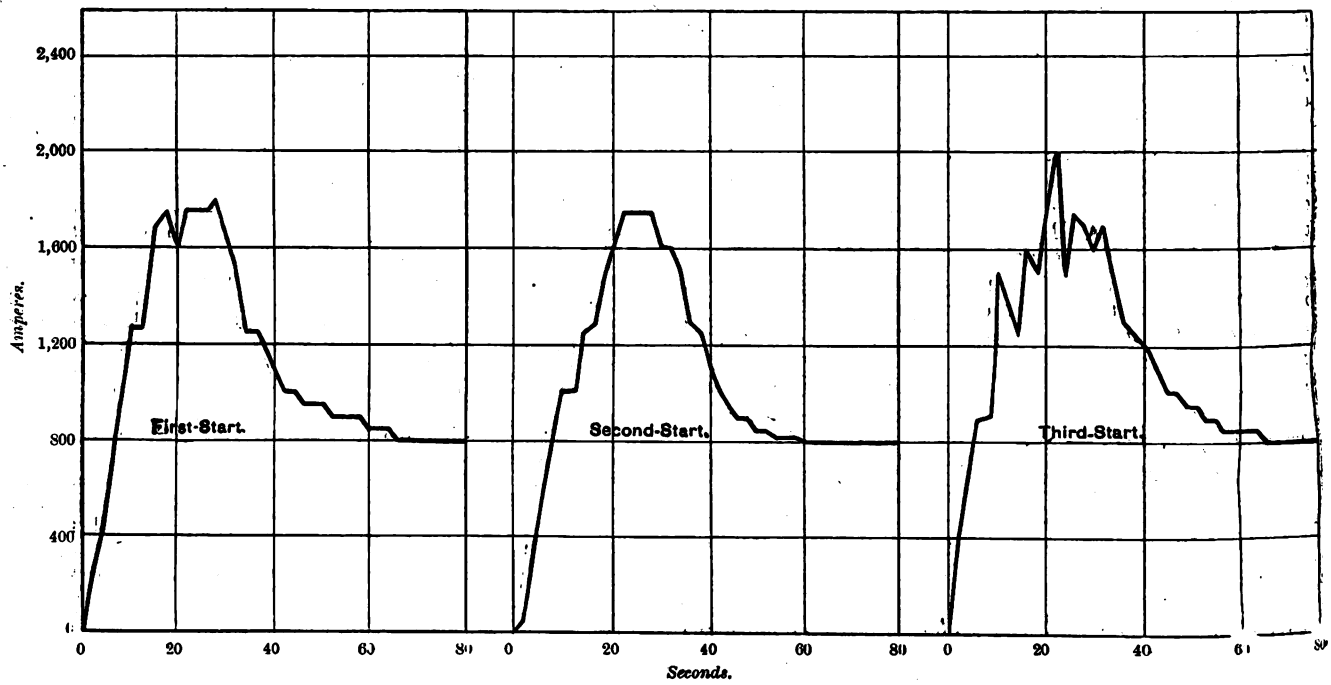

FIG. 1.—Current Record, two second readings. Three successive starts of a freight train on a grade of 0·8 per cent. Approximate weight of train, 875 tons.

For the operation of the Baltimore and Ohio tunnel power house for the month of October, 1895, the itemised expenses were as follows :—

Labour	$1,345.70
Coal ($1.35 per ton)	400.96
Oil and waste	151.26
Water	50.56
Maintenance	25.42
Total	$1,974.00

The expense of electric locomotives was :—

Motor engineers	$200.00
Oil and waste	12.16
Total	$212.16
Total expense	$2,186.16

There were hauled through the tunnel 353 trains.

Average weight of train	tons	1,095
Average time of trip	minutes	20
Average current	amperes	966
Distance of trip	miles	4
Total engine travel	miles	1,412
Total engine travel "idle"	miles	3,756
Actual time consumed for above service	hours	118
Idle time for month	hours	626

Digitized by Google

It is customary to consider an engine with steam up as equivalent to six engine miles for each hour it is idle, so that, for comparison, the actual mileage made by the engines must be increased $6 \times 626 = 3,756$ miles.

The large charge of labour at power house will be the same for one, two or three locomotives in service. The items, coal, water and maintenance, and the expense on locomotives, increase with the number of locomotives in service. If we assume this increase to be proportional, the total expense and cost per engine mile are as follows :—

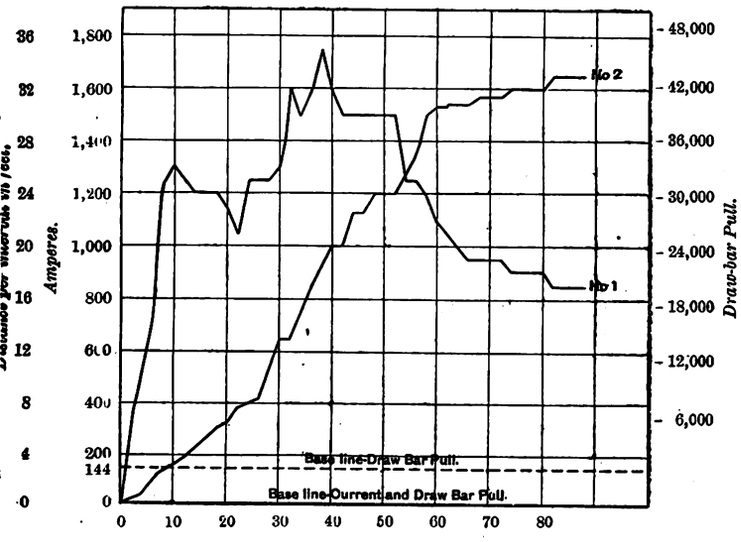
—	Total Cost.	En. miles.	Cost per en. mile.
For one locomotive	$2,186.16	5,168	$0·423
For two locomotives.....	2,875.36	10,336	0·278
For three locomotives	3,564.56	15,504	0·23

The steam railway records referred to above are for October, 1895, and may be briefly abstracted as follows :—

Steam Locomotive Performance.

—	East div.	West div.	Cen. div.	N.&W. div.	Entire Line.
Locomotives in service	74	57	33	28	192
Av. engine mileage in service	2,834	2,966	2,293	2,305	2,703
Average cost per engine mile—					
Passenger engines	0·1926	0·1666	0·1629	0·1552	0·1765
Freight engines	0·2472	0·2656	0·3428	0·2303	0·2615
Switching engines	0·1489	0·1659	0·1828	0·1425	0·1577
Work engines	0·2391	0·2258	0·2617	0·2169	0·2354
Total Engines	0·2080	0·2183	0·2121	0·1797	0·2095

From the figures given above it is seen that the actual operating expenses of the electric locomotives for that particular month are about the same as for the freight locomotives on the steam railroad, *i.e.*, 23 cents per engine mile. The service of the electric locomotives at that time was only about one-third that which it is expected they will have to do when the passenger service is taken up and the line extended the full distance.



No. 1.—Current and Draw-bar Pull.
No 2.—Acceleration, feet per interval of two seconds.

FIG. 2.—Electric Locomotive, B. and O., No. 1. Current and Torque and Speed Record of the start of a freight train of 28 loads and two dead engines on a grade of 8 per cent. Weight of train, 910 tons.

As originally intended, a method of using to advantage the power of the station while the electric locomotives are idle is soon to be incorporated in the plant. Under the new conditions, the cost per engine mile for the electric locomotives will be far under that of steam.

A comparison of the efficiencies of steam and electric locomotives shows slightly in favour of the electric. Observations made on French railways and on the Pennsylvania Railroad show that about 45 per cent. to 55 per cent. only of the indicated horse-power of steam locomotives is applied to hauling trains. The efficiency of the Baltimore and Ohio plant is in the vicinity of 60 to 65 per cent. under normal conditions.

A word may be added as to our experience with the overhead conductor system. The conductor in the tunnel has now been in position for nine months. During all of this time coke-burning locomotives have been used for passenger service, with the consequent presence of a good deal of gas and vapour. For the first six months about half of the conductor was constantly wet from the drip due to leaks in the masonry. This occasioned a muddy, slimy deposit over the insulators, and a considerable portion of the conductor. The porcelain insulators are almost entirely obscured in some places by this deposit, and that of small particles of carbon given by the locomotives.

Current was first turned on the line about three months after the tunnel structure was erected. The leak to earth was at first 21 amperes, but in a day or two this dropped to about 4 amperes—the present leakage. The inside of the conductor was coated with a combined deposit of rust and muddy sediment. Heavy currents were taken from it by the contact shoe only with difficulty and the presence of much arcing, heating and showers of sparks. It was found impracticable to run on this surface. By applications of kerosene and frequent scraping with special shoes, a direct contact of the trolley shoe with the conductor was made possible. Although a single contact shoe then worked with little or no sparking, two shoes in tandem were adopted. Their operation through the conductor is smoother, and the contact over muddy portions of it is more nearly positive. At intervals of about three weeks the conductor is treated with kerosene, and brushing shoes are run through it, about one or two trips with these brushing shoes being all that is necessary. This serves to prevent the further accumulation of rust, and to remove the sediment from the contact surfaces. An inspection shows a smooth surface over which the shoes run. Contact with the metal is seen to be in high spots and thin lines which are slowly increasing in extent. No considerable sparking now occurs, except at the wet places, where it is occasioned by the presence of water and sediment. With the exception of three places, about 200ft. long each, the conductor is at present dry.

The bolts to the arch of the tunnel are both galvanised and painted. They show no signs of rusting. The painting has, in general, protected the surface of the conductor and channels. The sides and top of the inside of the conductor are coated with rust. Most of this is hard and close gained, some of it, however, flaky. In no case is there apparent a reduction of thickness of any of the ironwork due to rusting. Outside the tunnels the conductor is in uniformly good condition. It adapts itself to changes of temperature without trouble. The inside of the conductor is coated with rust, but in no case has there been any trouble from it. The deposit appears to be very light. There was at no time any sparking between contact shoes and conductor outside of the tunnel.

FLYWHEEL ACCIDENTS IN POWER STATIONS.*

The recent flywheel accidents, although of the utmost importance to street railway and electric light companies, seem to have attracted very little attention. The Hoboken accident has been referred to, as a rule, in a most misleading manner, and the result of the investigation held by the Company some time after the accident seems to have been overlooked. The Albany accident appears to have attracted still less attention, though coming, as it did, shortly after the other, and being the cause of several deaths, it should have been of deep interest to all liable to the same casualty.

The Hoboken accident is laid by the owners to the carelessness of the engineer, and is consequently of little interest, since it shows no fault in the design or operation of the plant and machinery.

An inquiry made of the employés in the Albany power house the day succeeding the accident brought out as answers to some natural questions the statement that there was no apparent electrical trouble, and that while the plant was in normal operation under light load an engine was seen to gain speed. The engineer noticed it and immediately closed the throttle, which action of his did not interfere with its increasing speed. Running to the switchboards he cut the dynamo belted to that engine out and turned around just in time to see the wheel flying to pieces. No fuse had melted, and the generator remained in circuit until cut out by the engineer. Accepting as true that the throttle was closed in time, we can only surmise that the generator belted to the wrecked engine had been driven as a motor by the other generators feeding the same lines. This cause of the accident seems perfectly clear, and it is remarkable that there have been no such accidents before.

The plant consisted of two 500-kilowatt generators compounded for a line loss of about 10 per cent., and driven separately by Corliss engines of like capacity. In addition there were several smaller generators, driven in pairs by high-speed engines. Under the severe requirements of railway work, engines are liable to vary considerably in speed. The two 500-kilowatt generators and two of the smaller ones were connected in parallel to the lines, and if one of the engines lost speed from any cause, there was a possibility of the current from the stronger machines sending current backward through the lagging one. This is particularly liable to

* From the *Electrical World* of New York.

Digitized by Google

happen when the load is light, and is a common occurrence, understood by every electrician who has spent much time in a railway power station.

What is liable to happen in such a case is as follows: The shunt field-winding would still keep the field magnetism in the same direction, but, the direction of the current through the armature being reversed, the generator would be driven forward as a motor. The series winding would then contain a current flowing in an opposite direction to that in the shunt winding, and would consequently tend to weaken the fields of the machine and increase the current flowing through it. Indeed, the influence of the series winding is usually strong enough to so weaken the fields as to cause enough current to flow through the machine to operate the automatic brake commonly used. This would not necessarily follow, as the immense force exerted would quickly speed the generator and engine attached to it until it would develop a counter E.M.F., with its weakened fields equal to the E.M.F. of the generators driving it. The E.M.F. of the driven machine once lowered, it is a matter of some time to get it back, notwithstanding the increased speed; and the heavy current that would flow until a balance was effected would leave the fields in the same condition as at starting, when it required a very considerable period of time to build up the fields to their normal strength. Sometimes an engine will give way under such an unusual speed as would thus be attained before a balance was reached.

The danger is not so great from small generators as from large ones, and the time taken for a machine to attain its normal voltage when running at full speed is a fair comparison as to its liability to run away. The greater the proportion of series winding, the greater also the danger. From the instant the current starts to move the reverse way through the armature, it increases in quantity of flow, slowly sometimes on account of the time taken to reduce the magnetism of the fields by reason of their mass and construction, and the higher speed of the engine as its load is entirely removed; this follows because the action of the current in the field windings is more rapid than the gain in speed of the weighty engine, until the engine after a time gets a start and brings up its speed with a rush, increasing its E.M.F., and at the same time decreasing the current flowing through it.

The element of time in the strengthening or weakening of a large field magnet is so considerable that the writer has frequently seen one 500-kilowatt generator being reversed by its mate driven by the same pulley, and by quickly strengthening its field by a turn of the field rheostat has brought it back to its work as a generator. Were it not for the element of time in changing the strength of the magnets, no physical movement would be quick enough to check an action that is theoretically as instantaneous as the flow of electricity where there is so little self-inductance. It is this element of time in changing the strength of the fields that will cause an engine to run away.

The cure is as simple as the disease. A spring switch, the spring held in place by a compound magnet balanced by a weight, the magnet wound with both the main wire and the field shunt, and also so balanced as to hold the weight while both currents were in the same direction, and to release it when they opposed each other; this could easily be made and would prove effectual. A prop to hold up the weight could be arranged similar to that commonly used to hold up the governor weights on Corliss engines for convenience in starting.

ELECTRIC SUPPLY IN GERMANY.

The *Elektrotechnische Zeitschrift* for March 5th contains some tables showing the state of the electric supply business in Germany. There were on October 1st, 1895, 180 central stations in operation and 82 in progress or definitely decided on; of these latter, however, several have meanwhile commenced supply. Continuous-current is still the leading system, and is represented by 80 per cent. of the total output and by 74 per cent. of the total number of stations. Table I gives an analysis of the different systems. Of the continuous-current stations, 73 per cent. possess accumulators, the total capacity of which is about 30 per cent. of the total dynamo output of those stations. Table II. shows the different motive powers employed, steam leading with 55 per cent. of total capacity and 82 per cent. of the total number of stations. The largest central station is the Mauerstrasse station in Berlin, which has a dynamo capacity of 3,146 kilowatts. Then follow others at Hamburg, Berlin, Frankfort-on-Main, Leipzig, Munich, &c. In all there are 23 large stations, 58 of medium size, and the remainder which represent half the total are stations with dynamo capacities under 100 kilowatts. The 180 stations are distributed over 168 towns. Connected to the supply mains there are 602,986 50-watt glow lamps (England, 2¼ million 35-watt lamps), 15,396 10-ampere arc lamps, and motors to the extent of 10,254 H.P. These figures compared with last year show an increase of 22 per cent. in glow lamps, 24½ per cent. in arc lamps, and 82 per cent. in motors.

TABLE I.

System.	Number of stations.	Capacity of dynamos (kilowatts).	Capacity of batteries (kilowatts).	Total capacity of stations (kilowatts).
